Modify the parameters of a previously defined dump command. Not all parameters are relevant to all dump styles.

As explained on the dump doc page, the atom/mpiio, custom/mpiio, and xyz/mpiio dump styles are identical in command syntax and in the format of the dump files they create, to the corresponding styles without “mpiio”, except the single dump file they produce is written in parallel via the MPI-IO library. Thus if a dump_modify option below is valid for the atom style, it is also valid for the atom/mpiio style, and similarly for the other styles which allow for use of MPI-IO.

Unless otherwise noted, the following keywords apply to all the various dump styles, including the dump image and dump movie styles.

The append keyword applies to all dump styles except cfg and xtc and dcd. It also applies only to text output files, not to binary or gzipped or image/movie files. If specified as yes, then dump snapshots are appended to the end of an existing dump file. If specified as no, then a new dump file will be created which will overwrite an existing file with the same name.

The at keyword only applies to the netcdf dump style. It can only be used if the append yes keyword is also used. The N argument is the index of which frame to append to. A negative value can be specified for N, which means a frame counted from the end of the file. The at keyword can only be used if the dump_modify command is before the first command that causes dump snapshots to be output, e.g. a run or minimize command. Once the dump file has been opened, this keyword has no further effect.

The buffer keyword applies only to dump styles atom, cfg, custom, local, and xyz. It also applies only to text output files, not to binary or gzipped files. If specified as yes, which is the default, then each processor writes its output into an internal text buffer, which is then sent to the processor(s) which perform file writes, and written by those processors(s) as one large chunk of text. If specified as no, each processor sends its per-atom data in binary format to the processor(s) which perform file writes, and those processor(s) format and write it line by line into the output file.

The buffering mode is typically faster since each processor does the relatively expensive task of formatting the output for its own atoms. However it requires about twice the memory (per processor) for the extra buffering.

The delay keyword applies to all dump styles. No snapshots will be output until the specified Dstep timestep or later. Specifying Dstep < 0 is the same as turning off the delay setting. This is a way to turn off unwanted output early in a simulation, for example, during an equilibration phase.

The element keyword applies only to the dump cfg, xyz, and image styles. It associates element names (e.g. H, C, Fe) with LAMMPS atom types. See the list of element names at the bottom of this page.

In the case of dump cfg, this allows the AtomEye visualization package to read the dump file and render atoms with the appropriate size and color.

In the case of dump image, the output images will follow the same AtomEye convention. An element name is specified for each atom type (1 to Ntype) in the simulation. The same element name can be given to multiple atom types.

In the case of xyz format dumps, there are no restrictions to what label can be used as an element name. Any white-space separated text will be accepted.
The `every` keyword can be used with any dump style except the `dcd` and `xtc` styles. It does two things. It specifies that the interval between dump snapshots will be set in timesteps, which is the default if the `every` or `every/time` keywords are not used. See the `every/time` keyword for how to specify the interval in simulation time, i.e. in time units of the `units` command. The `every` keyword also sets the interval value, which overrides the dump frequency originally specified by the `dump` command.

The `every` keyword can be specified in one of two ways. It can be a numeric value in which case it must be > 0. Or it can be an equal-style variable, which should be specified as `v_name`, where name is the variable name.

In this case, the variable is evaluated at the beginning of a run to determine the next timestep at which a dump snapshot will be written out. On that timestep the variable will be evaluated again to determine the next timestep, etc. Thus the variable should return timestep values. See the stagger() and logfreq() and stride() math functions for equal-style variables, as examples of useful functions to use in this context. Other similar math functions could easily be added as options for equal-style variables. Also see the next() function, which allows use of a file-style variable which reads successive values from a file, each time the variable is evaluated. Used with the `every` keyword, if the file contains a list of ascending timesteps, you can output snapshots whenever you wish.

Note that when using the variable option with the `every` keyword, you need to use the `first` option if you want an initial snapshot written to the dump file. The `every` keyword cannot be used with the dump `dcd` style.

For example, the following commands will write snapshots at timesteps 0,10,20,30,100,200,300,1000,2000,etc:

```plaintext
variable s equal logfreq(10,3,10)
dump 1 all atom 100 tmp.dump
dump_modify 1 every v_s first yes
```

The following commands would write snapshots at the timesteps listed in file tmp.times:

```plaintext
variable f file tmp.times
variable s equal next(f)
dump 1 all atom 100 tmp.dump
dump_modify 1 every v_s
```

**Note:** When using a file-style variable with the `every` keyword, the file of timesteps must list a first timestep that is beyond the current timestep (e.g. it cannot be 0). And it must list one or more timesteps beyond the length of the run you perform. This is because the dump command will generate an error if the next timestep it reads from the file is not a value greater than the current timestep. Thus if you wanted output on steps 0,15,100 of a 100-timestep run, the file should contain the values 15,100,101 and you should also use the dump_modify first command. Any final value > 100 could be used in place of 101.

The `every/time` keyword can be used with any dump style except the `dcd` and `xtc` styles. It does two things. It specifies that the interval between dump snapshots will be set in simulation time, i.e. in time units of the `units` command. This can be useful when the timestep size varies during a simulation run, e.g. by use of the `fix dt/reset` command. The default is to specify the interval in timesteps; see the `every` keyword. The `every/time` command also sets the interval value.

**Note:** If you wish dump styles `atom`, `custom`, `local`, or `xyz` to include the simulation time as a field in the header portion of each snapshot, you also need to use the dump_modify `time` keyword with a setting of `yes`. See its documentation below.

Note that since snapshots are output on simulation steps, each snapshot will be written on the first timestep whose associated simulation time is \( \geq \) the exact snapshot time value.
As with the \texttt{every} option, the \textit{Delta} value can be specified in one of two ways. It can be a numeric value in which case it must be \(>0.0\). Or it can be an \textit{equal-style variable}, which should be specified as \texttt{v\_name}, where \texttt{name} is the variable name.

In this case, the variable is evaluated at the beginning of a run to determine the next simulation time at which a dump snapshot will be written out. On that timestep the variable will be evaluated again to determine the next simulation time, etc. Thus the variable should return values in time units. Note the current timestep or simulation time can be used in an \textit{equal-style variables} since they are both thermodynamic keywords. Also see the \texttt{next()} function, which allows use of a file-style variable which reads successive values from a file, each time the variable is evaluated. Used with the \textit{every/time} keyword, if the file contains a list of ascending simulation times, you can output snapshots whenever you wish.

Note that when using the variable option with the \textit{every/time} keyword, you need to use the \texttt{first} option if you want an initial snapshot written to the dump file. The \textit{every/time} keyword cannot be used with the dump \texttt{dcd} style.

For example, the following commands will write snapshots at successive simulation times which grow by a factor of 1.5 with each interval. The \texttt{dt} value used in the variable is to avoid a zero result when the initial simulation time is 0.0.

\begin{verbatim}
variable       increase equal 1.5*(time+dt)
dump          1 all atom 100 tmp.dump
dump_modify   1 every/time v\_increase first yes
\end{verbatim}

The following commands would write snapshots at the times listed in file \texttt{tmp.times}:

\begin{verbatim}
variable       f file tmp.times
variable       s equal next(f)
dump          1 all atom 100 tmp.dump
dump_modify   1 every/time v\_s
\end{verbatim}

\textbf{Note: } When using a file-style variable with the \textit{every/time} keyword, the file of timesteps must list a first time that is beyond the time associated with the current timestep (e.g. it cannot be 0.0). And it must list one or more times beyond the length of the run you perform. This is because the dump command will generate an error if the next time it reads from the file is not a value greater than the current time. Thus if you wanted output at times 0,15,100 of a run of length 100 in simulation time, the file should contain the values 15,100,101 and you should also use the dump\_modify first command. Any final value \(>100\) could be used in place of 101.

The \texttt{first} keyword determines whether a dump snapshot is written on the very first timestep after the dump command is invoked. This will always occur if the current timestep is a multiple of \$N\$, the frequency specified in the \texttt{dump} command or \texttt{dump\_modify every} command, including timestep 0. It will also always occur if the current simulation time is a multiple of \textit{Delta}, the time interval specified in the doc:\texttt{dump\_modify every/time \texttt{<dump\_modify>}} command.

But if this is not the case, a dump snapshot will only be written if the setting of this keyword is \texttt{yes}. If it is \texttt{no}, which is the default, then it will not be written.

Note that if the argument to the \texttt{dump\_modify every} doc:\texttt{dump\_modify every/time \texttt{<dump\_modify>}} commands is a variable and not a numeric value, then specifying \texttt{first yes} is the only way to write a dump snapshot on the first timestep after the dump command is invoked.

The \texttt{flush} keyword determines whether a flush operation is invoked after a dump snapshot is written to the dump file. A flush insures the output in that file is current (no buffering by the OS), even if LAMMPS halts before the simulation completes. Flushes cannot be performed with dump style \texttt{xtc}.
The `colname` keyword can be used to change the default header keyword for dump styles: `atom`, `custom`, and `cfg` and their compressed, ADIOS, and MPIIO variants. The setting for `ID string` replaces the default text with the provided string. `ID` can be a positive integer when it represents the column number counting from the left, a negative integer when it represents the column number from the right (i.e., `-1` is the last column/keyword), or a custom dump keyword (or compute, fix, property, or variable reference) and then it replaces the string for that specific keyword. For `atom` dump styles only the keywords “id”, “type”, “x”, “y”, “z”, “ix”, “iy”, “iz” can be accessed via string regardless of whether scaled or unwrapped coordinates were enabled or disabled, and it always assumes 8 columns for indexing regardless of whether image flags are enabled or not. For dump style `cfg` only changes to the “auxiliary” keywords (6th or later keyword) will become visible.

The `colname` keyword can be used multiple times. If multiple `colname` settings refer to the same keyword, the last setting has precedence. A setting of `default` clears all previous settings, reverting all values to their default names.

The `format` keyword can be used to change the default numeric format output by the text-based dump styles: `atom`, `local`, `custom`, `cfg`, and `xyz` styles, and their MPIIO variants. Only the `line` or `none` options can be used with the `atom` and `xyz` styles.

All the specified format strings are C-style formats, e.g., as used by the C/C++ `printf()` command. The `line` keyword takes a single argument which is the format string for an entire line of output for each atom (do not include a trailing “n”), with N fields, which you must enclose in quotes if it is more than one field. The `int` and `float` keywords take a single format argument and are applied to all integer or floating-point quantities output. The setting for `M string` also takes a single format argument which is used for the Mth value output in each line, e.g., the fifth column is output in high precision for “format 5 %20.15g”.

**Note:** When using the `line` keyword for the `cfg` style, the first two fields (atom ID and type) are not actually written into the CFG file, however you must include formats for them in the format string.

The `format` keyword can be used multiple times. The precedence is that for each value in a line of output, the `M` format (if specified) is used, else the `int` or `float` setting (if specified) is used, else the `line` setting (if specified) for that value is used, else the default setting is used. A setting of `none` clears all previous settings, reverting all values to their default format.

**Note:** Atom and molecule IDs are stored internally as 4-byte or 8-byte signed integers, depending on how LAMMPS was compiled. When specifying the `format int` option you can use a “%d”-style format identifier in the format string and LAMMPS will convert this to the corresponding 8-byte form if it is needed when outputting those values. However, when specifying the `line` option or `format M string` option for those values, you should specify a format string appropriate for an 8-byte signed integer, e.g., one with “%ld”, if LAMMPS was compiled with the `-DLAMMPS_BIGBIG` option for 8-byte IDs.

**Note:** Any value written to a text-based dump file that is a per-atom quantity calculated by a `compute` or `fix` is stored internally as a floating-point value. If the value is actually an integer and you wish it to appear in the text dump file as a (large) integer, then you need to use an appropriate format. For example, these commands:

```plaintext
compute 1 all property/local batom1 batom2
dump 1 all local 100 tmp.bonds index c_1[1] c_1[2]
dump_modify 1 format line "%d %0.0f %0.0f"
```

will output the two atom IDs for atoms in each bond as integers. If the `dump_modify` command were omitted, they would appear as floating-point values, assuming they were large integers (more than 6 digits). The “index” keyword should use the “%d” format since it is not generated by a compute or fix, and is stored internally as an integer.
The fileper keyword is documented below with the nfile keyword.

The header keyword toggles whether the dump file will include a header. Excluding a header will reduce the size of the dump file for data produced by pair tracker or bpm bond styles which may not require the information typically written to the header.

The image keyword applies only to the dump atom style. If the image value is yes, 3 flags are appended to each atom’s coords which are the absolute box image of the atom in each dimension. For example, an x image flag of -2 with a normalized coord of 0.5 means the atom is in the center of the box, but has passed through the box boundary 2 times and is really 2 box lengths to the left of its current coordinate. Note that for dump style custom these various values can be printed in the dump file by using the appropriate atom attributes in the dump command itself.

The label keyword applies only to the dump local style. When it writes local information, such as bond or angle topology to a dump file, it will use the specified label to format the header. By default this includes 2 lines:

```
ITEM: NUMBER OF ENTRIES
ITEM: ENTRIES ...
```

The word “ENTRIES” will be replaced with the string specified, e.g. BONDS or ANGLES.

The maxfiles keyword can only be used when a ‘*’ wildcard is included in the dump file name, i.e. when writing a new file(s) for each snapshot. The specified Fmax is how many snapshots will be kept. Once this number is reached, the file(s) containing the oldest snapshot is deleted before a new dump file is written. If the specified Fmax <= 0, then all files are retained.

This can be useful for debugging, especially if you don’t know on what timestep something bad will happen, e.g. when LAMMPS will exit with an error. You can dump every timestep, and limit the number of dump files produced, even if you run for 1000s of steps.

The nfile or fileper keywords can be used in conjunction with the “%” wildcard character in the specified dump file name, for all dump styles except the dcd, image, movie, xtc, and xyz styles (for which “%” is not allowed). As explained on the dump command doc page, the “%” character causes the dump file to be written in pieces, one piece for each of P processors. By default P = the number of processors the simulation is running on. The nfile or fileper keyword can be used to set P to a smaller value, which can be more efficient when running on a large number of processors.

The nfile keyword sets P to the specified Nf value. For example, if Nf = 4, and the simulation is running on 100 processors, 4 files will be written, by processors 0,25,50,75. Each will collect information from itself and the next 24 processors and write it to a dump file.

For the fileper keyword, the specified value of Np means write one file for every Np processors. For example, if Np = 4, every fourth processor (0,4,8,12,etc) will collect information from itself and the next 3 processors and write it to a dump file.

The pad keyword only applies when the dump filename is specified with a wildcard “*” character which becomes the timestep. If pad is 0, which is the default, the timestep is converted into a string of unpadded length, e.g. 100 or 12000 or 2000000. When pad is specified with Nchar > 0, the string is padded with leading zeroes so they are all
the same length = $N_{\text{char}}$. For example, pad 7 would yield 0000100, 0012000, 2000000. This can be useful so that post-processing programs can easily read the files in ascending timestep order.

The `pbc` keyword applies to all the dump styles. As explained on the `dump` doc page, atom coordinates in a dump file may be slightly outside the simulation box. This is because periodic boundary conditions are enforced only on timesteps when neighbor lists are rebuilt, which will not typically coincide with the timesteps dump snapshots are written. If the setting of this keyword is set to `yes`, then all atoms will be remapped to the periodic box before the snapshot is written, then restored to their original position. If it is set to `no` they will not be. The `no` setting is the default because it requires no extra computation.

The `precision` keyword only applies to the dump `xtc` style. A specified value of $N$ means that coordinates are stored to $1/N$ nanometer accuracy, e.g. for $N = 1000$, the coordinates are written to $1/1000$ nanometer accuracy.

The `refresh` keyword only applies to the dump `custom`, `cfg`, `image`, and `movie` styles. It allows an “incremental” dump file to be written, by refreshing a compute that is used as a threshold for determining which atoms are included in a dump snapshot. The specified `c_ID` gives the ID of the compute. It is prefixed by “c_” to indicate a compute, which is the only current option. At some point, other options may be added, e.g. fixes or variables.

**Note:** This keyword can only be specified once for a dump. Refreshes of multiple computes cannot yet be performed.

The definition and motivation of an incremental dump file is as follows. Instead of outputting all atoms at each snapshot (with some associated values), you may only wish to output the subset of atoms with a value that has changed in some way compared to the value the last time that atom was output. In some scenarios this can result in a dramatically smaller dump file. If desired, by post-processing the sequence of snapshots, the values for all atoms at all timesteps can be inferred.

A concrete example is a simulation of atom diffusion in a solid, represented as atoms on a lattice. Diffusive hops are rare. Imagine that when a hop occurs an atom moves more than a distance $D_{\text{hop}}$. For any snapshot we only want to output atoms that have hopped since the last snapshot. This can be accomplished with something the following commands:

```plaintext
variable Dhop equal 0.6
variable check atom "c_dsp[4] > v_Dhop"
compute dsp all displace/atom refresh check
dump 1 all custom 20 tmp.dump id type x y z
dump_modify 1 append yes thresh c_dsp[4] > ${Dhop} refresh c_dsp
```

The `compute displace/atom` command calculates the displacement of each atom from its reference position. The “4” index is the scalar displacement; 1,2,3 are the xyz components of the displacement. The `dump_modify thresh` command will cause only atoms that have displaced more than 0.6 Angstroms to be output on a given snapshot (assuming metal units). However, note that when an atom is output, we also need to update the reference position for that atom to its new coordinates. So that it will not be output in every snapshot thereafter. That reference position is stored by `compute displace/atom`. So the `dump_modify refresh` option causes a call to `compute displace/atom` at the end of every dump to perform that update. The `refresh check` option shown as part of the `compute displace/atom` command enables the compute to respond to the call from the dump command, and update the appropriate reference positions. This is done by defining an `atom-style variable`, `check` in this example, which calculates a Boolean value (0 or 1) for each atom, based on the same criterion used by `dump_modify thresh`.

See the `compute displace/atom` command for more details, including an example of how to produce output that includes an initial snapshot with the reference position of all atoms.
Note that only computes with a refresh option will work with dump_modify refresh. See individual compute doc pages for details. Currently, only compute displace/atom supports this option. Others may be added at some point. If you use a compute that does not support refresh operations, LAMMPS will not complain; dump_modify refresh will simply do nothing.

The region keyword only applies to the dump custom, cfg, image, and movie styles. If specified, only atoms in the region will be written to the dump file or included in the image/movie. Only one region can be applied as a filter (the last one specified). See the region command for more details. Note that a region can be defined as the “inside” or “outside” of a geometric shape, and it can be the “union” or “intersection” of a series of simpler regions.

The scale keyword applies only to the dump atom style. A scale value of yes means atom coords are written in normalized units from 0.0 to 1.0 in each box dimension. If the simulation box is triclinic (tilted), then all atom coords will still be between 0.0 and 1.0. A value of no means they are written in absolute distance units (e.g. Angstroms or sigma).

The sfactor and tfactor keywords only apply to the dump xtc style. They allow customization of the unit conversion factors used when writing to XTC files. By default they are initialized for whatever units style is being used, to write out coordinates in nanometers and time in picoseconds. I.e. for real units, LAMMPS defines sfactor = 0.1 and tfactor = 0.001, since the Angstroms and fs used by real units are 0.1 nm and 0.001 ps respectively. If you are using a units system with distance and time units far from nm and ps, you may wish to write XTC files with different units, since the compression algorithm used in XTC files is most effective when the typical magnitude of position data is between 10.0 and 0.1.

The sort keyword determines whether lines of per-atom output in a snapshot are sorted or not. A sort value of off means they will typically be written in indeterminate order, either in serial or parallel. This is the case even in serial if the atom_modify sort option is turned on, which it is by default, to improve performance. A sort value of id means sort the output by atom ID. A sort value of N or -N means sort the output by the value in the Nth column of per-atom info in either ascending or descending order.

The dump local style cannot be sorted by atom ID, since there are typically multiple lines of output per atom. Some dump styles, such as dcd and xtc, require sorting by atom ID to format the output file correctly. If multiple processors are writing the dump file, via the “%” wildcard in the dump filename and the nfile or fileper keywords are set to non-default values (i.e. the number of dump file pieces is not equal to the number of procs), then sorting cannot be performed.

In a parallel run, the per-processor dump file pieces can have significant imbalance in number of lines of per-atom info. The balance keyword determines whether the number of lines in each processor snapshot are balanced to be nearly the same. A balance value of no means no balancing will be done, while yes means balancing will be performed. This balancing preserves dump sorting order. For a serial run, this option is ignored since the output is already balanced.

Note: Unless it is required by the dump style, sorting dump file output requires extra overhead in terms of CPU and communication cost, as well as memory, versus unsorted output.

The thermo keyword only applies the dump styles netcdf and yaml. It triggers writing of thermo information to the dump file alongside per-atom data. The values included in the dump file are identical to the values specified by thermo_style.

The thresh keyword only applies to the dump custom, cfg, image, and movie styles. Multiple thresholds can be specified. Specifying none turns off all threshold criteria. If thresholds are specified, only atoms whose attributes meet all the threshold criteria are written to the dump file or included in the image. The possible attributes that can be tested for are
the same as those that can be specified in the *dump custom* command, with the exception of the *element* attribute, since it is not a numeric value. Note that a different attributes can be used than those output by the *dump custom* command. E.g. you can output the coordinates and stress of atoms whose energy is above some threshold.

If an atom-style variable is used as the attribute, then it can produce continuous numeric values or effective Boolean 0/1 values which may be useful for the comparison operator. Boolean values can be generated by variable formulas that use comparison or Boolean math operators or special functions like gmask() and rmask() and grmask(). See the *variable command* page for details.

The specified value must be a simple numeric value or the word LAST. If LAST is used, it refers to the value of the attribute the last time the dump command was invoked to produce a snapshot. This is a way to only dump atoms whose attribute has changed (or not changed). Three examples follow.

```plaintext
dump_modify ... thresh ix != LAST
```

This will dump atoms which have crossed the periodic x boundary of the simulation box since the last dump. (Note that atoms that crossed once and then crossed back between the two dump timesteps would not be included.)

```plaintext
region foo sphere 10 20 10 15
variable inregion atom rmask(foo)
dump_modify ... thresh v_inregion |^ LAST
```

This will dump atoms which crossed the boundary of the spherical region since the last dump.

```plaintext
variable charge atom "(q > 0.5) || (q < -0.5)"
dump_modify ... thresh v_charge |^ LAST
```

This will dump atoms whose charge has changed from an absolute value less than 1/2 to greater than 1/2 (or vice versa) since the last dump. E.g. due to reactions and subsequent charge equilibration in a reactive force field.

The choice of operators listed above are the usual comparison operators. The XOR operation (exclusive or) is also included as "|^". In this context, XOR means that if either the attribute or value is 0.0 and the other is non-zero, then the result is “true” and the threshold criterion is met. Otherwise it is not met.

The *time* keyword only applies to the dump *atom, custom, local, and xyz* styles (and their COMPRESS package versions *atom/gz, custom/gz* and *local/gz*). For the first 3 styles, if set to *yes*, each frame will will contain two extra lines before the “ITEM: TIMESTEP” entry:

```plaintext
ITEM: TIME
<elapsed time>
```

For the *xyz* style, the simulation time is included on the same line as the timestep value.

This will output the current elapsed simulation time in current time units equivalent to the *thermo keyword time*. This is to simplify post-processing of trajectories using a variable time step, e.g. when using *fix dt/reset*. The default setting is *no*.

The *units* keyword only applies to the dump *atom, custom, and local* styles (and their COMPRESS package versions *atom/gz, custom/gz* and *local/gz*). If set to *yes*, each individual dump file will contain two extra lines at the very beginning with:

```plaintext
ITEM: UNITS
<units style>
```

This will output the current selected *units* style to the dump file and thus allows visualization and post-processing tools to determine the choice of units of the data in the dump file. The default setting is *no*.
The *unwrap* keyword only applies to the dump *dcd* and *xtc* styles. If set to *yes*, coordinates will be written “unwrapped” by the image flags for each atom. Unwrapped means that if the atom has passed through a periodic boundary one or more times, the value is printed for what the coordinate would be if it had not been wrapped back into the periodic box. Note that these coordinates may thus be far outside the box size stored with the snapshot.

The COMPRESS package offers both GZ and Zstd compression variants of styles atom, custom, local, cfg, and xyz. When using these styles the compression level can be controlled by the *compression_level* keyword. File names with these styles have to end in either .gz or .zst.

GZ supports compression levels from -1 (default), 0 (no compression), and 1 to 9. 9 being the best compression. The COMPRESS /gz styles use 9 as default compression level.

Zstd offers a wider range of compression levels, including negative levels that sacrifice compression for performance. 0 is the default, positive levels are 1 to 22, with 22 being the most expensive compression. Zstd promises higher compression/decompression speeds for similar compression ratios. For more details see [http://facebook.github.io/zstd/](http://facebook.github.io/zstd/).

In addition, Zstd compressed files can include a checksum of the entire contents. The Zstd enabled dump styles enable this feature by default and it can be disabled with the *checksum* keyword.

### 16.44.4 Restrictions

Not all *dump_modify* options can be applied to all dump styles. Details are in the discussions of the individual options.

#### 16.44.5 Related commands

*dump, dump image, undump*

### 16.44.6 Default

The option defaults are

- *append = no*
- *balance = no*
- *buffer = yes* for dump styles *atom, custom, loca*, and *xyz*
- *element = “C”* for every atom type
- *every = whatever it was set to via the dump command*
- *fileper = # of processors*
- *first = no*
- *flush = yes*
- *format = %d and %g for each integer or floating point value*
- *image = no*
- *label = ENTRIES*
- *maxfiles = -1*
• nfile = 1
• pad = 0
• pbc = no
• precision = 1000
• region = none
• scale = yes
• sort = off for dump styles atom, custom, cfg, and local
• sort = id for dump styles dcd, xtc, and xyz
• thresh = none
• units = no

16.45 dump molfile command

16.45.1 Syntax

dump ID group-ID molfile N file format path

• ID = user-assigned name for the dump
• group-ID = ID of the group of atoms to be imaged
• molfile = style of dump command (other styles atom or cfg or dcd or xtc or xyz or local or custom are discussed on the dump doc page)
• N = dump every this many timesteps
• file = name of file to write to
• format = file format to be used
• path = file path with plugins (optional)

16.45.2 Examples

dump mf1 all molfile 10 melt1.xml hoomd
dump mf2 all molfile 10 melt2-*.pdb pdb .
dump mf3 all molfile 50 melt3.xyz xyz ./home/akohlmey/vmd/plugins/LINUX/molfile
16.45.3 Description

Dump a snapshot of atom coordinates and selected additional quantities to one or more files every N timesteps in one of several formats. Only information for atoms in the specified group is dumped. This specific dump style uses molfile plugins that are bundled with the VMD molecular visualization and analysis program.

Unless the filename contains a * character, the output will be written to one single file with the specified format. Otherwise there will be one file per snapshot and the * will be replaced by the time step number when the snapshot is written.

**Note:** Because periodic boundary conditions are enforced only on timesteps when neighbor lists are rebuilt, the coordinates of an atom written to a dump file may be slightly outside the simulation box.

The molfile plugin API has a few restrictions that have to be honored by this dump style: the number of atoms must not change, the atoms must be sorted, outside of the coordinates no change in atom properties (like type, mass, charge) will be recorded.

The *format* keyword determines what format is used to write out the dump. For this to work, LAMMPS must be able to find and load a compatible molfile plugin that supports this format. Settings made via the *dump_modify* command can alter per atom properties like element names.

The *path* keyword determines which in directories. This is a “path” like other search paths, i.e. it can contain multiple directories separated by a colon (or semi-colon on windows). This keyword is optional and default to “.”, the current directory.

The *unwrap* option of the *dump_modify* command allows coordinates to be written “unwrapped” by the image flags for each atom. Unwrapped means that if the atom has passed through a periodic boundary one or more times, the value is printed for what the coordinate would be if it had not been wrapped back into the periodic box. Note that these coordinates may thus be far outside the box size stored with the snapshot.

Dumps are performed on timesteps that are a multiple of N (including timestep 0) and on the last timestep of a minimization if the minimization converges. Note that this means a dump will not be performed on the initial timestep after the dump command is invoked, if the current timestep is not a multiple of N. This behavior can be changed via the *dump_modify first* command, which can be useful if the dump command is invoked after a minimization ended on an arbitrary timestep. N can be changed between runs by using the *dump_modify every* command. The *dump_modify every* command also allows a variable to be used to determine the sequence of timesteps on which dump files are written.

16.45.4 Restrictions

The *molfile* dump style is part of the MOLFILE package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

Molfile plugins provide a consistent programming interface to read and write file formats commonly used in molecular simulations. The MOLFILE package only provides the interface code, not the plugins. These can be obtained from a VMD installation which has to match the platform that you are using to compile LAMMPS for. By adding plugins to VMD, support for new file formats can be added to LAMMPS (or VMD or other programs that use them) without having to re-compile the application itself. The plugins are installed in the directory: <VMD-HOME>/plugins/<VMDARCH>/molfile
Note: while the programming interface (API) to the plugins is backward compatible, the binary interface (ABI) has been changing over time, so it is necessary to compile this package with the plugin header files from VMD that match the binary plugins. These header files in the directory: <VMDHOME>/plugins/include For convenience, the package ships with a set of header files that are compatible with VMD 1.9 and 1.9.1 (June 2012)

16.45.5 Related commands

dump, dump_modify, undump

16.45.6 Default

The default path is “.”. All other properties have to be specified.

16.46 dump netcdf command

16.47 dump netcdf/mpiio command

16.47.1 Syntax

dump ID group-ID netcdf N file args
dump ID group-ID netcdf/mpiio N file args

• ID = user-assigned name for the dump
• group-ID = ID of the group of atoms to be imaged
• netcdf or netcdf/mpiio = style of dump command (other styles atom or cfg or dcd or xtc or xyz or local or custom are discussed on the dump doc page)
• N = dump every this many timesteps
• file = name of file to write dump info to
• args = list of atom attributes, same as for dump_style custom

16.47.2 Examples

dump 1 all netcdf 100 traj.nc type x y z vx vy vz
dump_modify 1 append yes at -1 thermo yes
dump 1 all netcdf/mpiio 1000 traj.nc id type x y z
dump 1 all netcdf 1000 traj.*.nc id type x y z
16.47.3 Description

Dump a snapshot of atom coordinates every N timesteps in Amber-style NetCDF file format. NetCDF files are binary, portable and self-describing. This dump style will write only one file on the root node. The dump style netcdf uses the standard NetCDF library. All data is collected on one processor and then written to the dump file. Dump style netcdf/mpiio uses the parallel NetCDF library and MPI-IO to write to the dump file in parallel; it has better performance on a larger number of processors. Note that style netcdf outputs all atoms sorted by atom tag while style netcdf/mpiio outputs atoms in order of their MPI rank.

NetCDF files can be directly visualized via the following tools:

OVITO (http://www.ovito.org/). OVITO supports the AMBER convention and all extensions of this dump style.

• VMD (http://www.ks.uiuc.edu/Research/vmd/).

• AtomEye (http://www.libatoms.org/). The libAtoms version of AtomEye contains a NetCDF reader that is not present in the standard distribution of AtomEye.

In addition to per-atom data, thermo data can be included in the dump file. The data included in the dump file is identical to the data specified by thermo_style.

16.47.4 Restrictions

The netcdf and netcdf/mpiio dump styles are part of the NETCDF package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

The netcdf and netcdf/mpiio dump styles currently cannot dump string properties or properties from variables.

16.47.5 Related commands

dump, dump_modify, undump

16.48 dump vtk command

16.48.1 Syntax

dump ID group-ID vtk N file args

• ID = user-assigned name for the dump

• group-ID = ID of the group of atoms to be dumped

• vtk = style of dump command (other styles atom or cfg or dcd or xtc or xyz or local or custom are discussed on the dump doc page)

• N = dump every this many timesteps

• file = name of file to write dump info to

• args = same as arguments for dump_style custom
16.48.2 Examples

```
dump dmpvtk all vtk 100 dump*.myforce.vtk id type vx fx

```

16.48.3 Description

Dump a snapshot of atom quantities to one or more files every N timesteps in a format readable by the VTK visualization toolkit or other visualization tools that use it, e.g. ParaView. The timesteps on which dump output is written can also be controlled by a variable; see the `dump_modify every` command for details.

This dump style is similar to `dump_style custom` but uses the VTK library to write data to VTK simple legacy or XML format depending on the filename extension specified for the dump file. This can be either `*.vtk` for the legacy format or `*.vtp` and `*.vtu`, respectively, for XML format; see the VTK homepage for a detailed description of these formats. Since this naming convention conflicts with the way binary output is usually specified (see below), the `dump_modify binary` command allows setting of a binary option for this dump style explicitly.

Only information for atoms in the specified group is dumped. The `dump_modify thresh and region` commands can also alter what atoms are included; see details below.

As described below, special characters ("*", "%") in the filename determine the kind of output.

**Warning:** Because periodic boundary conditions are enforced only on timesteps when neighbor lists are rebuilt, the coordinates of an atom written to a dump file may be slightly outside the simulation box.

**Warning:** Unless the `dump_modify sort` option is invoked, the lines of atom information written to dump files will be in an indeterminate order for each snapshot. This is even true when running on a single processor, if the `atom_modify sort` option is on, which it is by default. In this case atoms are re-ordered periodically during a simulation, due to spatial sorting. It is also true when running in parallel, because data for a single snapshot is collected from multiple processors, each of which owns a subset of the atoms.

For the `vtk` style, sorting is off by default. See the `dump_modify` page for details.

The dimensions of the simulation box are written to a separate file for each snapshot (either in legacy VTK or XML format depending on the format of the main dump file) with the suffix `_boundingBox` appended to the given dump filename.

For an orthogonal simulation box this information is saved as a rectilinear grid (legacy .vtk or .vtr XML format).

Triclinic simulation boxes (non-orthogonal) are saved as hexahedrons in either legacy .vtk or .vtu XML format.

Style `vtk` allows you to specify a list of atom attributes to be written to the dump file for each atom. The list of possible attributes is the same as for the `dump_style custom` command; see its page for a listing and an explanation of each attribute.

**Note:** Since position data is required to write VTK files the atom attributes “x y z” do not have to be specified explicitly; they will be included in the dump file regardless. Also, in contrast to the `custom` style, the specified `vtk` attributes are rearranged to ensure correct ordering of vector components (except for computes and fixes - these have to be given in the right order) and duplicate entries are removed.
The VTK format uses a single snapshot of the system per file, thus a wildcard "*" must be included in the filename, as discussed below. Otherwise the dump files will get overwritten with the new snapshot each time.

Dumps are performed on timesteps that are a multiple of N (including timestep 0) and on the last timestep of a minimization if the minimization converges. Note that this means a dump will not be performed on the initial timestep after the dump command is invoked, if the current timestep is not a multiple of N. This behavior can be changed via the `dump_modify first` command, which can also be useful if the dump command is invoked after a minimization ended on an arbitrary timestep. N can be changed between runs by using the `dump_modify every` command. The `dump_modify every` command also allows a variable to be used to determine the sequence of timesteps on which dump files are written. In this mode a dump on the first timestep of a run will also not be written unless the `dump_modify first` command is used.

Dump filenames can contain two wildcard characters. If a "*" character appears in the filename, then one file per snapshot is written and the "*" character is replaced with the timestep value. For example, tmp.dump*.vtk becomes tmp.dump0.vtk, tmp.dump10000.vtk, tmp.dump20000.vtk, etc. Note that the `dump_modify pad` command can be used to insure all timestep numbers are the same length (e.g. 00010), which can make it easier to read a series of dump files in order with some post-processing tools.

If a "%" character appears in the filename, then each of P processors writes a portion of the dump file, and the "%" character is replaced with the processor ID from 0 to P-1 preceded by an underscore character. For example, tmp.dump%.vtp becomes tmp.dump_0.vtp, tmp.dump_1.vtp, ... tmp.dump_P-1.vtp, etc. This creates smaller files and can be a fast mode of output on parallel machines that support parallel I/O for output.

By default, P = the number of processors meaning one file per processor, but P can be set to a smaller value via the `nfile` or `fileper` keywords of the `dump_modify` command. These options can be the most efficient way of writing out dump files when running on large numbers of processors.

For the legacy VTK format "%" is ignored and P = 1, i.e., only processor 0 does write files.

Note that using the "*" and "%" characters together can produce a large number of small dump files!

If `dump_modify binary` is used, the dump file (or files, if "*" or "%" is also used) is written in binary format. A binary dump file will be about the same size as a text version, but will typically write out much faster.

### 16.48.4 Restrictions

The `vtk` style does not support writing of gzipped dump files.

The `vtk` dump style is part of the VTK package. It is only enabled if LAMMPS was built with that package. See the `Build package` page for more info.

To use this dump style, you also must link to the VTK library. See the info in `lib/vtk/README` and insure the Makefile.lammps file in that directory is appropriate for your machine.

The `vtk` dump style supports neither buffering or custom format strings.
16.48.5 Related commands

dump, dump image, dump_modify, undump

16.48.6 Default

By default, files are written in ASCII format. If the file extension is not one of .vtk, .vtp or .vtu, the legacy VTK file format is used.

16.49 dynamical_matrix command

Accelerator Variants: dynamical_matrix/kk

16.49.1 Syntax

```
dynamical_matrix group-ID style gamma args keyword value ...
```

- group-ID = ID of group of atoms to displace
- style = regular or eskm
- gamma = finite different displacement length (distance units)
- one or more keyword/arg pairs may be appended

<table>
<thead>
<tr>
<th>keyword</th>
<th>file or binary</th>
</tr>
</thead>
<tbody>
<tr>
<td>file</td>
<td>name = name of output file for the dynamical matrix</td>
</tr>
<tr>
<td>binary</td>
<td>arg = yes or no or gzip</td>
</tr>
</tbody>
</table>

16.49.2 Examples

```
dynamical_matrix 1 regular 0.000001
```

```
dynamical_matrix 1 eskm 0.000001
```

```
dynamical_matrix 3 regular 0.00004 file dynmat.dat
```

```
dynamical_matrix 5 eskm 0.00000001 file dynamical.dat binary yes
```

16.49.3 Description

Calculate the dynamical matrix by finite difference of the selected group,

\[
D = \frac{\Phi^{\alpha\beta}_{ij}}{\sqrt{M_i M_j}}
\]

where D is the dynamical matrix and \( \Phi \) is the force constant matrix defined by

\[
\Phi^{\alpha\beta}_{ij} = \frac{\partial^2 U}{\partial x_{i\alpha} \partial x_{j\beta}}
\]

The output for the dynamical matrix is printed three elements at a time. The three elements are the three \( \beta \) elements for a respective \( i/\alpha/j \) combination. Each line is printed in order of \( j \) increasing first, \( \alpha \) second, and \( i \) last.
If the style eskm is selected, the dynamical matrix will be in units of inverse squared femtoseconds. These units will then conveniently leave frequencies in THz.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 16.49.4 Restrictions

The command collects an array of nine times the number of atoms in a group on every single MPI rank, so the memory requirements can be very significant for large systems.

This command is part of the PHONON package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

### 16.49.5 Related commands

`fix phonon`, `fix numdiff`,

`compute hma` uses an analytic formulation of the Hessian provided by a pair_style’s `Pair::single_hessian()` function, if implemented.

### 16.49.6 Default

The default settings are file = “dynmat.dyn”, binary = no

#### 16.50 echo command

**16.50.1 Syntax**

```
 echo style
```

- style = `none` or `screen` or `log` or `both`
16.50.2 Examples

```
echo both
echo log
```

16.50.3 Description

This command determines whether LAMMPS echoes each input script command to the screen and/or log file as it is read and processed. If an input script has errors, it can be useful to look at echoed output to see the last command processed.

The *command-line switch* `-echo` can be used in place of this command.

16.50.4 Restrictions

none

16.50.5 Related commands

none

16.50.6 Default

```
echo log
```

16.51 fix command

16.51.1 Syntax

```
fix ID group-ID style args
```

- ID = user-assigned name for the fix
- group-ID = ID of the group of atoms to apply the fix to
- style = one of a long list of possible style names (see below)
- args = arguments used by a particular style
16.51.2 Examples

```plaintext
fix 1 all nve
fix 3 all nvt temp 300.0 300.0 0.01
fix mine top setforce 0.0 NULL 0.0
```

16.51.3 Description

Set a fix that will be applied to a group of atoms. In LAMMPS, a “fix” is any operation that is applied to the system during timestepping or minimization. Examples include updating of atom positions and velocities due to time integration, controlling temperature, applying constraint forces to atoms, enforcing boundary conditions, computing diagnostics, etc. There are hundreds of fixes defined in LAMMPS and new ones can be added; see the Modify page for details.

Fixes perform their operations at different stages of the timestep. If 2 or more fixes operate at the same stage of the timestep, they are invoked in the order they were specified in the input script.

The ID of a fix can only contain alphanumeric characters and underscores.

Fixes can be deleted with the `unfix` command.

Note: The `unfix` command is the only way to turn off a fix; simply specifying a new fix with a similar style will not turn off the first one. This is especially important to realize for integration fixes. For example, using a `fix nve` command for a second run after using a `fix nvt` command for the first run, will not cancel out the NVT time integration invoked by the “fix nvt” command. Thus two time integrators would be in place!

If you specify a new fix with the same ID and style as an existing fix, the old fix is deleted and the new one is created (presumably with new settings). This is the same as if an “unfix” command were first performed on the old fix, except that the new fix is kept in the same order relative to the existing fixes as the old one originally was. Note that this operation also wipes out any additional changes made to the old fix via the `fix_modify` command.

The `fix modify` command allows settings for some fixes to be reset. See the page for individual fixes for details.

Some fixes store an internal “state” which is written to binary restart files via the `restart` or `write_restart` commands. This allows the fix to continue on with its calculations in a restarted simulation. See the `read_restart` command for info on how to re-specify a fix in an input script that reads a restart file. See the doc pages for individual fixes for info on which ones can be restarted.

Some fixes calculate one of three styles of quantities: global, per-atom, or local, which can be used by other commands or output as described below. A global quantity is one or more system-wide values, e.g. the energy of a wall interacting with particles. A per-atom quantity is one or more values per atom, e.g. the displacement vector for each atom since time 0. Per-atom values are set to 0.0 for atoms not in the specified fix group. Local quantities are calculated by each processor based on the atoms it owns, but there may be zero or more per atoms.

Note that a single fix can produce either global or per-atom or local quantities (or none at all), but not both global and per-atom. It can produce local quantities in tandem with global or per-atom quantities. The fix page will explain.

Global, per-atom, and local quantities each come in three kinds: a single scalar value, a vector of values, or a 2d array of values. The doc page for each fix describes the style and kind of values it produces, e.g. a per-atom vector. Some fixes produce more than one kind of a single style, e.g. a global scalar and a global vector.

When a fix quantity is accessed, as in many of the output commands discussed below, it can be referenced via the following bracket notation, where ID is the ID of the fix:
In other words, using one bracket reduces the dimension of the quantity once (vector -> scalar, array -> vector). Using two brackets reduces the dimension twice (array -> scalar). Thus a command that uses scalar fix values as input can also process elements of a vector or array.

Note that commands and variables which use fix quantities typically do not allow for all kinds, e.g. a command may require a vector of values, not a scalar. This means there is no ambiguity about referring to a fix quantity as f_ID even if it produces, for example, both a scalar and vector. The doc pages for various commands explain the details.

In LAMMPS, the values generated by a fix can be used in several ways:

- Global values can be output via the `thermo_style custom` or `fix ave/time` command. Or the values can be referenced in a `variable equal` or `variable atom` command.
- Per-atom values can be output via the `dump custom` command. Or they can be time-averaged via the `fix ave/atom` command or reduced by the `compute reduce` command. Or the per-atom values can be referenced in an `atom-style variable`.
- Local values can be reduced by the `compute reduce` command, or histogrammed by the `fix ave/histo` command.

See the Howto output page for a summary of various LAMMPS output options, many of which involve fixes.

The results of fixes that calculate global quantities can be either “intensive” or “extensive” values. Intensive means the value is independent of the number of atoms in the simulation, e.g. temperature. Extensive means the value scales with the number of atoms in the simulation, e.g. total rotational kinetic energy. Thermodynamic output will normalize extensive values by the number of atoms in the system, depending on the “thermo modify norm” setting. It will not normalize intensive values. If a fix value is accessed in another way, e.g. by a `variable`, you may want to know whether it is an intensive or extensive value. See the page for individual fixes for further info.

Each fix style has its own page which describes its arguments and what it does, as listed below. Here is an alphabetic list of fix styles available in LAMMPS. They are also listed in more compact form on the Commands fix doc page.

There are also additional accelerated fix styles included in the LAMMPS distribution for faster performance on CPUs, GPUs, and KNLs. The individual style names on the Commands fix doc page are followed by one or more of (g,i,k,o,t) to indicate which accelerated styles exist.

- `accelerate/cos` - apply cosine-shaped acceleration to atoms
- `acks2/reaxff` - apply ACKS2 charge equilibration
- `adapt` - change a simulation parameter over time
- `adaptfep` - enhanced version of fix adapt
- `addforce` - add a force to each atom
- `addtorque` - add a torque to a group of atoms
- `append/atoms` - append atoms to a running simulation
- `atc` - initiates a coupled MD/FE simulation
- `atom/swap` - Monte Carlo atom type swapping
- `ave/atom` - compute per-atom time-averaged quantities
- `ave/chunk` - compute per-chunk time-averaged quantities
• **ave/correlate** - compute/output time correlations
• **ave/correlate/long** -
• **ave/histo** - compute/output time-averaged histograms
• **ave/histo/weight** - weighted version of fix ave/histo
• **ave/time** - compute/output global time-averaged quantities
• **aveforce** - add an averaged force to each atom
• **balance** - perform dynamic load-balancing
• **brownian** - overdamped translational brownian motion
• **brownian/asphere** - overdamped translational and rotational brownian motion for ellipsoids
• **brownian/sphere** - overdamped translational and rotational brownian motion for spheres
• **bos** - NPT style time integration with pressure correction
• **bond/break** - break bonds on the fly
• **bond/create** - create bonds on the fly
• **bond/create/angle** - create bonds on the fly with angle constraints
• **bond/react** - apply topology changes to model reactions
• **bond/swap** - Monte Carlo bond swapping
• **box/relax** - relax box size during energy minimization
• **charge/regulation** - Monte Carlo sampling of charge regulation
• **cmap** - enables CMAP cross-terms of the CHARMM force field
• **colvars** - interface to the collective variables “Colvars” library
• **controller** - apply control loop feedback mechanism
• **damping/cundall** - Cundall non-viscous damping for granular simulations
• **deform** - change the simulation box size/shape
• **deposit** - add new atoms above a surface
• **dpd/energy** - constant energy dissipative particle dynamics
• **drag** - drag atoms towards a defined coordinate
• **drude** - part of Drude oscillator polarization model
• **drude/transform/direct** - part of Drude oscillator polarization model
• **drude/transform/inverse** - part of Drude oscillator polarization model
• **dt/reset** - reset the timestep based on velocity, forces
• **edpd/source** - add heat source to eDPD simulations
• **efield** - impose electric field on system
• **ehex** - enhanced heat exchange algorithm
• **electrode/conp** - impose electric potential
• **electrode/conq** - impose total electric charge
• **electrode/thermo** - apply thermo-potentiostat
- `electron/stopping` - electronic stopping power as a friction force
- `electron/stopping/fit` - electronic stopping power as a friction force
- `enforce2d` - zero out z-dimension velocity and force
- `eos/cv`
- `eos/table`
- `eos/table/rx`
- `evaporate` - remove atoms from simulation periodically
- `external` - callback to an external driver program
- `fli` - apply a Fast-Forward Langevin equation thermostat
- `filter/corotate` - implement corotation filter to allow larger timesteps with r-RESPA
- `flow/gauss` - Gaussian dynamics for constant mass flux
- `freeze` - freeze atoms in a granular simulation
- `gcme` - grand canonical insertions/deletions
- `gld` - generalized Langevin dynamics integrator
- `gle` - generalized Langevin equation thermostat
- `gravity` - add gravity to atoms in a granular simulation
- `grem` - implements the generalized replica exchange method
- `halt` - terminate a dynamics run or minimization
- `heat` - add/subtract momentum-conserving heat
- `hyper/global` - global hyperdynamics
- `hyper/local` - local hyperdynamics
- `imd` - implements the “Interactive MD” (IMD) protocol
- `indent` - impose force due to an indenter
- `ipi` - enable LAMMPS to run as a client for i-PI path-integral simulations
- `langevin` - Langevin temperature control
- `langevin/drude` - Langevin temperature control of Drude oscillators
- `langevin/eff` - Langevin temperature control for the electron force field model
- `langevin/spin` - Langevin temperature control for a spin or spin-lattice system
- `latte` - wrapper on LATTE density-functional tight-binding code
- `lb/fluid` -
- `lb/momentum`
- `lb/viscous`
- `lineforce` - constrain atoms to move in a line
- `manifoldforce` - restrain atoms to a manifold during minimization
- `mdi/aimd` - LAMMPS operates as driver for ab initio MD (AIMD) via the MolSSI Driver Interface (MDI)
- `meso/move` - move mesoscopic SPH/SDPD particles in a prescribed fashion
• mol/swap - Monte Carlo atom type swapping with a molecule
• momentum - zero the linear and/or angular momentum of a group of atoms
• momentum/chunk - zero the linear and/or angular momentum of a chunk of atoms
• move - move atoms in a prescribed fashion
• mscg - apply MSCG method for force-matching to generate coarse grain models
• msst - multi-scale shock technique (MSST) integration
• mvv/dpd - DPD using the modified velocity-Verlet integration algorithm
• mvv/edpd - constant energy DPD using the modified velocity-Verlet algorithm
• mvv/tdpd - constant temperature DPD using the modified velocity-Verlet algorithm
• neb - nudged elastic band (NEB) spring forces
• neb/spin - nudged elastic band (NEB) spring forces for spins
• nph - constant NPH time integration via Nose/Hoover
• nph/asphere - NPH for aspherical particles
• nph/body - NPH for body particles
• nph/eff - NPH for nuclei and electrons in the electron force field model
• nph/sphere - NPH for spherical particles
• nphug - constant-stress Hugoniostat integration
• npt - constant NPT time integration via Nose/Hoover
• npt/asphere - NPT for aspherical particles
• npt/body - NPT for body particles
• npt/cauchy - NPT with Cauchy stress
• npt/eff - NPT for nuclei and electrons in the electron force field model
• npt/sphere - NPT for spherical particles
• npt/uef - NPT style time integration with diagonal flow
• numdiff - numerically approximate atomic forces using finite energy differences
• numdiff/virial - numerically approximate virial stress tensor using finite energy differences
• nve - constant NVE time integration
• nve/asphere - NVE for aspherical particles
• nve/asphere/noforce - NVE for aspherical particles without forces
• nve/awpmd - NVE for the Antisymmetrized Wave Packet Molecular Dynamics model
• nve/body - NVE for body particles
• nve/dot - rigid body constant energy time integrator for coarse grain models
• nve/dotc/langevin - Langevin style rigid body time integrator for coarse grain models
• nve/eff - NVE for nuclei and electrons in the electron force field model
• nve/limit - NVE with limited step length
• nve/line - NVE for line segments
- **nve/manifold/rattle** -
- **nve/noforce** - NVE without forces (v only)
- **nve/sphere** - NVE for spherical particles
- **nve/bpm/sphere** - NVE for spherical particles used in the BPM package
- **nve/spin** - NVE for a spin or spin-lattice system
- **nve/tri** - NVE for triangles
- **nvk** - constant kinetic energy time integration
- **nvt** - NVT time integration via Nose/Hoover
- **nvt/asphere** - NVT for aspherical particles
- **nvt/body** - NVT for body particles
- **nvt/eff** - NVE for nuclei and electrons in the electron force field model
- **nvt/manifold/rattle** -
- **nvt/sllod** - NVT for NEMD with SLLOD equations
- **nvt/sllod/eff** - NVT for NEMD with SLLOD equations for the electron force field model
- **nvt/sphere** - NVT for spherical particles
- **nvt/uef** - NVT style time integration with diagonal flow
- **oneway** - constrain particles on move in one direction
- **orient/bcc** - add grain boundary migration force for BCC
- **orient/fcc** - add grain boundary migration force for FCC
- **orient/eco** - add generalized grain boundary migration force
- **pafi** - constrained force averages on hyper-planes to compute free energies (PAFI)
- **phonon** - calculate dynamical matrix from MD simulations
- **pimd** - Feynman path integral molecular dynamics
- **planeforce** - constrain atoms to move in a plane
- **plumed** - wrapper on PLUMED free energy library
- **poems** - constrain clusters of atoms to move as coupled rigid bodies
- **polarize/bem/gmres** -
- **polarize/bem/icc** -
- **polarize/functional** -
- **pour** - pour new atoms/molecules into a granular simulation domain
- **precession/spin** -
- **press/berendsen** - pressure control by Berendsen barostat
- **print** - print text and variables during a simulation
- **propel/self** - model self-propelled particles
- **property/atom** - add customized per-atom values
- **python/invoke** - call a Python function during a simulation
- `python/move` - call a Python function during a simulation run
- `qbmsst` - quantum bath multi-scale shock technique time integrator
- `qeq/comb` - charge equilibration for COMB potential
- `qeq/dynamic` - charge equilibration via dynamic method
- `qeq/fire` - charge equilibration via FIRE minimizer
- `qeq/point` - charge equilibration via point method
- `qeq/reaxff` - charge equilibration for ReaxFF potential
- `qeq/shielded` - charge equilibration via shielded method
- `qeq/slater` - charge equilibration via Slater method
- `qmmm` - functionality to enable a quantum mechanics/molecular mechanics coupling
- `qt` - implement quantum thermal bath scheme
- `rattle` - RATTLE constraints on bonds and/or angles
- `reaxff/bonds` - write out ReaxFF bond information
- `reaxff/species` - write out ReaxFF molecule information
- `recenter` - constrain the center-of-mass position of a group of atoms
- `restrain` - constrain a bond, angle, dihedral
- `rhok` - add bias potential for long-range ordered systems
- `rigid` - constrain one or more clusters of atoms to move as a rigid body with NVE integration
- `rigid/meso` - constrain clusters of mesoscopic SPH/SDPD particles to move as a rigid body
- `rigid/nph` - constrain one or more clusters of atoms to move as a rigid body with NPH integration
- `rigid/nph/small` - constrain many small clusters of atoms to move as a rigid body with NPH integration
- `rigid/npt` - constrain one or more clusters of atoms to move as a rigid body with NPT integration
- `rigid/npt/small` - constrain many small clusters of atoms to move as a rigid body with NPT integration
- `rigid/nve` - constrain one or more clusters of atoms to move as a rigid body with alternate NVE integration
- `rigid/nve/small` - constrain many small clusters of atoms to move as a rigid body with alternate NVE integration
- `rigid/nvt` - constrain one or more clusters of atoms to move as a rigid body with NVT integration
- `rigid/nvt/small` - constrain many small clusters of atoms to move as a rigid body with NVT integration
- `rigid/small` - constrain many small clusters of atoms to move as a rigid body with NVE integration
- `rx` -
- `saed/vtk` -
- `setforce` - set the force on each atom
- `setforce/spin` - set magnetic precession vectors on each atom
- `shake` - SHAKE constraints on bonds and/or angles
- `shardlow` - integration of DPD equations of motion using the Shardlow splitting
- `smd` - applied a steered MD force to a group
- `smd/adjust_dt` -
- smd/integrate_tlsph
- smd/integrate_ulsph
- smd/move_tri_surf
- smd/setvel
- smd/wall_surface
- sph - time integration for SPH/DPDE particles
- sph/stationary
- spring - apply harmonic spring force to group of atoms
- spring/chunk - apply harmonic spring force to each chunk of atoms
- spring/rg - spring on radius of gyration of group of atoms
- spring/self - spring from each atom to its origin
- srd - stochastic rotation dynamics (SRD)
- store/force - store force on each atom
- store/state - store attributes for each atom
- tdpd/source
- temp/berendsen - temperature control by Berendsen thermostat
- temp/cslld - canonical sampling thermostat with Langevin dynamics
- temp/csvr - canonical sampling thermostat with Hamiltonian dynamics
- temp/rescale - temperature control by velocity rescaling
- temp/rescale/eff - temperature control by velocity rescaling in the electron force field model
- tfmc - perform force-bias Monte Carlo with time-stamped method
- tgnvt/drude - NVT time integration for Drude polarizable model via temperature-grouped Nose-Hoover
- tgnpt/drude - NPT time integration for Drude polarizable model via temperature-grouped Nose-Hoover
- thermal/conductivity - Muller-Plathe kinetic energy exchange for thermal conductivity calculation
- ti/spring
- tmd - guide a group of atoms to a new configuration
- ttm - two-temperature model for electronic/atomic coupling (replicated grid)
- ttm/grid - two-temperature model for electronic/atomic coupling (distributed grid)
- ttm/mod - enhanced two-temperature model with additional options
- tune/kspace - auto-tune KSpace parameters
- vector - accumulate a global vector every N timesteps
- viscosity - Muller-Plathe momentum exchange for viscosity calculation
- viscous - viscous damping for granular simulations
- viscous/sphere - viscous damping on angular velocity for granular simulations
- wall/body/polygon
- wall/body/polyhedron
• **wall/colloid** - Lennard-Jones wall interacting with finite-size particles
• **wall/ees** - wall for ellipsoidal particles
• **wall/gran** - frictional wall(s) for granular simulations
• **wall/gran/region** -
• **wall/harmonic** - harmonic spring wall
• **wall/lj1043** - Lennard-Jones 10-4-3 wall
• **wall/lj126** - Lennard-Jones 12-6 wall
• **wall/lj93** - Lennard-Jones 9-3 wall
• **wall/morse** - Morse potential wall
• **wall/piston** - moving reflective piston wall
• **wall/reflect** - reflecting wall(s)
• **wall/reflect/stochastic** - reflecting wall(s) with finite temperature
• **wall/region** - use region surface as wall
• **wall/region/ees** - use region surface as wall for ellipsoidal particles
• **wall/srd** - slip/no-slip wall for SRD particles
• **widom** - Widom insertions of atoms or molecules

### 16.51.4 Restrictions

Some fix styles are part of specific packages. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info. The doc pages for individual fixes tell if it is part of a package.

### 16.51.5 Related commands

unfix, fix_modify

### 16.51.6 Default

none

### 16.52 fix_modify command

#### 16.52.1 Syntax

```plaintext
fix_modify fix-ID keyword value ...
```

- fix-ID = ID of the fix to modify
- one or more keyword/value pairs may be appended
- keyword = bodyforces or colname or dynamic/dof or energy or press or respa or temp or virial
Bodyforces:

- **value**: early or late
  - early/late = compute rigid-body forces/torques early or late in the timestep

Column names:

- **values**: ID string
  - ID = integer from 1 to N, or integer from -1 to -N, where N = # of quantities being output
  - or a fix output property keyword or reference to compute, fix, property or variable.

Dynamic/DOF:

- **value**: yes or no
  - yes/no = do or do not re-compute the number of degrees of freedom (DOF) contributing to the temperature

Energy:

- **value**: compute ID that calculates a pressure

Respa:

- **value**: 1 to max respa level or 0 (for outermost level)

Temp:

- **value**: compute ID that calculates a temperature

Virial:

- **value**: compute ID that calculates a temperature

### 16.52.2 Examples

```plaintext
fix_modify 3 temp myTemp press myPress
fix_modify 1 energy yes
fix_modify tether respa 2
fix_modify ave colname c_tether_press Pressure colname 1 Temperature
```

### 16.52.3 Description

Modify one or more parameters of a previously defined fix. Only specific fix styles support specific parameters. See the doc pages for individual fix commands for info on which ones support which fix_modify parameters.

The **temp** keyword is used to determine how a fix computes temperature. The specified compute ID must have been previously defined by the user via the `compute` command and it must be a style of compute that calculates a temperature. All fixes that compute temperatures define their own compute by default, as described in their documentation. Thus this option allows the user to override the default method for computing T.

The **press** keyword is used to determine how a fix computes pressure. The specified compute ID must have been previously defined by the user via the `compute` command and it must be a style of compute that calculates a pressure. All fixes that compute pressures define their own compute by default, as described in their documentation. Thus this option allows the user to override the default method for computing P.

The **energy** keyword can be used with fixes that support it, which is explained at the bottom of their doc page. Energy **yes** will add a contribution to the potential energy of the system. More specifically, the fix’s global or per-atom energy is included in the calculation performed by the `compute pe` or `compute pe/atom` commands. The former is what is used the `thermo_style` command for output of any quantity that includes the global potential energy of the system. Note that the `compute pe` and `compute pe/atom` commands also have an option to include or exclude the contribution from fixes. For fixes that tally a global energy, it can also be printed with thermodynamic output by using the keyword f_ID in the thermo_style custom command, where ID is the fix-ID of the appropriate fix.

**Note:** If you are performing an energy minimization with one of these fixes and want the energy and forces it produces to be part of the optimization criteria, you must specify the **energy yes** setting.
Note: For most fixes that support the energy keyword, the default setting is no. For a few it is yes, when a user would expect that to be the case. The page of each fix gives the default.

The virial keyword can be used with fixes that support it, which is explained at the bottom of their doc page. Virial yes will add a contribution to the virial of the system. More specifically, the fix’s global or per-atom virial is included in the calculation performed by the compute pressure or compute stress/atom commands. The former is what is used the thermo_style command for output of any quantity that includes the global pressure of the system. Note that the compute pressure and compute stress/atom commands also have an option to include or exclude the contribution from fixes.

Note: If you are performing an energy minimization with box relaxation and one of these fixes and want the virial contribution of the fix to be part of the optimization criteria, you must specify the virial yes setting.

Note: For most fixes that support the virial keyword, the default setting is no. For a few it is yes, when a user would expect that to be the case. The page of each fix gives the default.

For fixes that set or modify forces, it may be possible to select at which r-RESPA level the fix operates via the respa keyword. The RESPA level at which the fix is active can be selected. This is a number ranging from 1 to the number of levels. If the RESPA level is larger than the current maximum, the outermost level will be used, which is also the default setting. This default can be restored using a value of 0 for the RESPA level. The affected fix has to be enabled to support this feature; if not, fix_modify will report an error. Active fixes with a custom RESPA level setting are reported with their specified level at the beginning of a r-RESPA run.

The dynamic/dof keyword determines whether the number of atoms N in the fix group and their associated degrees of freedom are re-computed each time a temperature is computed. Only fix styles that calculate their own internal temperature use this option. Currently this is only the fix rigid/nvt/small and fix rigid/npt/small commands for the purpose of thermostating rigid body translation and rotation. By default, N and their DOF are assumed to be constant. If you are adding atoms or molecules to the system (see the fix pour, fix deposit, and fix gcmc commands) or expect atoms or molecules to be lost (e.g. due to exiting the simulation box or via fix evaporate), then this option should be used to insure the temperature is correctly normalized.

Note: Other thermostating fixes, such as fix nvt, do not use the dynamic/dof keyword because they use a temperature compute to calculate temperature. See the compute_modify dynamic/dof command for a similar way to insure correct temperature normalization for those thermostats.

The bodyforces keyword determines whether the forces and torques acting on rigid bodies are computed early at the post-force stage of each timestep (right after per-atom forces have been computed and communicated among processors), or late at the final-integrate stage of each timestep (after any other fixes have finished their post-force tasks). Only the rigid-body integration fixes use this option, which includes fix rigid and fix rigid/small, and their variants, and also fix poems.

The default is late. If there are other fixes that add forces to individual atoms, then the rigid-body constraints will include these forces when time-integrating the rigid bodies. If early is specified, then new fixes can be written that use or modify the per-body force and torque, before time-integration of the rigid bodies occurs. Note however this has the side effect, that fixes such as fix addforce, fix setforce, fix spring, which add forces to individual atoms will have no effect on the motion of the rigid bodies if they are specified in the input script after the fix rigid command. LAMMPS will give a warning if that is the case.

The colname keyword can be used to change the default header keywords in output files of fix styles that support it: currently only fix ave/time is supported. The setting for ID string replaces the default text with the provided string.
ID can be a positive integer when it represents the column number counting from the left, a negative integer when it represents the column number from the right (i.e. -1 is the last column/keyword), or a custom fix output keyword (or compute, fix, property, or variable reference) and then it replaces the string for that specific keyword. The colname keyword can be used multiple times. If multiple colname settings refer to the same keyword, the last setting has precedence.

16.52.4 Restrictions

none

16.52.5 Related commands

fix, compute temp, compute pressure, thermo_style

16.52.6 Default

The option defaults are temp = ID defined by fix, press = ID defined by fix, energy = no, virial = different for each fix style, respa = 0, bodyforce = late.

16.53 group command

16.53.1 Syntax

group ID style args

- ID = user-defined name of the group
- style = delete or clear or empty or region or type or id or molecule or variable or include or subtract or union or intersect or dynamic or static
  delete = no args
  clear = no args
  empty = no args
  region args = region-ID
  type or id or molecule
    any entry in list can be a sequence formatted as A:B or A:B:C where
    A = starting index, B = ending index, 
    C = increment between indices, 1 if not specified
  args = logical value
    logical = "<" or "<=" or ">" or ">=" or "==" or "!="
    value = an atom type or atom ID or molecule ID (depending on style)
  args = logical value1 value2
    logical = "<>"
    value1,value2 = atom types or atom IDs or molecule IDs (depending on style)
  variable args = variable-name
  include args = molecule
    molecule = add atoms to group with same molecule ID as atoms already in group
  subtract args = two or more group IDs
  union args = one or more group IDs
intersect args = two or more group IDs
dynamic args = parent-ID keyword value ...
one or more keyword/value pairs may be appended
keyword = region or var or property or every
    region value = region-ID
    var value = name of variable
    property value = name of custom integer or floating point vector
    every value = N = update group every this many timesteps
static = no args

16.53.2 Examples

```
group edge region regstrip
group water type 3 4
group sub id 10 25 50
   group sub id 10 25 50 500:1000
   group sub id 100:10000:10
   group sub id <= 150
   group polyA molecule <> 50 250
   group hienergy variable eng
   group hienergy include molecule
   group boundary subtract all a2 a3
   group boundary union lower upper
   group boundary intersect upper flow
   group boundary delete
   group mine dynamic all region myRegion every 100
```

16.53.3 Description

Identify a collection of atoms as belonging to a group. The group ID can then be used in other commands such as `fix`,
`compute`, `dump`, or `velocity` to act on those atoms together.

If the group ID already exists, the group command adds the specified atoms to the group.

**Note:** By default groups are static, meaning the atoms are permanently assigned to the group. For example, if the `region` style is used to assign atoms to a group, the atoms will remain in the group even if they later move out of the region. As explained below, the `dynamic` style can be used to make a group dynamic so that a periodic determination is made as to which atoms are in the group. Since many LAMMPS commands operate on groups of atoms, you should think carefully about whether making a group dynamic makes sense for your model.

A group with the ID `all` is predefined. All atoms belong to this group. This group cannot be deleted, or made dynamic.
The `delete` style removes the named group and un-assigns all atoms that were assigned to that group. Since there is a restriction (see below) that no more than 32 groups can be defined at any time, the `delete` style allows you to remove groups that are no longer needed, so that more can be specified. You cannot delete a group if it has been used to define a current `fix` or `compute` or `dump`.

The `clear` style un-assigns all atoms that were assigned to that group. This may be dangerous to do during a simulation run, e.g. using the `run every` command if a fix or compute or other operation expects the atoms in the group to remain constant, but LAMMPS does not check for this.

The `empty` style creates an empty group, which is useful for commands like `fix gcmc` or with complex scripts that add atoms to a group.
The `region` style puts all atoms in the region volume into the group. Note that this is a static one-time assignment. The atoms remain assigned (or not assigned) to the group even if they later move out of the region volume.

The `type`, `id`, and `molecule` styles put all atoms with the specified atom types, atom IDs, or molecule IDs into the group. These 3 styles can use arguments specified in one of two formats.

The first format is a list of values (types or IDs). For example, the second command in the examples above puts all atoms of type 3 or 4 into the group named `water`. Each entry in the list can be a colon-separated sequence `A:B` or `A:B:C`, as in two of the examples above. A “sequence” generates a sequence of values (types or IDs), with an optional increment. The first example with `500:1000` has the default increment of 1 and would add all atom IDs from 500 to 1000 (inclusive) to the group sub, along with 10,25,50 since they also appear in the list of values. The second example with `100:10000:10` uses an increment of 10 and would thus would add atoms IDs 100,110,120, … 9990,10000 to the group sub.

The second format is a `logical` followed by one or two values (type or ID). The 7 valid logics are listed above. All the logics except `<>` take a single argument. The third example above adds all atoms with IDs from 1 to 150 to the group named `sub`. The logical `<>` means “between” and takes 2 arguments. The fourth example above adds all atoms belonging to molecules with IDs from 50 to 250 (inclusive) to the group named `polyA`.

The `variable` style evaluates a variable to determine which atoms to add to the group. It must be an `atom-style variable` previously defined in the input script. If the variable evaluates to a non-zero value for a particular atom, then that atom is added to the specified group.

Atom-style variables can specify formulas that include thermodynamic quantities, per-atom values such as atom coordinates, or per-atom quantities calculated by computes, fixes, or other variables. They can also include Boolean logic where 2 numeric values are compared to yield a 1 or 0 (effectively a true or false). Thus using the `variable` style, is a general way to flag specific atoms to include or exclude from a group.

For example, these lines define a variable “eatom” that calculates the potential energy of each atom and includes it in the group if its potential energy is above the threshold value -3.0.

```
compute 1 all pe/atom
compute 2 all reduce sum c_1
thermo_style custom step temp pe c_2
run 0
variable eatom atom "c_1 > -3.0"
group hienergy variable eatom
```

Note that these lines

```
compute 2 all reduce sum c_1
thermo_style custom step temp pe c_2
run 0
```

are necessary to insure that the “eatom” variable is current when the group command invokes it. Because the eatom variable computes the per-atom energy via the `pe/atom` compute, it will only be current if a run has been performed which evaluated pairwise energies, and the `pe/atom` compute was actually invoked during the run. Printing the thermodynamic info for compute 2 insures that this is the case, since it sums the `pe/atom` compute values (in the reduce compute) to output them to the screen. See the “Variable Accuracy” section of the `variable` page for more details on insuring that variables are current when they are evaluated between runs.

The `include` style with its arg `molecule` adds atoms to a group that have the same molecule ID as atoms already in the group. The molecule ID = 0 is ignored in this operation, since it is assumed to flag isolated atoms that are not part of molecules. An example of where this operation is useful is if the `region` style has been used previously to add atoms to a group that are within a geometric region. If molecules straddle the region boundary, then atoms outside the region that are part of molecules with atoms inside the region will not be in the group. Using the group command a second time with `include molecule` will add those atoms that are outside the region to the group.
Note: The \textit{include molecule} operation is relatively expensive in a parallel sense. This is because it requires communication of relevant molecule IDs between all the processors and each processor to loop over its atoms once per processor, to compare its atoms to the list of molecule IDs from every other processor. Hence it scales as N, rather than N/P as most of the group operations do, where N is the number of atoms, and P is the number of processors.

The \textit{subtract} style takes a list of two or more existing group names as arguments. All atoms that belong to the first group, but not to any of the other groups are added to the specified group.

The \textit{union} style takes a list of one or more existing group names as arguments. All atoms that belong to any of the listed groups are added to the specified group.

The \textit{intersect} style takes a list of two or more existing group names as arguments. Atoms that belong to every one of the listed groups are added to the specified group.

The \textit{dynamic} style flags an existing or new group as dynamic. This means atoms will be (re)assigned to the group periodically as a simulation runs. This is in contrast to static groups where atoms are permanently assigned to the group. The way the assignment occurs is as follows. Only atoms in the group specified as the parent group via the parent-ID are assigned to the dynamic group before the following conditions are applied.

If the \textit{region} keyword is used, atoms not in the specified region are removed from the dynamic group.

If the \textit{var} keyword is used, the variable name must be an atom-style or atomfile-style variable. The variable is evaluated and atoms whose per-atom values are 0.0, are removed from the dynamic group.

If the \textit{property} keyword is used, the name refers to a custom integer or floating point per-atom vector defined via the \texttt{fix property/atom} command. This means the values in the vector can be read as part of a data file with the \texttt{read_data} command or specified with the \texttt{set} command. Or accessed and changed via the \textit{library interface to LAMMPS}, or by styles you add to LAMMPS (pair, fix, compute, etc) which access the custom vector and modify its values. Which means the values can be modified between or during simulations. Atoms whose values in the custom vector are zero are removed from the dynamic group. Note that the name of the custom per-atom vector is specified just as \textit{name}, not as \texttt{i\_name} or \texttt{d\_name} as it is for other commands that use different kinds of custom atom vectors or arrays as arguments.

The assignment of atoms to a dynamic group is done at the beginning of each run and on every timestep that is a multiple of \texttt{N}, which is the argument for the \texttt{every} keyword (\texttt{N = 1} is the default). For an energy minimization, via the \texttt{minimize} command, an assignment is made at the beginning of the minimization, but not during the iterations of the minimizer.

The point in the timestep at which atoms are assigned to a dynamic group is after interatomic forces have been computed, but before any fixes which alter forces or otherwise update the system have been invoked. This means that atom positions have been updated, neighbor lists and ghost atoms are current, and both intermolecular and intramolecular forces have been calculated based on the new coordinates. Thus the region criterion, if applied, should be accurate. Also, any computes invoked by an atom-style variable should use updated information for that timestep, e.g. potential energy/atom or coordination number/atom. Similarly, fixes or computes which are invoked after that point in the timestep, should operate on the new group of atoms.

Note: If the \textit{region} keyword is used to determine what atoms are in the dynamic group, atoms can move outside of the simulation box between reneighboring events. Thus if you want to include all atoms on the left side of the simulation box, you probably want to set the left boundary of the region to be outside the simulation box by some reasonable amount (e.g. up to the cutoff of the potential), else they may be excluded from the dynamic region.

Here is an example of using a dynamic group to shrink the set of atoms being integrated by using a spherical region with a variable radius (shrinking from 18 to 5 over the course of the run). This could be used to model a quench of the system, freezing atoms outside the shrinking sphere, then converting the remaining atoms to a static group and running further.
```plaintext
variable nsteps equal 5000
variable rad equal 18-(step/v_nsteps)*(18-5)
region ss sphere 20 20 0 v_rad
group mobile dynamic all region ss
fix 1 mobile nve
run ${nsteps}
group mobile static
run ${nsteps}
```

Note: All fixes and computes take a group ID as an argument, but they do not all allow for use of a dynamic group. If you get an error message that this is not allowed, but feel that it should be for the fix or compute in question, then please post your reasoning to the LAMMPS forum at MatSci and we can look into changing it. The same applies if you come across inconsistent behavior when dynamic groups are allowed.

The *static* style removes the setting for a dynamic group, converting it to a static group (the default). The atoms in the static group are those currently in the dynamic group.

### 16.53.4 Restrictions

There can be no more than 32 groups defined at one time, including “all”.
The parent group of a dynamic group cannot itself be a dynamic group.

### 16.53.5 Related commands

*dump, fix, region, velocity*

### 16.53.6 Default

All atoms belong to the “all” group.

### 16.54 group2ndx command

### 16.55 ndx2group command

### 16.55.1 Syntax

```
group2ndx file group-ID ...
ndx2group file group-ID ...
```

- file = name of index file to write out or read in
- zero or more group IDs may be appended

16.55.3 Description

Write or read a Gromacs style index file in text format that associates atom IDs with the corresponding group definitions. This index file can be used with in combination with Gromacs analysis tools or to import group definitions into the `fix colvars` input file. It can also be used to save and restore group definitions for static groups.

The `group2ndx` command will write group definitions to an index file. Without specifying any group IDs, all groups will be written to the index file. When specifying group IDs, only those groups will be written to the index file. In order to follow the Gromacs conventions, the group `all` will be renamed to `System` in the index file.

The `ndx2group` command will create or update group definitions from those stored in an index file. Without specifying any group IDs, all groups except `System` will be read from the index file and the corresponding groups recreated. If a group of the same name already exists, it will be completely reset. When specifying group IDs, those groups, if present, will be read from the index file and restored.

16.55.4 Restrictions

This command requires that atoms have atom IDs, since this is the information that is written to the index file.

These commands are part of the COLVARS package. They are only enabled if LAMMPS was built with that package. See the `Build package` page for more info.

16.55.5 Related commands

none

16.56 hyper command

16.56.1 Syntax

```
hyper N Nevent fix-ID compute-ID keyword values ...
```

- `N` = # of timesteps to run
- `Nevent` = check for events every this many steps
- `fix-ID` = ID of a fix that applies a global or local bias potential, can be NULL

---

782 Chapter 16. Commands
• compute-ID = ID of a compute that identifies when an event has occurred
• zero or more keyword/value pairs may be appended
• keyword = \textit{min} or \textit{dump} or \textit{rebond}

\textit{min} values = etol ftol maxiter maxeval
\textit{etol} = stopping tolerance for energy, used in quenching
\textit{ftol} = stopping tolerance for force, used in quenching
\textit{maxiter} = max iterations of minimize, used in quenching
\textit{maxeval} = max number of force/energy evaluations, used in quenching

\textit{dump} value = dump-ID
\textit{dump-ID} = ID of dump to trigger whenever an event takes place

\textit{rebond} value = Nrebond
\textit{Nrebond} = frequency at which to reset bonds, even if no event has occurred

\subsection*{16.56.2 Examples}

\begin{verbatim}
compute event all event/displace 1.0
fix HG mobile hyper/global 3.0 0.3 0.4 800.0
hyper 5000 100 HG event min 1.0e-6 1.0e-6 100 100 dump 1 dump 5
\end{verbatim}

\subsection*{16.56.3 Description}

Run a bond-boost hyperdynamics (HD) simulation where time is accelerated by application of a bias potential to one or more pairs of nearby atoms in the system. This command can be used to run both global and local hyperdynamics. In global HD a single bond within the system is biased on each timestep. In local HD multiple bonds (separated by a sufficient distance) can be biased simultaneously at each timestep. In the bond-boost hyperdynamics context, a “bond” is not a covalent bond between a pair of atoms in a molecule. Rather it is simply a pair of nearby atoms as discussed below.

Both global and local HD are described in \cite{Voter2013} by Art Voter and collaborators. Similar to parallel replica dynamics (PRD), global and local HD are methods for performing accelerated dynamics that are suitable for infrequent-event systems that obey first-order kinetics. A good overview of accelerated dynamics methods (AMD) for such systems is given in \cite{Voter2002} from the same group. To quote from the review paper: “The dynamical evolution is characterized by vibrational excursions within a potential basin, punctuated by occasional transitions between basins. The transition probability is characterized by \( p(t) = k \exp(-kt) \) where \( k \) is the rate constant.”

Both HD and PRD produce a time-accurate trajectory that effectively extends the timescale over which a system can be simulated, but they do it differently. HD uses a single replica of the system and accelerates time by biasing the interaction potential in a manner such that each timestep is effectively longer. PRD creates \( N_r \) replicas of the system and runs dynamics on each independently with a normal unbiased potential until an event occurs in one of the replicas. The time between events is reduced by a factor of \( N_r \) replicas. For both methods, per CPU second, more physical time elapses and more events occur. See the \textit{prd} page for more info about PRD.

An HD run has several stages, which are repeated each time an event occurs, as explained below. The logic for an HD run is as follows:

\begin{verbatim}
quench
create initial list of bonds
while (time remains):
  run dynamics for \( N \) event steps
  quench
\end{verbatim}

(continues on next page)
The list of bonds is the list of atom pairs of atoms that are within a short cutoff distance of each other after the system energy is minimized (quenched). This list is created and reset by a `fix hyper/global` or `fix hyper/local` command specified as `fix-ID`. At every dynamics timestep, the same fix selects one of more bonds to apply a bias potential to.

**Note:** The style of fix associated with the specified `fix-ID` determines whether you are running the global versus local hyperdynamics algorithm.

Dynamics (with the bias potential) is run continuously, stopping every `Nevent` steps to check if a transition event has occurred. The specified $N$ for total steps must be a multiple of `Nevent`. check is performed by quenching the system and comparing the resulting atom coordinates to the coordinates from the previous basin.

A quench is an energy minimization and is performed by whichever algorithm has been defined by the `min_style` command. Minimization parameters may be set via the `min_modify` command and by the `min` keyword of the hyper command. The latter are the settings that would be used with the `minimize` command. Note that typically, you do not need to perform a highly-converged minimization to detect a transition event, though you may need to in order to prevent a set of atoms in the system from relaxing to a saddle point.

The event check is performed by a compute with the specified `compute-ID`. Currently there is only one compute that works with the hyper command, which is the `compute event/displace` command. Other event-checking computes may be added. `Compute event/displace` checks whether any atom in the compute group has moved further than a specified threshold distance. If so, an event has occurred.

If this happens, the list of bonds is reset, since some bond pairs are likely now too far apart, and new pairs are likely close enough to be considered a bond. The pre-quenched state of the system (coordinates and velocities) is restored, and dynamics continue.

At the end of the hyper run, a variety of statistics are output to the screen and logfile. These include info relevant to both global and local hyperdynamics, such as the number of events and the elapsed hyper time (accelerated time). And it includes info specific to one or the other, depending on which style of fix was specified by `fix-ID`.

The optional keywords operate as follows.

As explained above, the `min` keyword can be used to specify parameters for the quench. Their meaning is the same as for the `minimize` command.

The `dump` keyword can be used to trigger a specific dump command with the specified `dump-ID` to output a snapshot each time an event is detected. It can be specified multiple times with different `dump-ID` values, as in the example above. These snapshots will be for the quenched state of the system on a timestep that is a multiple of `Nevent`, i.e. a timestep after the event has occurred. Note that any dump command in the input script will also output snapshots at whatever timestep interval it defines via its $N$ argument; see the `dump` command for details. This means if you only want a particular dump to output snapshots when events are detected, you should specify its $N$ as a value larger than the length of the hyperdynamics run.

As in the code logic above, the bond list is normally only reset when an event occurs. The `rebond` keyword will force a reset of the bond list every `Nrebond` steps, even if an event has not occurred. `Nrebond` must be a multiple of `Nevent`. This can be useful to check if more frequent resets alter event statistics, perhaps because the parameters chosen for defining what is a bond and what is an event are producing bad dynamics in the presence of the bias potential.
16.56.4 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the Build package doc page for more info.

16.56.5 Related commands

fix hyper/global, fix hyper/local, compute event/displace, prd

16.56.6 Default

The option defaults are min = 0.1 0.1 40 50 and time = steps.

16.57 if command

16.57.1 Syntax

```plaintext
if boolean then t1 t2 ... elif boolean f1 f2 ... elif boolean f1 f2 ... else e1 e2 ...
```

- boolean = a Boolean expression evaluated as TRUE or FALSE (see below)
- then = required word
- t1,t2,...,tN = one or more LAMMPS commands to execute if condition is met, each enclosed in quotes
- elif = optional word, can appear multiple times
- f1,f2,...,fN = one or more LAMMPS commands to execute if elif condition is met, each enclosed in quotes (optional arguments)
- else = optional argument
- e1,e2,...,eN = one or more LAMMPS commands to execute if no condition is met, each enclosed in quotes (optional arguments)

16.57.2 Examples

```plaintext
if "${steps} > 1000" then quit
if "${myString} == a10" then quit
if "$x <= $y" then "print X is smaller = $x" else "print Y is smaller = $y"
if "(${eng} > 0.0) || ($n < 1000)" then &
    "timestep 0.005" &
elif $n<10000 &
    "timestep 0.01" &
extelse &
    "timestep 0.02" &
```

(continues on next page)
if "$\{\text{eng} \} > \{\text{eng\_previous}\}" then "jump file1" else "jump file2"

### 16.57.3 Description

This command provides an if-then-else capability within an input script. A Boolean expression is evaluated and the result is TRUE or FALSE. Note that as in the examples above, the expression can contain variables, as defined by the `variable` command, which will be evaluated as part of the expression. Thus a user-defined formula that reflects the current state of the simulation can be used to issue one or more new commands.

If the result of the Boolean expression is TRUE, then one or more commands ($t_1$, $t_2$, $t_N$) are executed. If it is FALSE, then the associated commands for the else keyword, namely ($e_1$, $e_2$, $e_N$), are executed. The elif and else keywords and their associated commands are optional. If they are not specified and the initial Boolean expression is FALSE, then no commands are executed.

The syntax for Boolean expressions is described below.

Each command ($t_1$, $f_1$, $e_1$, etc) can be any valid LAMMPS input script command. If the command is more than one word, it must be enclosed in quotes, so it will be treated as a single argument, as in the examples above.

#### Note:

If a command itself requires a quoted argument (e.g. a `print` command), then double and single quotes can be used and nested in the usual manner, as in the examples above and below. The `Commands parse` page has more details on using quotes in arguments. Only one level of nesting is allowed, but that should be sufficient for most use cases.

Note that by using the line continuation character “&”, the if command can be spread across many lines, though it is still a single command:

```
if "$a < \text{b}" then &
  "print 'Minimum value = \text{a}'" &
  "run 1000" &
else &
  "print 'Minimum value = \text{b}'" &
  "minimize 0.001 0.001 1000 10000"
```

Note that if one of the commands to execute is `quit`, as in the first example above, then executing the command will cause LAMMPS to halt.

Note that by jumping to a label in the same input script, the if command can be used to break out of a loop. See the `variable delete` command for info on how to delete the associated loop variable, so that it can be re-used later in the input script.

Here is an example of a loop which checks every 1000 steps if the system temperature has reached a certain value, and if so, breaks out of the loop to finish the run. Note that any variable could be checked, so long as it is current on the timestep when the run completes. As explained on the `variable` doc page, this can be insured by including the variable in thermodynamic output.

```
variable \text{myTemp} \text{equal} temp
label loop
variable \text{a} \text{loop} 1000
run 1000
if "$\{\text{myTemp}\} < 300.0" then "jump \text{SELF break}"
```

(continues on next page)
Here is an example of a double loop which uses the if and jump commands to break out of the inner loop when a condition is met, then continues iterating through the outer loop.

```
next a
jump SELF loop
label break
print "ALL DONE"
```

The Boolean expressions for the if and elif keywords have a C-like syntax. Note that each expression is a single argument within the if command. Thus if you want to include spaces in the expression for clarity, you must enclose the entire expression in quotes.

An expression is built out of numbers (which start with a digit or period or minus sign) or strings (which start with a letter and can contain alphanumeric characters, underscores, or forward slashes):

```
0.2, 100, 1.0e20, -15.4, ...
InP, myString, a123, ab_23_cd, lj/cut, ...
```

and Boolean operators:

```
```

Each A and B is a number or string or a variable reference like $a or ${abc}, or A or B can be another Boolean expression.

If a variable is used it can produce a number when evaluated, like an equal-style variable. Or it can produce a string, like an index-style variable. For an individual Boolean operator, A and B must both be numbers or must both be strings. You cannot compare a number to a string.

Expressions are evaluated left to right and have the usual C-style precedence: the unary logical NOT operator “!” has the highest precedence, the 4 relational operators “<”, “<=”, “>”, and “>=” are next; the two remaining relational operators “==” and “!=” are next; then the logical AND operator “&&”; and finally the logical OR operator “||” and logical XOR (exclusive or) operator “^” have the lowest precedence. Parenthesis can be used to group one or more portions of an expression and/or enforce a different order of evaluation than what would occur with the default precedence.

When the 6 relational operators (first 6 in list above) compare 2 numbers, they return either a 1.0 or 0.0 depending on whether the relationship between A and B is TRUE or FALSE. When the 6 relational operators compare 2 strings, they also return a 1.0 or 0.0 for TRUE or FALSE, but the comparison is done by the C function strcmp().

When the 3 logical operators (last 3 in list above) compare 2 numbers, they also return either a 1.0 or 0.0 depending on whether the relationship between A and B is TRUE or FALSE (or just A). The logical AND operator will return 1.0 if
both its arguments are non-zero, else it returns 0.0. The logical OR operator will return 1.0 if either of its arguments
is non-zero, else it returns 0.0. The logical XOR operator will return 1.0 if one of its arguments is zero and the other
non-zero, else it returns 0.0. The logical NOT operator returns 1.0 if its argument is 0.0, else it returns 0.0. The 3
logical operators can only be used to operate on numbers, not on strings.

The overall Boolean expression produces a TRUE result if the result is non-zero. If the result is zero, the expression
result is FALSE.

16.57.4 Restrictions

none

16.57.5 Related commands

variable, print

16.57.6 Default

none

16.58 improper_coeff command

16.58.1 Syntax

\texttt{improper\_coeff} N args

- N = improper type (see asterisk form below)
- args = coefficients for one or more improper types

16.58.2 Examples

\texttt{improper\_coeff} 1 300.0 0.0
\texttt{improper\_coeff} * 80.2 -1 2
\texttt{improper\_coeff} *4 80.2 -1 2

16.58.3 Description

Specify the improper force field coefficients for one or more improper types. The number and meaning of the coef-
ficients depends on the improper style. Improper coefficients can also be set in the data file read by the \texttt{read\_data}
command or in a restart file.

N can be specified in one of two ways. An explicit numeric value can be used, as in the first example above. Or a
wild-card asterisk can be used to set the coefficients for multiple improper types. This takes the form “*" or “*n" or
“n*" or “m*n”. If N = the number of improper types, then an asterisk with no numeric values means all types from 1 to
N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive).
A middle asterisk means all types from m to n (inclusive).
Note that using an improper_coeff command can override a previous setting for the same improper type. For example, these commands set the coeffs for all improper types, then overwrite the coeffs for just improper type 2:

```
  improper_coeff * 300.0 0.0
  improper_coeff 2 50.0 0.0
```

A line in a data file that specifies improper coefficients uses the exact same format as the arguments of the improper_coeff command in an input script, except that wild-card asterisks should not be used since coefficients for all N types must be listed in the file. For example, under the “Improper Coeffs” section of a data file, the line that corresponds to the first example above would be listed as

```
  1 300.0 0.0
```

The improper_style class2 is an exception to this rule, in that an additional argument is used in the input script to allow specification of the cross-term coefficients. See its doc page for details.

The list of all improper styles defined in LAMMPS is given on the improper_style doc page. They are also listed in more compact form on the Commands improper doc page. On either of those pages, click on the style to display the formula it computes and its coefficients as specified by the associated improper_coeff command.

### 16.58.4 Restrictions

This command must come after the simulation box is defined by a read_data, read_restart, or create_box command. An improper style must be defined before any improper coefficients are set, either in the input script or in a data file.

### 16.58.5 Related commands

improper_style

### 16.58.6 Default

none

### 16.59 improper_style command

#### 16.59.1 Syntax

```
improper_style style
```

- style = none or hybrid or class2 or cvff or harmonic
16.59.2 Examples

improper_style harmonic
improper_style cvff
improper_style hybrid cvff harmonic

16.59.3 Description

Set the formula(s) LAMMPS uses to compute improper interactions between quadruplets of atoms, which remain in force for the duration of the simulation. The list of improper quadruplets is read in by a read_data or read_restart command from a data or restart file. Note that the ordering of the 4 atoms in an improper quadruplet determines the definition of the improper angle used in the formula for each style. See the doc pages of individual styles for details.

Hybrid models where impropers are computed using different improper potentials can be setup using the hybrid improper style.

The coefficients associated with an improper style can be specified in a data or restart file or via the improper_coeff command.

All improper potentials store their coefficient data in binary restart files which means improper_style and improper_coeff commands do not need to be re-specified in an input script that restarts a simulation. See the read_restart command for details on how to do this. The one exception is that improper_style hybrid only stores the list of sub-styles in the restart file; improper coefficients need to be re-specified.

Note: When both an improper and pair style is defined, the special_bonds command often needs to be used to turn off (or weight) the pairwise interaction that would otherwise exist between a group of 4 bonded atoms.

Here is an alphabetic list of improper styles defined in LAMMPS. Click on the style to display the formula it computes and coefficients specified by the associated improper_coeff command.

Click on the style to display the formula it computes, any additional arguments specified in the improper_style command, and coefficients specified by the associated improper_coeff command.

There are also additional accelerated pair styles included in the LAMMPS distribution for faster performance on CPUs, GPUs, and KNLs. The individual style names on the Commands improper page are followed by one or more of (g,i,k,o,t) to indicate which accelerated styles exist.

- none - turn off improper interactions
- zero - topology but no interactions
- hybrid - define multiple styles of improper interactions
- class2 - COMPASS (class 2) improper
- cossq - improper with a cosine squared term
- cvff - CVFF improper
- distance - improper based on distance between atom planes
- distharm - improper that is harmonic in the out-of-plane distance
- fourier - improper with multiple cosine terms
- harmonic - harmonic improper
- inversion/harmonic - harmonic improper with Wilson-Decius out-of-plane definition
16.59.4 Restrictions

Improper styles can only be set for atom_style choices that allow impropers to be defined.

Most improper styles are part of the MOLECULE package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info. The doc pages for individual improper potentials tell if it is part of a package.

16.61 info command

16.61.1 Syntax

```
info args
```

- `args` = one or more of the following keywords: out, all, system, memory, communication, computes, dumps, fixes, groups, regions, variables, coeffs, styles, time, accelerator, or configuration
- `out` values = screen, log, append filename, overwrite filename
- `styles` values = all, angle, atom, bond, compute, command, dump, dihedral, fix, improper, integrate, kspace, minimize, pair, region

16.61.2 Examples

```
info system
info groups computes variables
info all out log
info all out append info.txt
info styles all
info styles atom
```

16.61.3 Description

Print out information about the current internal state of the running LAMMPS process. This can be helpful when debugging or validating complex input scripts. Several output categories are available and one or more output category may be requested.

The `out` flag controls where the output is sent. It can only be sent to one target. By default this is the screen, if it is active. The `log` argument selects the log file instead. With the `append` and `overwrite` option, followed by a filename, the output is written to that file, which is either appended to or overwritten, respectively.

The `all` flag activates printing all categories listed below.

The `configuration` category prints some information about the LAMMPS version as well as architecture and OS it is run on.
The `memory` category prints some information about the current memory allocation of MPI rank 0 (this the amount of dynamically allocated memory reported by LAMMPS classes). Where supported, also some OS specific information about the size of the reserved memory pool size (this is where malloc() and the new operator request memory from) and the maximum resident set size is reported (this is the maximum amount of physical memory occupied so far).

The `system` category prints a general system overview listing. This includes the unit style, atom style, number of atoms, bonds, angles, dihedrals, and impropers and the number of the respective types, box dimensions and properties, force computing styles and more.

The `communication` category prints a variety of information about communication and parallelization: the MPI library version level, the number of MPI ranks and OpenMP threads, the communication style and layout, the processor grid dimensions, ghost atom communication mode, cutoff, and related settings.

The `computes` category prints a list of all currently defined computes, their IDs and styles and groups they operate on.

The `dumps` category prints a list of all currently active dumps, their IDs, styles, filenames, groups, and dump frequencies.

The `fixes` category prints a list of all currently defined fixes, their IDs and styles and groups they operate on.

The `groups` category prints a list of all currently defined groups.

The `regions` category prints a list of all currently defined regions, their IDs and styles and whether “inside” or “outside” atoms are selected.

The `variables` category prints a list of all currently defined variables, their names, styles, definition and last computed value, if available.

The `coeffs` category prints a list for each defined force style (pair, bond, angle, dihedral, improper) indicating which of the corresponding coefficients have been set. This can be very helpful to debug error messages like “All pair coeffs are not set”.

The `accelerator` category prints out information about compile time settings of included accelerator support for the GPU, KOKKOS, INTEL, and OPENMP packages.

The `styles` category prints the list of styles available in the current LAMMPS binary. It supports one of the following options to control which category of styles is printed out:

- all
- angle
- atom
- bond
- compute
- command
- dump
- dihedral
- fix
- improper
- integrate
- kspace
- minimize
- pair
- region
The time category prints the accumulated CPU and wall time for the process that writes output (usually MPI rank 0).

### 16.61.4 Restrictions

none

### 16.61.5 Related commands

print

### 16.61.6 Default

The out option has the default screen.
The styles option has the default all.

### 16.62 jump command

#### 16.62.1 Syntax

```
jump file label
```

- file = filename of new input script to switch to
- label = optional label within file to jump to

#### 16.62.2 Examples

```
jump newfile
jump in.run2 runloop
jump SELF runloop
```

#### 16.62.3 Description

This command closes the current input script file, opens the file with the specified name, and begins reading LAMMPS commands from that file. Unlike the include command, the original file is not returned to, although by using multiple jump commands it is possible to chain from file to file or back to the original file.

If the word “SELF” is used for the filename, then the current input script is re-opened and read again.

**Note:** The SELF option is not guaranteed to work when the current input script is being read through stdin (standard input), e.g.

```
lmp_g++ < in.script
```

since the SELF option invokes the C-library rewind() call, which may not be supported for stdin on some systems or by some MPI implementations. This can be worked around by using the -in command-line switch, e.g.
LAMMPS Documentation, Release patch 23Jun2022

```
lmp_g++ -in in.script
```

or by using the `-var command-line switch` to pass the script name as a variable to the input script. In the latter case, a `variable` called “fname” could be used in place of SELF, e.g.

```
lmp_g++ -var fname in.script < in.script
```

The second argument to the jump command is optional. If specified, it is treated as a label and the new file is scanned (without executing commands) until the label is found, and commands are executed from that point forward. This can be used to loop over a portion of the input script, as in this example. These commands perform 10 runs, each of 10000 steps, and create 10 dump files named file.1, file.2, etc. The `next` command is used to exit the loop after 10 iterations. When the “a” variable has been incremented for the tenth time, it will cause the next jump command to be skipped.

```
variable a loop 10
label loop
dump 1 all atom 100 file.$a
run 10000
undump 1
next a
jump in.lj loop
```

If the jump `file` argument is a variable, the jump command can be used to cause different processor partitions to run different input scripts. In this example, LAMMPS is run on 40 processors, with 4 partitions of 10 proc each. An in.file containing the example variable and jump command will cause each partition to run a different simulation.

```
mpirun -np 40 lmp_ibm -partition 4x10 -in in.file

variable f world script.1 script.2 script.3 script.4
jump $f
```

Here is an example of a loop which checks every 1000 steps if the system temperature has reached a certain value, and if so, breaks out of the loop to finish the run. Note that any variable could be checked, so long as it is current on the timestep when the run completes. As explained on the `variable` doc page, this can be insured by including the variable in thermodynamic output.

```
variable myTemp equal temp
label loop
variable a loop 1000
run 1000
if "${myTemp} < 300.0" then "jump SELF break"
next a
jump SELF loop
label break
print "ALL DONE"
```

Here is an example of a double loop which uses the if and `jump` commands to break out of the inner loop when a condition is met, then continues iterating through the outer loop.

```
label loop
variable a loop 5
label loopb
variable b loop 5
print "A,B = $a,$b"
run 10000
```

(continues on next page)
16.62.4 Restrictions

If you jump to a file and it does not contain the specified label, LAMMPS will come to the end of the file and exit.

16.62.5 Related commands

variable, include, label, next

16.63 kim command

16.63.1 Syntax

```
 kim sub-command args
```

- sub-command = init or interactions or query or param or property
- args = arguments used by a particular sub-command

16.63.2 Examples

```
kim init args
kim interactions args
kim query args
kim param args
kim property args
```
16.63.3 Description

The **kim command** includes a set of sub-commands that allow LAMMPS users to use interatomic models (IM) (potentials and force fields) and their predictions for various physical properties archived in the Open Knowledgebase of Interatomic Models (OpenKIM) repository.

Using OpenKIM provides LAMMPS users with immediate access to a large number of verified IMs and their predictions. OpenKIM IMs have multiple benefits including **reliability, reproducibility and convenience**.

There are two types of IMs archived in OpenKIM:

1. The first type is called a *KIM Portable Model* (PM). A KIM PM is an independent computer implementation of an IM written in one of the languages supported by KIM (C, C++, Fortran) that conforms to the KIM Application Programming Interface (KIM API) Portable Model Interface (PMI) standard. A KIM PM will work seamlessly with any simulation code that supports the KIM API/PMI standard (including LAMMPS; see complete list of supported codes).

2. The second type is called a *KIM Simulator Model* (SM). A KIM SM is an IM that is implemented natively within a simulation code (*simulator*) that supports the KIM API Simulator Model Interface (SMI); in this case LAMMPS. A separate SM package is archived in OpenKIM for each parameterization of the IM, which includes all of the necessary parameter files, LAMMPS commands, and metadata (supported species, units, etc.) needed to run the IM in LAMMPS.

With these two IM types, OpenKIM can archive and test almost all IMs that can be used by LAMMPS. (It is easy to contribute new IMs to OpenKIM, see the upload instructions.)

OpenKIM IMs are uniquely identified by a **KIM ID**. The extended KIM ID consists of a human-readable prefix identifying the type of IM, authors, publication year, and supported species, separated by two underscores from the KIM ID itself, which begins with an IM code (**MO** for a KIM Portable Model, and **SM** for a KIM Simulator Model) followed by a unique 12-digit code and a 3-digit version identifier. By convention SM prefixes begin with **Sim_** to readily identify them.

| SW_StillingerWeber_1985_Si__MO_405512056662_005 | Sim_LAMMPS_ReaxFF_StrachanVanDuinChakraborty_2003_CHNO__SM_107643900657_001 |

Each OpenKIM IM has a dedicated “Model Page” on OpenKIM providing all the information on the IM including a title, description, authorship and citation information, test and verification check results, visualizations of results, a wiki with documentation and user comments, and access to raw files, and other information. The URL for the Model Page is constructed from the extended KIM ID of the IM:

```
https://openkim.org/id/extended_KIM_ID
```

For example, for the Stillinger-Weber potential listed above the Model Page is located at:

```
https://openkim.org/id/SW_StillingerWeber_1985_Si__MO_405512056662_005
```

See the current list of KIM PMs and SMs archived in OpenKIM. This list is sorted by species and can be filtered to display only IMs for certain species combinations.

See Obtaining KIM Models to learn how to install a pre-built binary of the OpenKIM Repository of Models.

**Note:** It is also possible to locally install IMs not archived in OpenKIM, in which case their names do not have to conform to the KIM ID format.
16.63.4 Using OpenKIM IMs with LAMMPS *(kim init, kim interactions)*

Two sub-commands are employed when using OpenKIM IMs in LAMMPS, one to select the IM and perform necessary initialization *(kim init)*, and the second to set up the IM for use by executing any necessary LAMMPS commands *(kim interactions)*. Both are required.

**Syntax**

```
kim init model user_units unitarg
kim interactions typeargs
```

- `model` = name of the KIM interatomic model (the KIM ID for models archived in OpenKIM)
- `user_units` = the LAMMPS units style assumed in the LAMMPS input script
- `unitarg` = `unit_conversion_mode` (optional)
- `typeargs` = atom type to species mapping (one entry per atom type) or `fixed_types` for models with a preset fixed mapping

**Examples**

```
kim init SW_StillingerWeber_1985_Si__MO_405512056662_005 metal
kim interactions Si

kim init Sim_LAMMPS_ReaxFF_StrachanVanDuinChakraborty_2003_CHNO__SM_107643900657_001 real
kim init Sim_LAMMPS_ReaxFF_StrachanVanDuinChakraborty_2003_CHNO__SM_107643900657_001
    → metal unit_conversion_mode
kim interactions C H O

kim init Sim_LAMMPS_IFF_PCFF_HeinzMishraLinEmami_2015Ver1v5_FccmetalsMineralsSolventsPolymers__SM_039297821658_000 real
kim interactions fixed_types
```

See the `examples/kim` directory for example input scripts that use KIM PMs and KIM SMs.

**OpenKIM IM Initialization *(kim init)***

The *kim* command followed by *init* sub-command must be issued **before** the simulation box is created (normally at the top of the file). This command sets the OpenKIM IM that will be used and may issue additional commands changing LAMMPS default settings that are required for using the selected IM (such as `units` or `atom_style`). If needed, those settings can be overridden, however, typically a script containing a *kim init* command would not include `units` and `atom_style` commands.

The required arguments of *kim init* are the `model` name of the IM to be used in the simulation (for an IM archived in OpenKIM this is its extended KIM ID, and the `user_units`, which are the LAMMPS units style used in the input script. (Any dimensioned numerical values in the input script and values read in from files are expected to be in the `user_units` system.)

The selected IM can be either a **KIM PM or a KIM SM**. For a KIM SM, the *kim init* command verifies that the SM is designed to work with LAMMPS (and not another simulation code). In addition, the LAMMPS version used for defining the SM and the LAMMPS version being currently run are printed to help diagnose any incompatible changes to input script or command syntax between the two LAMMPS versions.
Based on the selected model, kim init may modify the atom style. Some SMs have requirements for this setting. If this is the case, then atom_style will be set to the required style. Otherwise, the value is left unchanged (which in the absence of an atom_style command in the input script is the default atom_style value).

Regarding units, the kim init behaves in different ways depending on whether or not unit conversion mode is activated as indicated by the optional unitarg argument. If unit conversion mode is not active, then user_units must either match the required units of the IM or the IM must be able to adjust its units to match. (The latter is only possible with some KIM PMs; SMs can never adjust their units.) If a match is possible, the LAMMPS units command is called to set the units to user_units. If the match fails, the simulation is terminated with an error. The kim init command also sets the default value for the skin (extra distance beyond force cutoff) as 2.0 Angstroms and sets the default value for the timestep size as 1.0 femtosecond.

Here is an example of a LAMMPS script to compute the cohesive energy of a face-centered cubic (fcc) lattice for the MEAM potential by Pascuet and Fernandez (2015) for Al.

```lmp
kim init Sim_LAMMPS_MEAM_PascuetFernandez_2015_Al_SM_811588957187_000 metal
boundary p p p
lattice fcc 4.049
region simbox block 0 1 0 1 0 1 units lattice
create_box 1 simbox
create_atoms 1 box
mass 1 26.981539
kim interactions Al
run 0
variable Ec equal (pe/count(all))
print "Cohesive Energy = ${Ec} eV"
```

The above script will end with an error in the kim init line if the IM is changed to another potential for Al that does not work with metal units. To address this, kim init offers the unit_conversion_mode as shown below.

If unit conversion mode is active, then kim init calls the LAMMPS units command to set the units to the IM’s required or preferred units. Conversion factors between the IM’s units and the user_units are defined for all physical quantities (mass, distance, etc.). (Note that converting to or from the “lj” unit style is not supported.) These factors are stored as internal style variables with the following standard names:

```
_u_mass
_u_distance
_u_time
_u_energy
_u_velocity
_u_force
_u_torque
_u_temperature
_u_pressure
_u_viscosity
_u_charge
_u_dipole
_u_efield
_u_density
```

If desired, the input script can be designed to work with these conversion factors so that the script will work without change with any OpenKIM IM. (This approach is used in the OpenKIM Testing Framework.)

For example, the script given above for the cohesive energy of fcc Al can be rewritten to work with any IM regardless of units. The following script constructs an fcc lattice with a lattice parameter defined in meters, computes the total energy, and prints the cohesive energy in Joules regardless of the units of the IM.
kim init Sim_LAMMPS_MEAM_PascuetFernandez_2015_Al__SM_811588957187_000 si unit_conversion_mode
boundary p p p
lattice fcc $(4.049e-10*v__u_distance)
region simbox block 0 1 0 1 0 1 units lattice
create_box 1 simbox
create_atoms 1 box
mass 1 $(4.480134e-26*v__u_mass)
kim interactions Al
neighbor $(2e-10*v__u_distance) bin
run 0
variable Ec_in_J equal (pe/count(all))/v__u_energy
print "Cohesive Energy = ${Ec_in_J} J"

Note the multiplication by \( v__u\_distance \) and \( v__u\_mass \) to convert from SI units (specified in the \textit{kim init} command) to whatever units the IM uses (metal in this case), and the division by \( v__u\_energy \) to convert from the IM’s energy units to SI units (Joule). This script will work correctly for any IM for Al (KIM PM or SM) selected by the \textit{kim init} command.

Care must be taken to apply unit conversion to dimensional variables read in from a file. For example, if a configuration of atoms is read in from a dump file using the \textit{read_dump} command, the following can be done to convert the box and all atomic positions to the correct units:

\texttt{change\_box all x scale \{v__u\_distance\} \\
\hspace*{1em} y scale \{v__u\_distance\} \\
\hspace*{1em} z scale \{v__u\_distance\} \\
\hspace*{1em} xy final $(xy*v__u\_distance) \\
\hspace*{1em} xz final $(xz*v__u\_distance) \\
\hspace*{1em} yz final $(yz*v__u\_distance) \\
\hspace*{1em} remap}

\textbf{Note:} Unit conversion will only work if the conversion factors are placed in all appropriate places in the input script. It is up to the user to do this correctly.

**OpenKIM IM Execution (\textit{kim interactions})**

The second and final step in using an OpenKIM IM is to execute the \textit{kim interactions} command. This command must be preceded by a \textit{kim init} command and a command that defines the number of atom types \( N \) (such as \textit{create\_box}). The \textit{kim interactions} command has one argument \textit{typeargs}. This argument contains either a list of \( N \) chemical species, which defines a mapping between atom types in LAMMPS to the available species in the OpenKIM IM, or the keyword \textit{fixed\_types} for models that have a preset fixed mapping (i.e., the mapping between LAMMPS atom types and chemical species is defined by the model and cannot be changed). In the latter case, the user must consult the model documentation to see how many atom types there are and how they map to the chemical species.

For example, consider an OpenKIM IM that supports Si and C species. If the LAMMPS simulation has four atom types, where the first three are Si, and the fourth is C, the following \textit{kim interactions} command would be used:

\texttt{kim interactions Si Si Si C}

Alternatively, for a model with a fixed mapping the command would be:
The `kim interactions` command performs all the necessary steps to set up the OpenKIM IM selected in the `kim init` command. The specific actions depend on whether the IM is a KIM PM or a KIM SM. For a KIM PM, a `pair_style` command is executed followed by the appropriate `pair_coeff` command. For example, for the Ercolessi and Adams (1994) KIM PM for Al set by the following commands:

```
kim init EAM_Dynamo_ErcolessiAdams_1994_Ai__MO_123629422045_005 metal
...  box specification lines skipped
...  kim interactions Al
```

the `kim interactions` command executes the following LAMMPS input commands:

```
pair_style  kim EAM_Dynamo_ErcolessiAdams_1994_Ai__MO_123629422045_005
pair_coeff  * * Al
```

For a KIM SM, the generated input commands may be more complex and require that LAMMPS is built with the required packages included for the type of potential being used. The set of commands to be executed is defined in the SM specification file, which is part of the SM package. For example, for the Strachan et al. (2003) ReaxFF SM set by the following commands:

```
kim init Sim_LAMMPS_ReaxFF_StrachanVanDuinChakraborty_2003_CHNO__SM_107643900657_000 real
...  box specification lines skipped
...  kim interactions C H N O
```

the `kim interactions` command executes the following LAMMPS input commands:

```
pair_style  reaxff lmp_control safezone 2.0 mincap 100
pair_coeff  * * ffield.reax.rdx C H N O
fix reaxqeq all qeq/reaxff 1 0.0 10.0 1.0e-6 param.qeq
```

Note: The files `lmp_control`, `ffield.reax.rdx`, and `param.qeq` are specific to the Strachan et al. (2003) ReaxFF parameterization and are archived as part of the SM package in OpenKIM.

Note: Parameters like cutoff radii and charge tolerances, which have an effect on IM predictions, are also included in the SM definition ensuring reproducibility.

Note: When using `kim init` and `kim interactions` to select and set up an OpenKIM IM, other LAMMPS commands for the same functions (such as `pair_style`, `pair_coeff`, `bond_style`, `bond_coeff`, `fixes` related to charge equilibration, etc.) should normally not appear in the input script.

Note: `kim interactions` must be called each time after the `change_box` command to provide the correct settings (it should be called with the same `typeargs` as the first call.) The reason is that changing a periodic boundary to a non-periodic one, or in general, using the `change_box` command after the interactions are set via `kim interactions` or `pair_coeff` commands might affect some of the settings. For example, SM models containing Coulombic terms in the interactions
require different settings if a periodic boundary changes to a non-periodic one. In other cases, the second call to *kim interactions* does not affect any other settings.

## 16.63.5 Using OpenKIM Web Queries in LAMMPS (*kim query*)

The *kim query* command performs a web query to retrieve the predictions of an IM set by *kim init* for material properties archived in OpenKIM.

### Syntax

```
kim query variable formatarg query_function queryargs
```

- **variable(s)** = single name or list of names of (string style) LAMMPS variable(s) where a query result or parameter get result is stored. Variables that do not exist will be created by the command
- **formatarg** = *list*, *split*, or *index* (optional):
  - *list* = returns a single string with a list of space separated values (e.g. "1.0 2.0 3.0"), which is placed in a LAMMPS variable as defined by the *variable* argument. [default]
  - *split* = returns the values separately in new variables with names based on the prefix specified in *variable* and a number appended to indicate which element in the list of values is in the variable
  - *index* = returns a variable style index that can be incremented via the next command. This enables the construction of simple loops
- **query_function** = name of the OpenKIM web API query function to be used
- **queryargs** = a series of *keyword=value* pairs that represent the web query; supported keywords depend on the query function

### Examples

```
kim query a0 get_lattice_constant_cubic crystal=[fcc] species=[Al] units=[angstrom]
kim query model index get_available_models species=[Al] potential_type=[eam]
```

The result of the query is stored in one or more *string style variables* as determined by the optional *formatarg* argument. For the “list” setting of *formatarg* (or if *formatarg* is not specified), the result is returned as a space-separated list of values in *variable*. The *formatarg* keyword “split” separates the result values into individual variables of the form *prefix_*I*, where *prefix* is set to the *kim query variable* argument and *I* ranges from 1 to the number of returned values. The number and order of the returned values is determined by the type of query performed. The *formatarg* keyword “index” returns a *variable style index* that can be incremented via the *next* command. This enables the construction of simple loops over the returned values by the type of query performed.

**Note:** *kim query* only supports queries that return a single result or an array of values. More complex queries that return a JSON structure are not currently supported. An attempt to use *kim query* in such cases will generate an error.

The second required argument *query_function* is the name of the query function to be called (e.g. *get_lattice_constant_cubic*). All following *arguments* are parameters handed over to the web query in the format *keyword=value*, where *value* is always an array of one or more comma-separated items in brackets. The list of supported
keywords and the type and format of their values depend on the query function used. The current list of query functions is available on the OpenKIM webpage at https://openkim.org/doc/usage/kim-query.

**Note:** All query functions, except `get_available_models`, require the `model` keyword, which identifies the IM whose predictions are being queried. `kim query` automatically generates the `model` keyword based on the IM set in by `kim init`, and it can be overwritten if specified as an argument to the `kim query`. Where `kim init` is not specified, the `model` keyword must be provided as an argument to the `kim query`.

**Note:** Each `query_function` is associated with a default method (implemented as a KIM Test) used to compute this property. In cases where there are multiple methods in OpenKIM for computing a property, a `method` keyword can be provided to select the method of choice. See the query documentation to see which methods are available for a given `query_function`.

### kim query Usage Examples and Further Clarifications

The data obtained by `kim query` commands can be used as part of the setup or analysis phases of LAMMPS simulations. Some examples are given below.

#### Define an equilibrium fcc crystal

```bash
kim init EAM_Dynamo_ErcolessiAdams_1994_Al__MO_123629422045_005 metal
boundary p p p
kim query a0 get_lattice_constant_cubic crystal=[fcc] species=[Al] units=[angstrom]
lattice fcc ${a0}
...
```

```bash
units metal
kim query a0 get_lattice_constant_cubic crystal=[fcc] species=[Al] units=[angstrom]
          _model=[EAM_Dynamo_ErcolessiAdams_1994_Al__MO_123629422045_005]
lattice fcc ${a0}
...
```

The `kim query` command retrieves from OpenKIM the equilibrium lattice constant predicted by the Ercolessi and Adams (1994) potential for the fcc structure and places it in variable `a0`. This variable is then used on the next line to set up the crystal. By using `kim query`, the user is saved the trouble and possible error of tracking this value down, or of having to perform an energy minimization to find the equilibrium lattice constant.

**Note:** In `unit_conversion_mode` the results obtained from a `kim query` would need to be converted to the appropriate units system. For example, in the above script, the lattice command would need to be changed to: “lattice fcc $(v_a0*v_distance)”.

#### Define an equilibrium hcp crystal

```bash
kim init EAM_Dynamo_MendelevAckland_2007v3_Zr__MO_004835508849_000 metal
boundary p p p
kim query latconst split get_lattice_constant_hexagonal crystal=[hcp] species=[Zr]
          _units=[angstrom]
lattice custom ${latconst_1} a1 0.5 -0.866025 0 a2 0.5 0.866025 0 a3 0 0 $(latconst_2/
          _latconst_1) &
```

(continues on next page)
Define a crystal at finite temperature accounting for thermal expansion

```
kim    init EAM_Dynamo_ErcolessiAdams_1994_Al__MO_123629422045_005 metal
boundary p p p
kim    query a0 get_lattice_constant_cubic crystal=[fcc] species=[Al] units=[angstrom]
kim    query alpha get_linear_thermal_expansion_coefficient_cubic crystal=[fcc]␣
variable DeltaT equal 300
lattice fcc $(v_a0*v_alpha*v_DeltaT)
```

As in the previous example, the equilibrium lattice constant is obtained for the Ercolessi and Adams (1994) potential. However, in this case the crystal is scaled to the appropriate lattice constant at room temperature (293.15 K) by using the linear thermal expansion constant predicted by the potential.

**Note:** When passing numerical values as arguments (as in the case of the temperature in the above example) it is also possible to pass a tolerance indicating how close to the value is considered a match. If no tolerance is passed a default value is used. If multiple results are returned (indicating that the tolerance is too large), *kim query* will return an error. See the query documentation to see which numerical arguments and tolerances are available for a given *query_function*.

Compute defect formation energy

```
kim    init EAM_Dynamo_ErcolessiAdams_1994_Al__MO_123629422045_005 metal
... Build fcc crystal containing some defect and compute the total energy
... which is stored in the variable *Etot*
... query Ec get_cohesive_energy_cubic crystal=[fcc] species=[Al] units=[eV]
variable Eform equal ${Etot} - count(all)*${Ec}
```

The defect formation energy *Eform* is computed by subtracting the ideal fcc cohesive energy of the atoms in the system from *Etot*. The ideal fcc cohesive energy of the atoms is obtained from OpenKIM for the Ercolessi and Adams (1994) potential.

Retrieve equilibrium fcc crystal of all EAM potentials that support a specific species

```
kim    query model index get_available_models species=[Al] potential_type=[eam]
label model_loop
kim    query latconst get_lattice_constant_cubic crystal=[fcc] species=[Al]␣
    →units=[angstrom] model=[${model}]
print "FCC lattice constant ({$model} potential) = ${latconst}"
... do something with current value of latconst
```

In this example, the index mode of formatarg is used. The first kim query returns the list of all available EAM potentials that support the Al species and archived in OpenKIM. The result of the query operation is stored in the LAMMPS variable model as an index variable. This variable is used later to access the values one at a time within a loop as shown in the example. The second kim query command retrieves from OpenKIM the equilibrium lattice constant predicted by each potential for the fcc structure and places it in variable latconst.

Note: kim query commands return results archived in OpenKIM. These results are obtained using programs for computing material properties (KIM Tests and KIM Test Drivers) that were contributed to OpenKIM. In order to give credit to Test developers, the number of times results from these programs are queried is tracked. No other information about the nature of the query or its source is recorded.

16.63.6 Accessing KIM Model Parameters from LAMMPS (kim param)

All IMs are functional forms containing a set of parameters. These parameters’ values are typically selected to best reproduce a training set of quantum mechanical calculations or available experimental data. For example, a Lennard-Jones potential intended to model argon might have the values of its two parameters, epsilon, and sigma, fit to the dimer dissociation energy or thermodynamic properties at a critical point of the phase diagram.

Normally a user employing an IM should not modify its parameters since, as noted above, these are selected to reproduce material properties. However, there are cases where accessing and modifying IM parameters is desired, such as for assessing uncertainty, fitting an IM, or working with an ensemble of IMs. As explained above, IMs archived in OpenKIM are either Portable Models (PMs) or Simulator Models (SMs). KIM PMs are complete independent implementations of an IM, whereas KIM SMs are wrappers to an IM implemented within LAMMPS. Two different mechanisms are provided for accessing IM parameters in these two cases:

- For a KIM PM, the kim param command can be used to get and set the values of the PM’s parameters as explained below.

- For a KIM SM, the user should consult the documentation page for the specific IM and follow instructions there for how to modify its parameters (if possible).

The kim param get and kim param set commands provide an interface to access and change the parameters of a KIM PM that “publishes” its parameters and makes them publicly available (see the KIM API documentation for details).

Note: The kim param set/get command must be preceded by a kim interactions command (or alternatively by a pair_style kim and pair_coeff commands). The kim param set command may be used wherever a pair_coeff command may occur.
Syntax

```
kim param get param_name index_range variable formatarg
kim param set param_name index_range values
```

- `param_name` = name of a KIM portable model parameter (which is published by the PM and available for access). The specific string used to identify a parameter is defined by the PM. For example, for the Stillinger-Weber (SW) potential in OpenKIM, the parameter names are `A`, `B`, `p`, `q`, `sigma`, `gamma`, `cutoff`, `lambda`, `costheta0`

- `index_range` = KIM portable model parameter index range (an integer for a single element, or pair of integers separated by a colon for a range of elements)

- `variable(s)` = single name or list of names of (string style) LAMMPS variable(s) where a query result or parameter get result is stored. Variables that do not exist will be created by the command

- `formatarg` = `list`, `split`, or `explicit` (optional): .. parsed-literal:
  
  *list* = returns a single string with a list of space separated values (e.g. "1.0 2.0 3.0"), which is placed in a LAMMPS variable as defined by the *variable* argument.

  *split* = returns the values separately in new variables with names based on the prefix specified in *variable* and a number appended to indicate which element in the list of values is in the variable

  *explicit* = returns the values separately in one more more variable names provided as arguments that precede *formatarg*\ . [default]

- `values` = new value(s) to replace the current value(s) of a KIM portable model parameter

Note: The list of all the parameters that a PM exposes for access/mutation are automatically written to the lammps log file when `kim init` is called.

Each published parameter of a KIM PM takes the form of an array of numerical values. The array can contain one element for a single-valued parameter, or a set of values. For example, the multispecies SW potential for the Zn-Cd-Hg-S-Se-Te system has the same parameter names as the single-species SW potential, but each parameter array contains 21 entries that correspond to the parameter values used for each pairwise combination of the model’s six supported species (this model does not have parameters specific to individual ternary combinations of its supported species).

The `index_range` argument may either be an integer referring to a specific element within the array associated with the parameter specified by `param_name`, or a pair of integers separated by a colon that refer to a slice of this array. In both cases, one-based indexing is used to refer to the entries of the array.

The result of a get operation for a specific `index_range` is stored in one or more LAMMPS string style variables as determined by the optional `formatarg` argument documented above. If not specified, the default for `formatarg` is “explicit” for the `kim param` command.

For the case where the result is an array with multiple values (i.e. `index_range` contains a range), the optional “split” or “explicit” `formatarg` keywords can be used to separate the results into multiple variables; see the examples below. Multiple parameters can be retrieved with a single call to `kim param get` by repeating the argument list following `get`.

For a set operation, the `values` argument contains the new value(s) for the element(s) of the parameter specified by `index_range`. For the case where multiple values are being set, `values` contains a set of values separated by spaces. Multiple parameters can be set with a single call to `kim param set` by repeating the argument list following `set`. 

806 Chapter 16. Commands
kim param Usage Examples and Further Clarifications

Examples of getting and setting KIM PM parameters with further clarifications are provided below.

Getting a scalar parameter

```bash
kim init SW_StillingerWeber_1985_Si__MO_405512056662_005 metal
... 
kim interactions Si 
kim param get A 1 VARA
```

or

```bash
... 
pair_style kim SW_StillingerWeber_1985_Si__MO_405512056662_005 
pair_coeff * * Si 
kim param get A 1 VARA
```

In these cases, the value of the SW $A$ parameter is retrieved and placed in the LAMMPS variable VARA. The variable VARA can be used in the remainder of the input script in the same manner as any other LAMMPS variable.

Getting multiple scalar parameters with a single call

```bash
... 
kim interactions Si 
kim param get A 1 VARA B 1 VARB
```

In this example, it is shown how to retrieve the $A$ and $B$ parameters of the SW potential and store them in the LAMMPS variables VARA and VARB.

Getting a range of values from a parameter

There are several options when getting a range of values from a parameter determined by the `formatarg` argument.

```bash
kim init SW_ZhouWardMartin_2013_CdTeZnSeHgS__MO_503261197030_002 metal 
... 
kim interactions Te Zn Se 
kim param get lambda 7:9 LAM_TeTe LAM_TeZn LAM_TeSe
```

In this case, `formatarg` is not specified and therefore the default “explicit” mode is used. (The behavior would be the same if the word `explicit` were added after `LAM_TeSe`.) Elements 7, 8 and 9 of parameter lambda retrieved by the `get` operation are placed in the LAMMPS variables `LAM_TeTe`, `LAM_TeZn` and `LAM_TeSe`, respectively.

Note: In the above example, elements 7-9 of the lambda parameter correspond to Te-Te, Te-Zn and Te-Se interactions. This can be determined by visiting the model page for the specified potential and looking at its parameter file linked to at the bottom of the page (file with .param ending) and consulting the README documentation provided with the driver for the PM being used. A link to the driver is provided at the top of the model page.

```bash
... 
kim interactions Te Zn Se 
kim param get lambda 15:17 LAMS list 
variable LAM_VALUE index ${LAMS} 
label loop_on_lambda 
... 
... do something with the current value of lambda
```

(continues on next page)
In this case, the “list” mode of `formatarg` is used. The result of the `get` operation is stored in the LAMMPS variable `LAMS` as a string containing the three retrieved values separated by spaces, e.g. “1.0 2.0 3.0”. This can be used in LAMMPS with an `index` variable to access the values one at a time within a loop as shown in the example. At each iteration of the loop `LAM_VALUE` contains the current value of lambda.

In this case, the “split” mode of `formatarg` is used. The three values retrieved by the `get` operation are stored in the three LAMMPS variables `LAM_15`, `LAM_16` and `LAM_17`. The provided name “LAM” is used as prefix and the location in the lambda array is appended to create the variable names.

### Setting a scalar parameter

```lmp
kim init SW_StillingerWeber_1985_Si__MO_405512056662_005 metal
kim interactions Si
kim param set gamma 1 2.6

Here, the SW potential’s gamma parameter is set to 2.6. Note that the `get` and `set` commands work together, so that a `get` following a `set` operation will return the new value that was set. For example,

```lmp
kim interactions Si
kim param get gamma 1 ORIG_GAMMA
kim param set gamma 1 2.6
kim param get gamma 1 NEW_GAMMA

Here, `ORIG_GAMMA` will contain the original gamma value for the SW potential, while `NEW_GAMMA` will contain the value 2.6.

### Setting multiple scalar parameters with a single call

```lmp
kim init SW_ZhouWardMartin_2013_CdTeZnSeHgS__MO_503261197030_002 metal
kim interactions Cd Te
variable VARG equal 2.6
variable VARS equal 2.0951
kim param set gamma 1 `${VARG}`
   sigma 3 `${VARS}`

In this case, the first element of the `gamma` parameter and third element of the `sigma` parameter are set to 2.6 and 2.0951, respectively. This example also shows how LAMMPS variables can be used when setting parameters.

### Setting a range of values of a parameter

```lmp
kim init SW_ZhouWardMartin_2013_CdTeZnSeHgS__MO_503261197030_002 metal

(continues on next page)
In this case, elements 2 through 6 of the parameter \( \sigma \) are set to the values 2.35214, 2.23869, 2.04516, 2.43269 and 1.80415 in order.

### 16.63.7 Writing material properties in standard KIM Property Instance format (\textit{kim property})

The OpenKIM system includes a collection of Tests (material property calculation codes), Models (interatomic potentials), Predictions, and Reference Data (DFT or experiments). Specifically, a KIM Test is a computation that when coupled with a KIM Model generates the prediction of that model for a specific material property rigorously defined by a KIM Property Definition (see the KIM Properties Framework for further details). A prediction of a material property for a given model is a specific numerical realization of a property definition, referred to as a “Property Instance.” The objective of the \textit{kim property} command is to make it easy to output material properties in a standardized, machine readable format that can be easily ingested by other programs. Additionally, it aims to make it as easy as possible to convert a LAMMPS script that computes a material property into a KIM Test that can then be uploaded to openkim.org

A developer interested in creating a KIM Test using a LAMMPS script should first determine whether a property definition that applies to their calculation already exists in OpenKIM by searching the properties page. If none exists, it is possible to use a locally defined property definition contained in a file until it can be uploaded to the official repository (see below). Once one or more applicable property definitions have been identified, the \textit{kim property create}, \textit{kim property modify}, \textit{kim property remove}, and \textit{kim property destroy}, commands provide an interface to create, set, modify, remove, and destroy instances of them within a LAMMPS script.

### Syntax

- \texttt{kim property create} instance\_id property\_id
- \texttt{kim property modify} instance\_id key key\_name key\_name\_key key\_name\_value
- \texttt{kim property remove} instance\_id key key\_name
- \texttt{kim property destroy} instance\_id
- \texttt{kim property dump} file

- instance\_id = a positive integer identifying the KIM property instance; (note that the results file can contain multiple property instances)
- property\_id = identifier of a KIM Property Definition, which can be (1) a property short name, (2) the full unique ID of the property (including the contributor and date), (3) a file name corresponding to a local property definition file
- key\_name = one of the keys belonging to the specified KIM property definition
- key\_name\_key = a key belonging to a key-value pair (standardized in the KIM Properties Framework)
- key\_name\_value = value to be associated with a key\_name\_key in a key-value pair
- file = name of a file to write the currently defined set of KIM property instances to

Examples of each of the three property\_id cases are shown below,

- \texttt{kim property create} 1 atomic-mass
- \texttt{kim property create} 2 cohesive-energy-relation-cubic-crystal

16.63. \textit{kim command}
In the last example, “new-property.edn” and “/home/mary/marys-kim-properties/dissociation-energy.edn” are the names of files that contain user-defined (local) property definitions.

A KIM property instance takes the form of a “map,” i.e. a set of key-value pairs akin to Perl’s hash, Python’s dictionary, or Java’s Hashtable. It consists of a set of property key names, each of which is referred to here by the key_name argument, that are defined as part of the relevant KIM Property Definition and include only lowercase alphanumeric characters and dashes. The value paired with each property key is itself a map whose possible keys are defined as part of the KIM Properties Framework; these keys are referred to by the key_name_key argument and their associated values by the key_name_value argument. These values may either be scalars or arrays, as stipulated in the property definition.

Note: Each map assigned to a key_name must contain the key_name_key “source-value” and an associated key_name_value of the appropriate type (as defined in the relevant KIM Property Definition). For keys that are defined as having physical units, the “source-unit” key_name_key must also be given a string value recognized by GNU units.

Once a kim property create command has been given to instantiate a property instance, maps associated with the property’s keys can be edited using the kim property modify command. In using this command, the special keyword “key” should be given, followed by the property key name and the key-value pair in the map associated with the key that is to be set. For example, the atomic-mass property definition consists of two property keys named “mass” and “species.” An instance of this property could be created like so:

```
kim property create 1 atomic-mass
kim property modify 1 key species source-value Al
kim property modify 1 key mass source-value 26.98154
kim property modify 1 key mass source-unit amu
```

or, equivalently,

```
kim property create 1 atomic-mass
kim property modify 1 key species source-value Al &
  key mass source-value 26.98154 &
  source-unit amu
```

**kim property** Usage Examples and Further Clarifications

**Create**

```
kim property create instance_id property_id
```

The kim property create command takes as input a property instance ID and the property definition name, and creates an initial empty property instance data structure. For example,

```
kim property create 1 atomic-mass
kim property create 2 cohesive-energy-relation-cubic-crystal
```
creates an empty property instance of the “atomic-mass” property definition with instance ID 1 and an empty instance of
the “cohesive-energy-relation-cubic-crystal” property with ID 2. A list of published property definitions in OpenKIM
can be found on the properties page.

One can also provide the name of a file in the current working directory or the path of a file containing a valid property
definition. For example,

```
kim property create 1 new-property.edn
```

where “new-property.edn” refers to a file name containing a new property definition that does not exist in OpenKIM.

If the `property_id` given cannot be found in OpenKIM and no file of this name containing a valid property definition
can be found, this command will produce an error with an appropriate message. Calling `kim property create` with the
same instance ID multiple times will also produce an error.

Modify

```
kim property modify instance_id key key_name key_name_key key_name_value
```

The `kim property modify` command incrementally builds the property instance by receiving property definition keys
along with associated arguments. Each `key_name` is associated with a map containing one or more key-value pairs (in
the form of `key_name_key`-`key_name_value` pairs). For example,

```
kim property modify 1 key species source-value Al
kim property modify 1 key mass source-value 26.98154
kim property modify 1 key mass source-unit amu
```

where the special keyword “key” is followed by a `key_name` (“species” or “mass” in the above) and one or more key-
value pairs. These key-value pairs may continue until either another “key” keyword is given or the end of the command
line is reached. Thus, the above could equivalently be written as

```
kim property modify 1 key species source-value Al &
    key mass source-value 26.98154 &
    key mass source-unit amu
```

As an example of modifying multiple key-value pairs belonging to the map of a single property key, the following
command modifies the map of the “cohesive-potential-energy” property key to contain the key “source-unit” which is
assigned a value of “eV” and the key “digits” which is assigned a value of 5,

```
kim property modify 2 key cohesive-potential-energy source-unit eV digits 5
```

**Note:** The relevant data types of the values in the map are handled automatically based on the specification of the key
in the KIM Property Definition. In the example above, this means that the value “eV” will automatically be interpreted
as a string while the value 5 will be interpreted as an integer.

The values contained in maps can either be scalars, as in all of the examples above, or arrays depending on which is
stipulated in the corresponding Property Definition. For one-dimensional arrays, a single one-based index must be
supplied that indicates which element of the array is to be modified. For multidimensional arrays, multiple indices
must be given depending on the dimensionality of the array.

**Note:** All array indexing used by `kim property modify` is one-based, i.e. the indices are enumerated 1, 2, 3, …

**Note:** The dimensionality of arrays are defined in the the corresponding Property Definition. The extent of each
dimension of an array can either be a specific finite number or indefinite and determined at run time. If an array has a fixed extent, attempting to modify an out-of-range index will fail with an error message.

For example, the “species” property key of the cohesive-energy-relation-cubic-crystal property is a one-dimensional array that can contain any number of entries based on the number of atoms in the unit cell of a given cubic crystal. To assign an array containing the string “Al” four times to the “source-value” key of the “species” property key, we can do so by issuing:

```
kim property modify 2 key species source-value 1 Al
kim property modify 2 key species source-value 2 Al
kim property modify 2 key species source-value 3 Al
kim property modify 2 key species source-value 4 Al
```

Note: No declaration of the number of elements in this array was given; `kim property modify` will automatically handle memory management to allow an arbitrary number of elements to be added to the array.

Note: In the event that `kim property modify` is used to set the value of an array index without having set the values of all lesser indices, they will be assigned default values based on the data type associated with the key in the map:

<table>
<thead>
<tr>
<th>Data type</th>
<th>Default value</th>
</tr>
</thead>
<tbody>
<tr>
<td>int</td>
<td>0</td>
</tr>
<tr>
<td>float</td>
<td>0.0</td>
</tr>
<tr>
<td>string</td>
<td>&quot;&quot;</td>
</tr>
<tr>
<td>file</td>
<td>&quot;&quot;</td>
</tr>
</tbody>
</table>

For example, doing the following:

```
kim property create 2 cohesive-energy-relation-cubic-crystal
kim property modify 2 key species source-value 4 Al
```

will result in the “source-value” key in the map for the property key “species” being assigned the array ["", "", "", "Al"].

For convenience, the index argument provided may refer to an inclusive range of indices by specifying two integers separated by a colon (the first integer must be less than or equal to the second integer, and no whitespace should be included). Thus, the snippet above could equivalently be written:

```
kim property modify 2 key species source-value 1:4 Al Al Al Al
```

Calling this command with a non-positive index, e.g. `kim property modify 2 key species source-value 0 Al`, or an incorrect number of input arguments, e.g. `kim property modify 2 key species source-value 1:4 Al Al`, will result in an error.

As an example of modifying multidimensional arrays, consider the “basis-atoms” key in the cohesive-energy-relation-cubic-crystal property definition. This is a two-dimensional array containing the fractional coordinates of atoms in the unit cell of the cubic crystal. In the case of, e.g. a conventional fcc unit cell, the “source-value” key in the map associated with this key should be assigned the following value:

```
[[0.0, 0.0, 0.0],
[0.5, 0.5, 0.0],
```

(continues on next page)
While each of the twelve components could be set individually, we can instead set each row at a time using colon notation:

\[
\begin{align*}
&\text{kim property modify 2 key basis-atom-coordinates source-value 1 1:3 0.0 0.0 0.0} \\
&\text{kim property modify 2 key basis-atom-coordinates source-value 2 1:3 0.5 0.5 0.0} \\
&\text{kim property modify 2 key basis-atom-coordinates source-value 3 1:3 0.5 0.0 0.5} \\
&\text{kim property modify 2 key basis-atom-coordinates source-value 4 1:3 0.0 0.5 0.5}
\end{align*}
\]

Where the first index given refers to a row and the second index refers to a column. We could, instead, choose to set each column at a time like so:

\[
\begin{align*}
&\text{kim property modify 2 key basis-atom-coordinates source-value 1:4 1 0.0 0.5 0.0} \\
&\text{kim property modify 2 key basis-atom-coordinates source-value 1:4 2 0.0 0.0 0.5} \\
&\text{kim property modify 2 key basis-atom-coordinates source-value 1:4 3 0.0 0.5 0.0}
\end{align*}
\]

Note: Multiple calls of \text{kim property modify} made for the same instance ID can be combined into a single invocation, meaning the following are both valid:

\[
\begin{align*}
&\text{kim property modify 2 key basis-atom-coordinates source-value 1 1:3 0.0 0.0 0.0} \\
&\text{kim property modify 2 key basis-atom-coordinates source-value 2 1:3 0.5 0.5 0.0} \\
&\text{kim property modify 2 key basis-atom-coordinates source-value 3 1:3 0.5 0.0 0.5} \\
&\text{kim property modify 2 key basis-atom-coordinates source-value 4 1:3 0.0 0.5 0.5}
\end{align*}
\]

Note: For multidimensional arrays, only one colon-separated range is allowed in the index listing. Therefore,

\[
\begin{align*}
&\text{kim property modify 2 key basis-atom-coordinates 1 1:3 0.0 0.0 0.0}
\end{align*}
\]

is valid but

\[
\begin{align*}
&\text{kim property modify 2 key basis-atom-coordinates 1:2 1:3 0.0 0.0 0.0 0.0 0.0 0.0}
\end{align*}
\]

is not.

Note: After one sets a value in a map with the \text{kim property modify} command, additional calls will overwrite the previous value.
Remove

```
kim property remove instance_id key key_name
```

The `kim property remove` command can be used to remove a property key from a property instance. For example,

```
kim property remove 2 key basis-atom-coordinates
```

Destroy

```
kim property destroy instance_id
```

The `kim property destroy` command deletes a previously created property instance ID. For example,

```
kim property destroy 2
```

Note: If this command is called with an instance ID that does not exist, no error is raised.

Dump

The `kim property dump` command can be used to write the content of all currently defined property instances to a file:

```
kim property dump file
```

For example,

```
kim property dump results.edn
```

Note: Issuing the `kim property dump` command clears all existing property instances from memory.

16.63.8 Citation of OpenKIM IMs

When publishing results obtained using OpenKIM IMs researchers are requested to cite the OpenKIM project (Tadmor), KIM API (Elliott), and the specific IM codes used in the simulations, in addition to the relevant scientific references for the IM. The citation format for an IM is displayed on its page on OpenKIM along with the corresponding BibTex file, and is automatically added to the LAMMPS citation reminder.

Citing the IM software (KIM infrastructure and specific PM or SM codes) used in the simulation gives credit to the researchers who developed them and enables open source efforts like OpenKIM to function.

16.63.9 Restrictions

The `kim` command is part of the KIM package. It is only enabled if LAMMPS is built with that package. A requirement for the KIM package, is the KIM API library that must be downloaded from the OpenKIM website and installed before LAMMPS is compiled. When installing LAMMPS from binary, the kim-api package is a dependency that is automatically downloaded and installed. The `kim query` command requires the libcurl library to be installed. The `kim property` command requires Python 3.6 or later and the `kim-property` python package to be installed. See the KIM section of the Packages details for details.

Furthermore, when using `kim` command to run KIM SMs, any packages required by the native potential being used or other commands or fixes that it invokes must be installed.

16.64.1 Syntax

kspace_modify keyword value ...

- one or more keyword/value pairs may be listed
- keyword = collective or compute or cutoff/adjust or diff or disp/auto or fftbench or force/disp/kspace or force/disp/real or force or gewald/disps or gewald or kmax/ewald or mesh or minorder or mix/disp or order/disp or order or overlap or scafacos or slab or splittol
  - collective value = yes or no
  - compute value = yes or no
  - cutoff/adjust value = yes or no
  - diff value = ad or ik = 2 or 4 FFTs for PPPM in smoothed or non-smoothed mode
  - disp/auto value = yes or no
  - fftbench value = yes or no
  - force/disp/real value = accuracy (force units)
  - force/disp/kspace value = accuracy (force units)
  - force value = accuracy (force units)
  - gewald value = rinv (1/distance units)
    - rinv = G-ewald parameter for Coulombics
  - gewald/disps value = rinv (1/distance units)
    - rinv = G-ewald parameter for dispersion
  - kmax/ewald value = kx ky kz
    - kx,ky,kz = number of Ewald sum kspace vectors in each dimension
  - mesh value = x y z
    - x,y,z = grid size in each dimension for long-range Coulombics
  - mesh/disps value = x y z
    - x,y,z = grid size in each dimension for 1/r^6 dispersion
  - minorder value = M
    - M = min allowed extent of Gaussian when auto-adjusting to minimize grid communication
  - mix/disps value = pair or geom or none
  - order value = N
    - N = extent of Gaussian for PPPM or MSM mapping of charge to grid
  - order/disps value = N
    - N = extent of Gaussian for PPPM mapping of dispersion term to grid
  - overlap = yes or no = whether the grid stencil for PPPM is allowed to overlap into more than the nearest-neighbor processor
  - pressure/scalar value = yes or no
  - scafacos values = option value1 value2 ...
option = tolerance
tolerance = energy or energy_rel or field or field_rel or potential or potential_rel
option = fmm_tuning
value = 0 or 1
slab value = volfactor or nozforce
volfactor = ratio of the total extended volume used in the
2d approximation compared with the volume of the simulation domain
ew2d EW2D correction (available with ELECTRODE package)
nozforce turns off kspace forces in the z direction
splittol value = tol
tol = relative size of two eigenvalues (see discussion below)
wire value = volfactor (available with ELECTRODE package)
volfactor = ratio of the total extended dimension used in the 1d
approximation compared with the dimension of the simulation domain

16.64.2 Examples

```plaintext
kspace_modify mesh 24 24 30 order 6
kspace_modify slab 3.0
kspace_modify scacfacos tolerance energy
```

16.64.3 Description

Set parameters used by the kspace solvers defined by the kspace_style command. Not all parameters are relevant to all kspace styles.

The collective keyword applies only to PPPM. It is set to no by default, except on IBM BlueGene machines. If this option is set to yes, LAMMPS will use MPI collective operations to remap data for 3d-FFT operations instead of the default point-to-point communication. This is faster on IBM BlueGene machines, and may also be faster on other machines if they have an efficient implementation of MPI collective operations and adequate hardware.

The compute keyword allows Kspace computations to be turned off, even though a kspace_style is defined. This is not useful for running a real simulation, but can be useful for debugging purposes or for computing only partial forces that do not include the Kspace contribution. You can also do this by simply not defining a kspace_style, but a Kspace-compatible pair_style requires a kspace style to be defined. This keyword gives you that option.

The cutoff/adjust keyword applies only to MSM. If this option is turned on, the Coulombic cutoff will be automatically adjusted at the beginning of the run to give the desired estimated error. Other cutoffs such as LJ will not be affected. If the grid is not set using the mesh command, this command will also attempt to use the optimal grid that minimizes cost using an estimate given by (Hardy). Note that this cost estimate is not exact, somewhat experimental, and still may not yield the optimal parameters.

The diff keyword specifies the differentiation scheme used by the PPPM method to compute forces on particles given electrostatic potentials on the PPPM mesh. The ik approach is the default for PPPM and is the original formulation used in (Hockney). It performs differentiation in Kspace, and uses 3 FFTs to transfer each component of the computed fields back to real space for total of 4 FFTs per timestep.
The analytic differentiation \textit{ad} approach uses only 1 FFT to transfer information back to real space for a total of 2 FFTs per timestep. It then performs analytic differentiation on the single quantity to generate the 3 components of the electric field at each grid point. This is sometimes referred to as “smoothed” PPPM. This approach requires a somewhat larger PPPM mesh to achieve the same accuracy as the \textit{ik} method. Currently, only the \textit{ik} method (default) can be used for a triclinic simulation cell with PPPM. The \textit{ad} method is always used for MSM.

\textbf{Note:} Currently, not all PPPM styles support the \textit{ad} option. Support for those PPPM variants will be added later.

The \textit{disp/auto} option controls whether the \textit{pppm/disp} is allowed to generate PPPM parameters automatically. If set to \textit{no}, parameters have to be specified using the \textit{gewald/disp}, \textit{mesh/disp}, \textit{force/disp/real} or \textit{force/disp/kspace} keywords, or the code will stop with an error message. When this option is set to \textit{yes}, the error message will not appear and the simulation will start. For a typical application, using the automatic parameter generation will provide simulations that are either inaccurate or slow. Using this option is thus not recommended. For guidelines on how to obtain good parameters, see the \textit{How-To} discussion.

The \textit{fftbench} keyword applies only to PPPM. It is off by default. If this option is turned on, LAMMPS will perform a short FFT benchmark computation and report its timings, and will thus finish some seconds later than it would if this option were off.

The \textit{force/disp/real} and \textit{force/disp/kspace} keywords set the force accuracy for the real and reciprocal space computations for the dispersion part of \textit{pppm/disp}. As shown in \textit{(Isele-Holder)}, optimal performance and accuracy in the results is obtained when these values are different.

The \textit{force} keyword overrides the relative accuracy parameter set by the \textit{kmax/ewald} command with an absolute accuracy. The accuracy determines the RMS error in per-atom forces calculated by the long-range solver and is thus specified in force units. A negative value for the accuracy setting means to use the relative accuracy parameter. The accuracy setting is used in conjunction with the pairwise cutoff to determine the number of K-space vectors for style \textit{ewald}, the FFT grid size for style \textit{pppm}, or the real space grid size for style \textit{msm}.

The \textit{gewald} keyword sets the value of the Ewald or PPPM G-ewald parameter for charge as \textit{rinv} in reciprocal distance units. Without this setting, LAMMPS chooses the parameter automatically as a function of cutoff, precision, grid spacing, etc. This means it can vary from one simulation to the next which may not be desirable for matching a KSpace solver to a pre-tabulated pairwise potential. This setting can also be useful if Ewald or PPPM fails to choose a good grid spacing and G-ewald parameter automatically. If the value is set to 0.0, LAMMPS will choose the G-ewald parameter automatically. MSM does not use the \textit{gewald} parameter.

The \textit{gewald/disp} keyword sets the value of the Ewald or PPPM G-ewald parameter for dispersion as \textit{rinv} in reciprocal distance units. It has the same meaning as the \textit{gewald} setting for Coulombics.

The \textit{kmax/ewald} keyword sets the number of kspace vectors in each dimension for kspace style \textit{ewald}. The three values must be positive integers, or else (0,0,0), which unsets the option. When this option is not set, the Ewald sum scheme chooses its own kspace vectors, consistent with the user-specified accuracy and pairwise cutoff. In any case, if kspace style \textit{ewald} is invoked, the values used are printed to the screen and the log file at the start of the run.
The `mesh` keyword sets the grid size for kspace style `pppm` or `msm`. In the case of PPPM, this is the FFT mesh, and each dimension must be factorizable into powers of 2, 3, and 5. In the case of MSM, this is the finest scale real-space mesh, and each dimension must be factorizable into powers of 2. When this option is not set, the PPPM or MSM solver chooses its own grid size, consistent with the user-specified accuracy and pairwise cutoff. Values for x,y,z of 0,0,0 unset the option.

The `mesh/disp` keyword sets the grid size for kspace style `pppm/disp`. This is the FFT mesh for long-range dispersion and each dimension must be factorizable into powers of 2, 3, and 5. When this option is not set, the PPPM solver chooses its own grid size, consistent with the user-specified accuracy and pairwise cutoff. Values for x,y,z of 0,0,0 unset the option.

The `minorder` keyword allows LAMMPS to reduce the `order` setting if necessary to keep the communication of ghost grid point limited to exchanges between nearest-neighbor processors. See the discussion of the `overlap` keyword for details. If the `overlap` keyword is set to `yes`, which is the default, this is never needed. If it set to `no` and overlap occurs, then LAMMPS will reduce the order setting, one step at a time, until the ghost grid overlap only extends to nearest neighbor processors. The `minorder` keyword limits how small the `order` setting can become. The minimum allowed value for PPPM is 2, which is the default. If `minorder` is set to the same value as `order` then no reduction is allowed, and LAMMPS will generate an error if the grid communication is non-nearest-neighbor and `overlap` is set to `no`. The `minorder` keyword is not currently supported in MSM.

The `mix/disp` keyword selects the mixing rule for the dispersion coefficients. With `pair`, the dispersion coefficients of unlike types are computed as indicated with `pair_modify`. With `geom`, geometric mixing is enforced on the dispersion coefficients in the kspace coefficients. When using the arithmetic mixing rule, this will speed-up the simulations but introduces some error in the force computations, as shown in (Wennberg). With `none`, it is assumed that no mixing rule is applicable. Splitting of the dispersion coefficients will be performed as described in (Isele-Holder).

This splitting can be influenced with the `splittol` keywords. Only the eigenvalues that are larger than tol compared to the largest eigenvalues are included. Using this keywords the original matrix of dispersion coefficients is approximated. This leads to faster computations, but the accuracy in the reciprocal space computations of the dispersion part is decreased.

The `order` keyword determines how many grid spacings an atom’s charge extends when it is mapped to the grid in kspace style `pppm` or `msm`. The default for this parameter is 5 for PPPM and 8 for MSM, which means each charge spans 5 or 8 grid cells in each dimension, respectively. For the LAMMPS implementation of MSM, the order can range from 4 to 10 and must be even. For PPPM, the minimum allowed setting is 2 and the maximum allowed setting is 7. The larger the value of this parameter, the smaller that LAMMPS will set the grid size, to achieve the requested accuracy. Conversely, the smaller the order value, the larger the grid size will be. Note that there is an inherent trade-off involved: a small grid will lower the cost of FFTs or MSM direct sum, but a larger order parameter will increase the cost of interpolating charge/fields to/from the grid.

The PPPM order parameter may be reset by LAMMPS when it sets up the FFT grid if the implied grid stencil extends beyond the grid cells owned by neighboring processors. Typically this will only occur when small problems are run on large numbers of processors. A warning will be generated indicating the order parameter is being reduced to allow LAMMPS to run the problem. Automatic adjustment of the order parameter is not supported in MSM.

The `order/disp` keyword determines how many grid spacings an atom’s dispersion term extends when it is mapped to the grid in kspace style `pppm/disp`. It has the same meaning as the `order` setting for Coulombics.
The **overlap** keyword can be used in conjunction with the **minorder** keyword with the PPPM styles to adjust the amount of communication that occurs when values on the FFT grid are exchanged between processors. This communication is distinct from the communication inherent in the parallel FFTs themselves, and is required because processors interpolate charge and field values using grid point values owned by neighboring processors (i.e., ghost point communication). If the **overlap** keyword is set to **yes** then this communication is allowed to extend beyond nearest-neighbor processors, e.g., when using lots of processors on a small problem. If it is set to **no** then the communication will be limited to nearest-neighbor processors and the **order** setting will be reduced if necessary, as explained by the **minorder** keyword discussion. The **overlap** keyword is always set to **yes** in MSM.

The **pressure/scalar** keyword applies only to MSM. If this option is turned on, only the scalar pressure (i.e. \(\frac{P_{xx} + P_{yy} + P_{zz}}{3.0}\)) will be computed, which can be used, for example, to run an isotropic barostat. Computing the full pressure tensor with MSM is expensive, and this option provides a faster alternative. The scalar pressure is computed using a relationship between the Coulombic energy and pressure (Hummer) instead of using the virial equation. This option cannot be used to access individual components of the pressure tensor, to compute per-atom virial, or with suffix kspace/pair styles of MSM, like OMP or GPU.

The **scafacos** keyword is used for settings that are passed to the ScaFaCoS library when using **kspace_style scafacos**. The **tolerance** option affects how the accuracy specified with the **kspace_style** command is interpreted by ScaFaCoS. The following values may be used:

- energy = absolute accuracy in total Coulombic energy
- energy_rel = relative accuracy in total Coulombic energy
- potential = absolute accuracy in total Coulombic potential
- potential_rel = relative accuracy in total Coulombic potential
- field = absolute accuracy in electric field
- field_rel = relative accuracy in electric field

The values with suffix _rel indicate the tolerance is a relative tolerance; the other values impose an absolute tolerance on the given quantity. Absolute tolerance in this case means, that for a given quantity \(q\) and a given absolute tolerance of \(t_a\) the result should be between \(q-t_a\) and \(q+t_a\). For a relative tolerance \(t_r\) the relative error should not be greater than \(t_r\), i.e., \(\text{abs}(1 - (\text{result}/q)) < t_r\). As a consequence of this, the tolerance type should be checked, when performing computations with a high absolute field/energy. E.g., if the total energy in the system is 1000000.0 an absolute tolerance of 1e-3 would mean that the result has to be between 999999.999 and 1000000.001, which would be equivalent to a relative tolerance of 1e-9.

The energy and energy_rel values, set a tolerance based on the total Coulombic energy of the system. The potential and potential_rel set a tolerance based on the per-atom Coulombic energy. The field and field_rel tolerance types set a tolerance based on the electric field values computed by ScaFaCoS. Since per-atom forces are derived from the per-atom electric field, this effectively sets a tolerance on the forces, similar to other LAMMPS KSpace styles, as explained on the **kspace_style** doc page.

Note that not all ScaFaCoS solvers support all tolerance types. These are the allowed values for each method:

- fmm = energy and energy_rel
- p2nfft = field (1d-, 2d-, 3d-periodic systems) or potential (0d-periodic)
- p3m = field
- ewald = field
- direct = has no tolerance tuning
If the tolerance type is not changed, the default values for the tolerance type are the first values in the above list, e.g. energy is the default tolerance type for the fmm solver.

The fmm_tuning option is only relevant when using the FMM method. It activates (value=1) or deactivates (value=0) an internal tuning mechanism for the FMM solver. The tuning operation runs sequentially and can be very time-consuming. Usually it is not needed for systems with a homogeneous charge distribution. The default for this option is therefore 0. The FMM internal tuning is performed once, when the solver is set up.

The slab keyword allows an Ewald or PPPM solver to be used for a systems that are periodic in x,y but non-periodic in z - a boundary setting of “boundary p p f”. This is done by treating the system as if it were periodic in z, but inserting empty volume between atom slabs and removing dipole inter-slab interactions so that slab-slab interactions are effectively turned off. The volfactor value sets the ratio of the extended dimension in z divided by the actual dimension in z. The recommended value is 3.0. A larger value is inefficient; a smaller value introduces unwanted slab-slab interactions. The use of fixed boundaries in z means that the user must prevent particle migration beyond the initial z-bounds, typically by providing a wall-style fix. The methodology behind the slab option is explained in the paper by (Yeh). The slab option is also extended to non-neutral systems (Ballenegger).

An alternative slab option can be invoked with the nozforce keyword in lieu of the volfactor. This turns off all kspace forces in the z direction. The nozforce option is not supported by MSM. For MSM, any combination of periodic, non-periodic, or shrink-wrapped boundaries can be set using boundary (the slab approximation in not needed). The slab keyword is not currently supported by Ewald or PPPM when using a triclinic simulation cell. The slab correction has also been extended to point dipole interactions (Klapp) in kspace_style ewald/disp, ewald/dipole, and pppm/dipole.

Note: If you wish to apply an electric field in the Z-direction, in conjunction with the slab keyword, you should do it by adding explicit charged particles to the +/- Z surfaces. If you do it via the fix efield command, it will not give the correct dielectric constant due to the Yeh/Berkowitz (Yeh) correction not being compatible with how fix efield works.

The force/disp/real and force/disp/kspace keywords set the force accuracy for the real and reciprocal space computations for the dispersion part of pppm/disp. As shown in (Isele-Holder), optimal performance and accuracy in the results is obtained when these values are different.

The disp/auto option controls whether the pppm/disp is allowed to generate PPPM parameters automatically. If set to no, parameters have to be specified using the gewald/disp, mesh/disp, force/disp/real or force/disp/kspace keywords, or the code will stop with an error message. When this option is set to yes, the error message will not appear and the simulation will start. For a typical application, using the automatic parameter generation will provide simulations that are either inaccurate or slow. Using this option is thus not recommended. For guidelines on how to obtain good parameters, see the Howto dispersion doc page.

16.64.4 Restrictions

none
16.64.5 Related commands

kspace_style, boundary

16.64.6 Default

The option defaults are mesh = mesh/disp = 0.0, order = order/disp = 5 (PPPM), order = 10 (MSM), minorder = 2, overlap = yes, force = -1.0, gewald = gewald/disp = 0.0, slab = 1.0, compute = yes, cutoff/adjust = yes (MSM), pressure/scalar = yes (MSM), fftbench = no (PPPM), diff = ik (PPPM), mix/disp = pair, force/disps = real = -1.0, force/disp/kspace = -1.0, split = 0, tol = 1.0e-6, and disp/auto = no. For pppm/intel, order = order/disp = 7. For scafacos settings, the scafacos tolerance option depends on the method chosen, as documented above. The scafacos fmm_tuning default = 0.

16.65.3 Description

Define a long-range solver for LAMMPS to use each timestep to compute long-range Coulombic interactions or long-range $1/r^6$ interactions. Most of the long-range solvers perform their computation in K-space, hence the name of this command.

When such a solver is used in conjunction with an appropriate pair style, the cutoff for Coulombic or $1/r^N$ interactions is effectively infinite. If the Coulombic case, this means each charge in the system interacts with charges in an infinite array of periodic images of the simulation domain.

Note that using a long-range solver requires use of a matching pair style to perform consistent short-range pairwise calculations. This means that the name of the pair style contains a matching keyword to the name of the KSpace style, as in this table:

<table>
<thead>
<tr>
<th>Pair style</th>
<th>KSpace style</th>

<td>dipole</td>
</tr>
</tbody>
</table>

The ewald style performs a standard Ewald summation as described in any solid-state physics text.

The ewald/disp style adds a long-range dispersion sum option for $1/r^6$ potentials and is useful for simulation of interfaces (Veld). It also performs standard Coulombic Ewald summations, but in a more efficient manner than the ewald style. The $1/r^6$ capability means that Lennard-Jones or Buckingham potentials can be used without a cutoff, i.e. they become full long-range potentials.

The ewald/disp/dipole style can also be used with point-dipoles, see (Toukmaji).

The ewald/dipole style adds long-range standard Ewald summations for dipole-dipole interactions, see (Toukmaji).
The *ewald/dipole/spin* style adds long-range standard Ewald summations for magnetic dipole-dipole interactions between magnetic spins.

The *pppm* style invokes a particle-particle particle-mesh solver *(Hockney)* which maps atom charge to a 3d mesh, uses 3d FFTs to solve Poisson’s equation on the mesh, then interpolates electric fields on the mesh points back to the atoms. It is closely related to the particle-mesh Ewald technique (PME) *(Darden)* used in AMBER and CHARMM. The cost of traditional Ewald summation scales as \( N^2 \) where \( N \) is the number of atoms in the system. The PPPM solver scales as \( N \log N \) due to the FFTs, so it is almost always a faster choice *(Pollock)*.

The *pppm/cg* style is identical to the *pppm* style except that it has an optimization for systems where most particles are uncharged. Similarly the *msm/cg* style implements the same optimization for *msm*. The optional *smallq* argument defines the cutoff for the absolute charge value which determines whether a particle is considered charged or not. Its default value is 1.0e-5.

The *pppm/dipole* style invokes a particle-particle particle-mesh solver for dipole-dipole interactions, following the method of *(Cerda)*.

The *pppm/dipole/spin* style invokes a particle-particle particle-mesh solver for magnetic dipole-dipole interactions between magnetic spins.

The *pppm/tip4p* style is identical to the *pppm* style except that it adds a charge at the massless fourth site in each TIP4P water molecule. It should be used with *pair styles* with a *tip4p/long* in their style name.

The *pppm/stagger* style performs calculations using two different meshes, one shifted slightly with respect to the other. This can reduce force aliasing errors and increase the accuracy of the method for a given mesh size. Or a coarser mesh can be used for the same target accuracy, which saves CPU time. However, there is a trade-off since FFTs on two meshes are now performed which increases the computation required. See *(Cerutti), (Neelov), and (Hockney)* for details of the method.

For high relative accuracy, using staggered PPPM allows the mesh size to be reduced by a factor of 2 in each dimension as compared to regular PPPM (for the same target accuracy). This can give up to a 4x speedup in the KSpace time (8x less mesh points, 2x more expensive). However, for low relative accuracy, the staggered PPPM mesh size may be essentially the same as for regular PPPM, which means the method will be up to 2x slower in the KSpace time (simply 2x more expensive). For more details and timings, see the *Speed tips* doc page.

**Note:** Using *pppm/stagger* may not give the same increase in the accuracy of energy and pressure as it does in forces, so some caution must be used if energy and/or pressure are quantities of interest, such as when using a barostat.

The *pppm/disp* and *pppm/disp/tip4p* styles add a mesh-based long-range dispersion sum option for 1/r^6 potentials *(Isele-Holder)*, similar to the *ewald/disp* style. The 1/r^6 capability means that Lennard-Jones or Buckingham potentials can be used without a cutoff, i.e. they become full long-range potentials.

For these styles, you will possibly want to adjust the default choice of parameters by using the *kspace_modify* command. This can be done by either choosing the Ewald and grid parameters, or by specifying separate accuracies for the real and kspace calculations. When not making any settings, the simulation will stop with an error message. Further information on the influence of the parameters and how to choose them is described in *(Isele-Holder), (Isele-Holder2)* and the *Howto dispersion* doc page.

**Note:** All of the PPPM styles can be used with single-precision FFTs by using the compiler switch -DFFT_SINGLE for the FFT_INC setting in your low-level Makefile. This setting also changes some of the PPPM operations (e.g. mapping charge to mesh and interpolating electric fields to particles) to be performed in single precision. This option...
can speed-up long-range calculations, particularly in parallel or on GPUs. The use of the `-DFFT_SINGLE` flag is discussed on the Build settings doc page. MSM does not currently support the `-DFFT_SINGLE` compiler switch.

The electrode styles add methods that are required for the constant potential method implemented in fix electrode/*.

The styles ewald/electrode, pppm/electrode and pppm/electrode/intel are available. These styles do not support the kspace_modify slab nozforce command.

The msm style invokes a multi-level summation method MSM solver, (Hardy) or (Hardy2), which maps atom charge to a 3d mesh, and uses a multi-level hierarchy of coarser and coarser meshes on which direct Coulomb solvers are done. This method does not use FFTs and scales as \(N\). It may therefore be faster than the other K-space solvers for relatively large problems when running on large core counts. MSM can also be used for non-periodic boundary conditions and for mixed periodic and non-periodic boundaries.

MSM is most competitive versus Ewald and PPPM when only relatively low accuracy forces, about 1e-4 relative error or less accurate, are needed. Note that use of a larger Coulombic cutoff (i.e. 15 angstroms instead of 10 angstroms) provides better MSM accuracy for both the real space and grid computed forces.

Currently calculation of the full pressure tensor in MSM is expensive. Using the kspace_modify pressure/scalar yes command provides a less expensive way to compute the scalar pressure \((P_{xx} + P_{yy} + P_{zz})/3.0\). The scalar pressure can be used, for example, to run an isotropic barostat. If the full pressure tensor is needed, then calculating the pressure at every timestep or using a fixed pressure simulation with MSM will cause the code to run slower.

The scafacos style is a wrapper on the ScaFaCoS Coulomb solver library which provides a variety of solver methods which can be used with LAMMPS. The paper by (Sutman) gives an overview of ScaFaCoS.

ScaFaCoS was developed by a consortium of German research facilities with a BMBF (German Ministry of Science and Education) funded project in 2009-2012. Participants of the consortium were the Universities of Bonn, Chemnitz, Stuttgart, and Wuppertal as well as the Forschungszentrum Juelich.

The library is available for download at “http://scafacos.de” or can be cloned from the git-repository “https://github.com/scafacos/scafacos.git”.

In order to use this KSpace style, you must download and build the ScaFaCoS library, then build LAMMPS with the SCAFACOS package installed package which links LAMMPS to the ScaFaCoS library. See details on this page.

Note: Unlike other KSpace solvers in LAMMPS, ScaFaCoS computes all Coulombic interactions, both short- and long-range. Thus you should NOT use a Coulombic pair style when using kspace_style scafacos. This also means the total Coulombic energy (short- and long-range) will be tallied for thermodynamic output command as part of the elong keyword; the ecoul keyword will be zero.

Note: See the current restriction below about use of ScaFaCoS in LAMMPS with molecular charged systems or the TIP4P water model.

The specified method determines which ScaFaCoS algorithm is used. These are the ScaFaCoS methods currently available from LAMMPS:

- `fmm` = Fast Multi-Pole method
- `p2nfft` = FFT-based Coulomb solver
- `ewald` = Ewald summation
LAMMPS Documentation, Release patch 23Jun2022

- **direct** = direct $O(N^2)$ summation
- **p3m** = PPPM

We plan to support additional ScaFaCoS solvers from LAMMPS in the future. For an overview of the included solvers, refer to [Sutmann](#).

The specified accuracy is similar to the accuracy setting for other LAMMPS KSpace styles, but is passed to ScaFaCoS, which can interpret it in different ways for different methods it supports. Within the ScaFaCoS library the accuracy is treated as a tolerance level (either absolute or relative) for the chosen quantity, where the quantity can be either the Coulomb field values, the per-atom Coulombic energy or the total Coulombic energy. To select from these options, see the `kspace_modify scafacos accuracy` doc page.

The `kspace_modify scafacos` command also explains other ScaFaCoS options currently exposed to LAMMPS.

---

The specified accuracy determines the relative RMS error in per-atom forces calculated by the long-range solver. It is set as a dimensionless number, relative to the force that two unit point charges (e.g. 2 monovalent ions) exert on each other at a distance of 1 Angstrom. This reference value was chosen as representative of the magnitude of electrostatic forces in atomic systems. Thus an accuracy value of $1.0e^{-4}$ means that the RMS error will be a factor of 10000 smaller than the reference force.

The accuracy setting is used in conjunction with the pairwise cutoff to determine the number of K-space vectors for style `ewald` or the grid size for style `pppm` or `msm`.

Note that style `pppm` only computes the grid size at the beginning of a simulation, so if the length or triclinic tilt of the simulation cell increases dramatically during the course of the simulation, the accuracy of the simulation may degrade. Likewise, if the `kspace_modify slab` option is used with shrink-wrap boundaries in the z-dimension, and the box size changes dramatically in z. For example, for a triclinic system with all three tilt factors set to the maximum limit, the PPPM grid should be increased roughly by a factor of 1.5 in the y direction and 2.0 in the z direction as compared to the same system using a cubic orthogonal simulation cell. One way to handle this issue if you have a long simulation where the box size changes dramatically, is to break it into shorter simulations (multiple run commands). This works because the grid size is re-computed at the beginning of each run. Another way to ensure the described accuracy requirement is met is to run a short simulation at the maximum expected tilt or length, note the required grid size, and then use the `kspace_modify mesh` command to manually set the PPPM grid size to this value for the long run. The simulation then will be “too accurate” for some portion of the run.

RMS force errors in real space for `ewald` and `pppm` are estimated using equation 18 of [Kolafa](#), which is also referenced as equation 9 of [Petersen](#). RMS force errors in K-space for `ewald` are estimated using equation 11 of [Petersen](#), which is similar to equation 32 of [Kolafa](#). RMS force errors in K-space for `pppm` are estimated using equation 38 of [Deserno](#). RMS force errors for `msm` are estimated using ideas from chapter 3 of [Hardy](#), with equation 3.197 of particular note. When using `msm` with non-periodic boundary conditions, it is expected that the error estimation will be too pessimistic. RMS force errors for dipoles when using `ewald/disp` or `ewald/dipole` are estimated using equations 33 and 46 of [Wang](#). The RMS force errors for `pppm/dipole` are estimated using the equations in [Cerda](#).

See the `kspace_modify` command for additional options of the K-space solvers that can be set, including a `force` option for setting an absolute RMS error in forces, as opposed to a relative RMS error.

---

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.
See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

**Note:** For the GPU package, the *pppm/gpu* style performs charge assignment and force interpolation calculations on the GPU. These processes are performed either in single or double precision, depending on whether the `-DFFT_SINGLE` setting was specified in your low-level Makefile, as discussed above. The FFTs themselves are still calculated on the CPU. If *pppm/gpu* is used with a GPU-enabled pair style, part of the PPPM calculation can be performed concurrently on the GPU while other calculations for non-bonded and bonded force calculation are performed on the CPU.

**Note:** For the KOKKOS package, the *pppm/kk* style performs charge assignment and force interpolation calculations, along with the FFTs themselves, on the GPU or (optionally) threaded on the CPU when using OpenMP and FFTW3.

### 16.65.4 Restrictions

Note that the long-range electrostatic solvers in LAMMPS assume conducting metal (tinfoil) boundary conditions for both charge and dipole interactions. Vacuum boundary conditions are not currently supported.

The *ewald/disP, ewald, pppm, and msM* styles support non-orthogonal (triclinic symmetry) simulation boxes. However, triclinic simulation cells may not yet be supported by all suffix versions of these styles.

Most of the base kspace styles are part of the KSPACE package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

The *msM/dielectric and pppm/dielectric* kspace styles are part of the DIELECTRIC package. They are only enabled if LAMMPS was built with that package and the KSPACE package. See the *Build package* page for more info.

For MSM, a simulation must be 3d and one can use any combination of periodic, non-periodic, but not shrink-wrapped boundaries (specified using the *boundary* command).

For Ewald and PPPM, a simulation must be 3d and periodic in all dimensions. The only exception is if the slab option is set with *kspace_modify*, in which case the xy dimensions must be periodic and the z dimension must be non-periodic.

The scafacos KSpace style will only be enabled if LAMMPS is built with the SCAFACOS package. See the *Build package* doc page for more info.

The use of ScaFaCos in LAMMPS does not yet support molecular charged systems where the short-range Coulombic interactions between atoms in the same bond/angle/dihedral are weighted by the *special_bonds* command. Likewise it does not support the “TIP4P water style” where a fictitious charge site is introduced in each water molecule. Finally, the methods *p3m* and *ewald* do not support computing the virial, so this contribution is not included.

x,y,z = fractional coords of a basis atom (0 <= x,y,z < 1)

## 16.67.2 Examples

```plaintext
lattice fcc 3.52
lattice hex 0.85
lattice sq 0.8 origin 0.0 0.5 0.0 orient x 1 1 0 orient y -1 1 0
lattice custom 3.52 a1 1.0 0.0 0.0 a2 0.5 1.0 0.0 a3 0.0 0.0 0.5 &
basis 0.0 0.0 0.0 basis 0.5 0.5 0.5
lattice none 2.0
```

## 16.67.3 Description

Define a lattice for use by other commands. In LAMMPS, a lattice is simply a set of points in space, determined by a unit cell with basis atoms, that is replicated infinitely in all dimensions. The arguments of the lattice command can be used to define a wide variety of crystallographic lattices.

A lattice is used by LAMMPS in two ways. First, the `create_atoms` command creates atoms on the lattice points inside the simulation box. Note that the `create_atoms` command allows different atom types to be assigned to different basis atoms of the lattice. Second, the lattice spacing in the x,y,z dimensions implied by the lattice, can be used by other commands as distance units (e.g. `create_box`, `region` and `velocity`), which are often convenient to use when the underlying problem geometry is atoms on a lattice.

The lattice style must be consistent with the dimension of the simulation - see the `dimension` command. Styles `sc` or `bcc` or `fcc` or `hcp` or `diamond` are for 3d problems. Styles `sq` or `sq2` or `hex` are for 2d problems. Style `custom` can be used for either 2d or 3d problems.

A lattice consists of a unit cell, a set of basis atoms within that cell, and a set of transformation parameters (scale, origin, orient) that map the unit cell into the simulation box. The vectors a1,a2,a3 are the edge vectors of the unit cell. This is the nomenclature for “primitive” vectors in solid-state crystallography, but in LAMMPS the unit cell they determine does not have to be a “primitive cell” of minimum volume.

Note that the lattice command can be used multiple times in an input script. Each time it is invoked, the lattice attributes are re-defined and are used for all subsequent commands (that use lattice attributes). For example, a sequence of lattice, `region`, and `create_atoms` commands can be repeated multiple times to build a poly-crystalline model with different geometric regions populated with atoms in different lattice orientations.

A lattice of style `none` does not define a unit cell and basis set, so it cannot be used with the `create_atoms` command. However it does define a lattice spacing via the specified scale parameter. As explained above the lattice spacings in x,y,z can be used by other commands as distance units. No additional keyword/value pairs can be specified for the `none` style. By default, a “lattice none 1.0” is defined, which means the lattice spacing is the same as one distance unit, as defined by the `units` command.

Lattices of style `sc`, `fcc`, `bcc`, and `diamond` are 3d lattices that define a cubic unit cell with edge length = 1.0. This means a1 = 1 0 0, a2 = 0 1 0, and a3 = 0 0 1. Style `hcp` has a1 = 1 0 0, a2 = 0 sqrt(3) 0, and a3 = 0 0 sqrt(8/3). The placement of the basis atoms within the unit cell are described in any solid-state physics text. A `sc` lattice has 1 basis atom at the lower-left-bottom corner of the cube. A `bcc` lattice has 2 basis atoms, one at the corner and one at the center of the cube. A `fcc` lattice has 4 basis atoms, one at the corner and 3 at the cube face centers. A `hcp` lattice has 4 basis atoms, two in the z = 0 plane and 2 in the z = 0.5 plane. A `diamond` lattice has 8 basis atoms.

Lattices of style `sq` and `sq2` are 2d lattices that define a square unit cell with edge length = 1.0. This means a1 = 1 0 0 and a2 = 0 1 0. A `sq` lattice has 1 basis atom at the lower-left corner of the square. A `sq2` lattice has 2 basis atoms, one
A hex style is also a 2d lattice, but the unit cell is rectangular, with \( a_1 = 1 \ 0 \ 0 \) and \( a_2 = 0 \ \sqrt{3} \ 0 \). It has 2 basis atoms, one at the corner and one at the center of the rectangle.

A lattice of style custom allows you to specify \( a_1, a_2, a_3 \), and a list of basis atoms to put in the unit cell. By default, \( a_1 \) and \( a_2 \) and \( a_3 \) are 3 orthogonal unit vectors (edges of a unit cube). But you can specify them to be of any length and non-orthogonal to each other, so that they describe a tilted parallelepiped. Via the basis keyword you add atoms, one at a time, to the unit cell. Its arguments are fractional coordinates (0.0 <= x,y,z < 1.0). The position vector \( x \) of a basis atom within the unit cell is thus a linear combination of the unit cell’s 3 edge vectors, i.e. \( x = b_x a_1 + b_y a_2 + b_z a_3 \), where \( b_x, b_y, b_z \) are the 3 values specified for the basis keyword.

This sub-section discusses the arguments that determine how the idealized unit cell is transformed into a lattice of points within the simulation box.

The scale argument determines how the size of the unit cell will be scaled when mapping it into the simulation box. I.e. it determines a multiplicative factor to apply to the unit cell, to convert it to a lattice of the desired size and distance units in the simulation box. The meaning of the scale argument depends on the units being used in your simulation.

For all unit styles except \( lj \), the scale argument is specified in the distance units defined by the unit style. For example, in real or metal units, if the unit cell is a unit cube with edge length 1.0, specifying scale = 3.52 would create a cubic lattice with a spacing of 3.52 Angstroms. In cgs units, the spacing would be 3.52 cm.

For unit style \( lj \), the scale argument is the Lennard-Jones reduced density, typically written as \( \rho^* \). LAMMPS converts this value into the multiplicative factor via the formula “\( \text{factor}^{\text{dim}} = \rho/\rho^* \)”, where \( \rho = N/V \) with \( V \) = the volume of the lattice unit cell and \( N \) = the number of basis atoms in the unit cell (described below), and \( \text{dim} = 2 \) or \( 3 \) for the dimensionality of the simulation. Effectively, this means that if LJ particles of size \( \sigma = 1.0 \) are used in the simulation, the lattice of particles will be at the desired reduced density.

The origin option specifies how the unit cell will be shifted or translated when mapping it into the simulation box. The x,y,z values are fractional values (0.0 <= x,y,z < 1.0) meaning shift the lattice by a fraction of the lattice spacing in each dimension. The meaning of “lattice spacing” is discussed below.

The orient option specifies how the unit cell will be rotated when mapping it into the simulation box. The dim argument is one of the 3 coordinate axes in the simulation box. The other 3 arguments are the crystallographic direction in the lattice that you want to orient along that axis, specified as integers. E.g. “orient x 2 1 0” means the x-axis in the simulation box will be the [210] lattice direction, and similarly for y and z. The 3 lattice directions you specify do not have to be unit vectors, but they must be mutually orthogonal and obey the right-hand rule, i.e. (X cross Y) points in the Z direction.

Note: The preceding paragraph describing lattice directions is only valid for orthogonal cubic unit cells (or square in 2d). If you are using a hcp or hex lattice or the more general lattice style custom with non-orthogonal \( a_1,a_2,a_3 \) vectors, then you should think of the 3 orient vectors as creating a 3x3 rotation matrix which is applied to \( a_1,a_2,a_3 \) to rotate the original unit cell to a new orientation in the simulation box.

Several LAMMPS commands have the option to use distance units that are inferred from “lattice spacings” in the x,y,z box directions. E.g. the region command can create a block of size 10x20x20, where 10 means 10 lattice spacings in the x direction.

Note: Though they are called lattice spacings, all the commands that have a “units lattice” option, simply use the 3 values as scale factors on the distance units defined by the units command. Thus if you do not like the lattice spacings computed by LAMMPS (e.g. for a non-orthogonal or rotated unit cell), you can define the 3 values to be whatever you wish, via the spacing option.
If the `spacing` option is not specified, the lattice spacings are computed by LAMMPS in the following way. A unit cell of the lattice is mapped into the simulation box (scaled and rotated), so that it now has (perhaps) a modified size and orientation. The lattice spacing in X is defined as the difference between the min/max extent of the x coordinates of the 8 corner points of the modified unit cell (4 in 2d). Similarly, the Y and Z lattice spacings are defined as the difference in the min/max of the y and z coordinates.

Note that if the unit cell is orthogonal with axis-aligned edges (no rotation via the `orient` keyword), then the lattice spacings in each dimension are simply the scale factor (described above) multiplied by the length of a1,a2,a3. Thus a `hex` style lattice with a scale factor of 3.0 Angstroms, would have a lattice spacing of 3.0 in x and $3\sqrt{3.0}$ in y.

Note: For non-orthogonal unit cells and/or when a rotation is applied via the `orient` keyword, then the lattice spacings computed by LAMMPS are typically less intuitive. In particular, in these cases, there is no guarantee that a particular lattice spacing is an integer multiple of the periodicity of the lattice in that direction. Thus, if you create an orthogonal periodic simulation box whose size in a dimension is a multiple of the lattice spacing, and then fill it with atoms via the `create_atoms` command, you will NOT necessarily create a periodic system. I.e. atoms may overlap incorrectly at the faces of the simulation box.

The `spacing` option sets the 3 lattice spacings directly. All must be non-zero (use 1.0 for dz in a 2d simulation). The specified values are multiplied by the multiplicative factor described above that is associated with the scale factor. Thus a spacing of 1.0 means one unit cell edge length independent of the scale factor. As mentioned above, this option can be useful if the spacings LAMMPS computes are inconvenient to use in subsequent commands, which can be the case for non-orthogonal or rotated lattices.

Note that whenever the lattice command is used, the values of the lattice spacings LAMMPS calculates are printed out. Thus their effect in commands that use the spacings should be decipherable.

Example commands for generating a Wurtzite crystal. The lattice constants approximate those of CdSe. The $\sqrt{3} \times 1$ orthorhombic supercell is used with the x, y, and z directions oriented along $[\bar{1}2\bar{3}0]$, $[10\bar{1}0]$, and $[0001]$, respectively.

```plaintext

```
16.67.4 Restrictions

The $a_1,a_2,a_3,basis$ keywords can only be used with style custom.

16.67.5 Related commands

dimension, create_atoms, region

16.67.6 Default

```
lattice none 1.0
```

For other lattice styles, the option defaults are origin = 0.0 0.0 0.0, orient = x 1 0 0, orient = y 0 1 0, orient = z 0 0 1, $a_1 = 1 0 0$, $a_2 = 0 1 0$, and $a_3 = 0 0 1$.

16.68 log command

16.68.1 Syntax

```
log file keyword
```

- file = name of new logfile
- keyword = append if output should be appended to logfile (optional)

16.68.2 Examples

```
log log.equil
log log.equil append
```
16.68.3 Description

This command closes the current LAMMPS log file, opens a new file with the specified name, and begins logging information to it. If the specified file name is none, then no new log file is opened. If the optional keyword append is specified, then output will be appended to an existing log file, instead of overwriting it.

If multiple processor partitions are being used, the file name should be a variable, so that different processors do not attempt to write to the same log file.

The file “log.lammps” is the default log file for a LAMMPS run. The name of the initial log file can also be set by the -log command-line switch.

16.68.4 Restrictions

none

16.68.5 Related commands

none

16.68.6 Default

The default LAMMPS log file is named log.lammps

16.69 mass command

16.69.1 Syntax

```
mass I value
```

- I = atom type (see asterisk form below)
- value = mass

16.69.2 Examples

```
mass 1 1.0
mass * 62.5
mass 2* 62.5
```
16.69.3 Description

Set the mass for all atoms of one or more atom types. Per-type mass values can also be set in the `read_data` data file using the “Masses” keyword. See the `units` command for what mass units to use.

The I index can be specified in one of two ways. An explicit numeric value can be used, as in the first example above. Or a wild-card asterisk can be used to set the mass for multiple atom types. This takes the form “*” or “*n” or “n*” or “m*n”. If \( N \) = the number of atom types, then an asterisk with no numeric values means all types from 1 to \( N \). A leading asterisk means all types from 1 to \( n \) (inclusive). A trailing asterisk means all types from \( n \) to \( N \) (inclusive). A middle asterisk means all types from \( m \) to \( n \) (inclusive).

A line in a `data file` that follows the “Masses” keyword specifies mass using the same format as the arguments of the mass command in an input script, except that no wild-card asterisk can be used. For example, under the “Masses” section of a data file, the line that corresponds to the first example above would be listed as

```
1 1.0
```

Note that the mass command can only be used if the `atom style` requires per-type atom mass to be set. Currently, all but the `sphere` and `ellipsoid` and `peri` styles do. They require mass to be set for individual particles, not types. Per-atom masses are defined in the data file read by the `read_data` command, or set to default values by the `create_atoms` command. Per-atom masses can also be set to new values by the `set mass` or `set density` commands.

Also note that `pair_style eam` and `pair_style bop` commands define the masses of atom types in their respective potential files, in which case the mass command is normally not used.

If you define a `hybrid atom style` which includes one (or more) sub-styles which require per-type mass and one (or more) sub-styles which require per-atom mass, then you must define both. However, in this case the per-type mass will be ignored; only the per-atom mass will be used by LAMMPS.

16.69.4 Restrictions

This command must come after the simulation box is defined by a `read_data`, `read_restart`, or `create_box` command.

All masses must be defined before a simulation is run. They must also all be defined before a `velocity` or `fix shake` command is used.

The mass assigned to any type or atom must be \( > 0.0 \).

  infile in.aimd.engine extra "-log log.aimd.engine.plugin" &
  command "run 5"
```

16.70.3 Description

This command implements two high-level operations within LAMMPS to use the MDI Library <https://molssi-mdi.github.io/MDI_Library/html/index.html> for coupling to other codes in a client/server protocol.

The *engine* mode enables LAMMPS to act as an MDI engine (server), responding to requests from an MDI driver (client) code.

The *plugin* mode enables LAMMPS to act as an MDI driver (client), and load the MDI engine (server) code as a library plugin. In this case the MDI engine is a library plugin. It can also be a stand-alone code, launched separately from LAMMPS, in which case the mdi plugin command is not used.

See the Howto MDI doc page for a discussion of all the different ways 2 or more codes can interact via MDI.

The examples/mdi directory has examples which use LAMMPS in 4 different modes: as a driver using an engine as either a stand-alone code or as a plugin, and as an engine operating as either a stand-alone code or as a plugin. The README file in that directory shows how to launch and couple codes for all the 4 usage modes, and so they communicate via the MDI library using either MPI or sockets.

The *mdi engine* command is used to make LAMMPS operate as an MDI engine. It is typically used in an input script after LAMMPS has setup the system it is going to model consistent with what the driver code expects. Depending on when the driver code tells the LAMMPS engine to exit, other commands can be executed after this command, but typically it is used at the end of a LAMMPS input script.

To act as an MDI engine operating as an MD code (or surrogate QM code), this is the list of standard MDI commands issued by a driver code which LAMMPS currently recognizes. Using standard commands defined by the MDI library
means that a driver code can work interchangeably with LAMMPS or other MD codes or with QM codes which support the MDI standard. See more details about these commands in the MDI library documentation.

These commands are valid at the @DEFAULT node defined by MDI. Commands that start with “>” mean the driver is sending information to LAMMPS. Commands that start with “<” are requests by the driver for LAMMPS to send it information. Commands that start with an alphabetic letter perform actions. Commands that start with “@” are MDI “node” commands, which are described further below.

<table>
<thead>
<tr>
<th>Command name</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt;CELL or &lt;CELL</td>
<td>Send/request 3 simulation box edge vectors (9 values)</td>
</tr>
<tr>
<td>&gt;CELL_DISPL or &lt;CELL_DISPL</td>
<td>Send/request displacement of the simulation box from the origin (3 values)</td>
</tr>
<tr>
<td>&gt;CHARGES or &lt;CHARGES</td>
<td>Send/request charge on each atom (N values)</td>
</tr>
<tr>
<td>&gt;COORDS or &lt;COORDS</td>
<td>Send/request coordinates of each atom (3N values)</td>
</tr>
<tr>
<td>&lt;ENERGY</td>
<td>Request total energy (potential + kinetic) of the system (1 value)</td>
</tr>
<tr>
<td>&gt;FORCES or &lt;FORCES</td>
<td>Send/request forces on each atom (3N values)</td>
</tr>
<tr>
<td>&gt;+FORCES</td>
<td>Send forces to add to each atom (3N values)</td>
</tr>
<tr>
<td>&lt;LABELS</td>
<td>Request string label of each atom (N values)</td>
</tr>
<tr>
<td>&lt;MASSES</td>
<td>Request mass of each atom (N values)</td>

<tr>
<td>&lt;STRESS</td>
<td>Request stress tensor (virial) of the system (6 values)</td>
</tr>
<tr>
<td>&gt;TOLERANCE</td>
<td>Send 4 tolerance parameters for next MD minimization via OPTG command</td>
</tr>
<tr>
<td>&gt;TYPES or &lt;TYPES</td>
<td>Send/request the numeric type of each atom (N values)</td>
</tr>
<tr>
<td>&gt;VELOCITIES or &lt;VELOCITIES</td>
<td>Send/request the velocity of each atom (3N values)</td>
</tr>
<tr>
<td>@INIT_MD or @INIT_OPTG</td>
<td>Driver tells LAMMPS to start single-step dynamics or minimization (see below)</td>
</tr>
<tr>
<td>EXIT</td>
<td>Driver tells LAMMPS to exit engine mode</td>
</tr>
</tbody>
</table>

**Note:** The <ENERGY, <FORCES, <PE, and <STRESS commands trigger LAMMPS to compute atomic interactions for the current configuration of atoms and size/shape of the simulation box. I.e. LAMMPS invokes its pair, bond, angle, . . ., kspace styles. If the driver is updating the atom coordinates and/or box incrementally (as in an MD simulation which the driver is managing), then the LAMMPS engine will do the same, and only occasionally trigger neighbor list builds. If the change in atom positions is large (since the previous >COORDS command), then LAMMPS will do a more expensive operation to migrate atoms to new processors as needed and re-neighbor. If the >NATOMS or >TYPES commands have been sent (since the previous >COORDS command), then LAMMPS assumes the system is new and re-initializes an entirely new simulation.

The MD and OPTG commands perform an entire MD simulation or energy minimization (to convergence) with no communication from the driver until the simulation is complete. By contrast, the @INIT_MD and @INIT_OPTG commands allow the driver to communicate with the engine at each timestep of a dynamics run or iteration of a minimization; see more info below.
The MD command performs a simulation using the most recent >NSTEPS value. The OPTG command performs a minimization using the 4 convergence parameters from the most recent >TOLERANCE command. The 4 parameters sent are those used by the `minimize` command in LAMMPS: etol, ftol, maxiter, and maxeval.

The mdi engine command also implements the following custom MDI commands which are LAMMPS-specific. These commands are also valid at the @DEFAULT node defined by MDI:

- Command name
- Action
- >NBYTES
  - Send # of datums in a subsequent command (1 value)
- >COMMAND
  - Send a LAMMPS input script command as a string (Nbytes in length)
- >COMMANDS
  - Send multiple LAMMPS input script commands as a newline-separated string (Nbytes in length)
- >INFILE
  - Send filename of an input script to execute (filename Nbytes in length)
- <KE
  - Request kinetic energy of the system (1 value)

Note that other custom commands can easily be added if these are not sufficient to support what a user-written driver code needs. Code to support new commands can be added to the MDI package within LAMMPS, specifically to the src/MDI/mdi_engine.cpp file.

MDI also defines a standard mechanism for the driver to request that an MD engine (LAMMPS) perform a dynamics simulation one step at a time or an energy minimization one iteration at a time. This is so that the driver can (optionally) communicate with LAMMPS at intermediate points of the timestep or iteration by issuing MDI node commands which start with “@”.

To tell LAMMPS to run dynamics in single-step mode, the driver sends as @INIT_MD command followed by the these commands. The driver can interact with LAMMPS at 3 node locations within each timestep: @COORDS, @FORCES, @ENDSTEP:

- Command name
- Action
- @COORDS
  - Proceed to next @COORDS node = post-integrate location in LAMMPS timestep
- @FORCES
  - Proceed to next @FORCES node = post-force location in LAMMPS timestep
- @ENDSTEP
  - Proceed to next @ENDSTEP node = end-of-step location in LAMMPS timestep
- @DEFAULT
  - Exit MD simulation, return to @DEFAULT node
- EXIT
  - Driver tells LAMMPS to exit the MD simulation and engine mode
To tell LAMMPS to run an energy minimization in single-iteration mode. The driver can interact with LAMMPS at 2 node locations within each iteration of the minimizer: @COORDS, @FORCES:

- Command name
  - Action
- @COORDS
  - Proceed to next @COORDS node = min-pre-force location in LAMMPS min iteration
- @FORCES
  - Proceed to next @FORCES node = min-post-force location in LAMMPS min iteration
- @DEFAULT
  - Exit minimization, return to @DEFAULT node
- EXIT
  - Driver tells LAMMPS to exit the minimization and engine mode

While LAMMPS is at its @COORDS node, the following standard MDI commands are supported, as documented above: >COORDS or <COORDS, @COORDS, @FORCES, @ENDSTEP, @DEFAULT, EXIT.

While LAMMPS is at its @FORCES node, the following standard MDI commands are supported, as documented above: <COORDS, <ENERGY, >FORCES or >+FORCES or <FORCES, <KE, <PE, <STRESS, @COORDS, @FORCES, @ENDSTEP, @DEFAULT, EXIT.

While LAMMPS is at its @ENDSTEP node, the following standard MDI commands are supported, as documented above: <ENERGY, <FORCES, <KE, <PE, <STRESS, @COORDS, @FORCES, @ENDSTEP, @DEFAULT, EXIT.

The mdi plugin command is used to make LAMMPS operate as an MDI driver which loads an MDI engine as a plugin library. It is typically used in an input script after LAMMPS has setup the system it is going to model consistent with the engine code.

The name argument specifies which plugin library to load. A name like “lammps” is converted to a filename liblammps.so. The path for where this file is located is specified by the -plugin_path switch within the -mdi command-line switch, which is specified when LAMMPS is launched. See the examples/mdi/README files for examples of how this is done.

The mdi keyword is required and is used as the -mdi argument passed to the library when it is launched. The -role and -method settings are required. The -name setting can be anything you choose. MDI drivers and engines can query their names to verify they are values they expect.

The infile keyword is also required. It is the name of an input script which the engine will open and process. MDI will pass it as a command-line argument to the library when it is launched. The file typically contains settings that an MD or QM code will use for its subsequent calculations.

The extra keyword is optional. It contains additional command-line arguments which MDI will pass to the library when it is launched.

The command keyword is required. It specifies a LAMMPS input script command (as a single argument in quotes if it is multiple words). Once the plugin library is launched, LAMMPS will execute this command. Other previously-defined commands in the input script, such as the fix mdi/aimd command, should perform MDI communication with the engine, while the specified command executes. Note that if command is an include command, then it could specify a filename with multiple LAMMPS commands.

Note: When the single command is complete, LAMMPS will send an MDI EXIT command to the plugin engine and the plugin will be removed. The “mdi plugin” command will then exit and the next command (if any) in the LAMMPS
input script will be processed. A subsequent “mdi plugin” command could then load the same library plugin or a
different one if desired.

16.70.4 Restrictions

This command is part of the MDI package. It is only enabled if LAMMPS was built with that package. See the Build
package page for more info.

To use LAMMPS in conjunction with other MDI-enabled atomistic codes, the units command should be used to specify
real or metal units. This will ensure the correct unit conversions between LAMMPS and MDI units, which the other
codes will also perform in their preferred units.

LAMMPS can also be used as an MDI engine in other unit choices it supports, e.g. lj, but then no unit conversion is
performed.

```
min_modify dmax 0.2
min_modify integrator verlet tmax 4
```

16.71.3 Description

This command sets parameters that affect the energy minimization algorithms selected by the `min_style` command. The various settings may affect the convergence rate and overall number of force evaluations required by a minimization, so users can experiment with these parameters to tune their minimizations.

The `cg` and `sd` minimization styles have an outer iteration and an inner iteration which is steps along a one-dimensional line search in a particular search direction. The `dmax` parameter is how far any atom can move in a single line search in any dimension (x, y, or z). For the `quickmin` and `fire` minimization styles, the `dmax` setting is how far any atom can move in a single iteration (timestep). Thus a value of 0.1 in real `units` means no atom will move further than 0.1 Angstroms in a single outer iteration. This prevents highly overlapped atoms from being moved long distances (e.g. through another atom) due to large forces.

The choice of line search algorithm for the `cg` and `sd` minimization styles can be selected via the `line` keyword. The default `quadratic` line search algorithm starts out using the robust backtracking method described below. However, once the system gets close to a local minimum and the linesearch steps get small, so that the energy is approximately quadratic in the step length, it uses the estimated location of zero gradient as the linesearch step, provided the energy change is downhill. This becomes more efficient than backtracking for highly-converged relaxations. The `forcezero` line search algorithm is similar to `quadratic`. It may be more efficient than `quadratic` on some systems.

The backtracking search is robust and should always find a local energy minimum. However, it will “converge” when it can no longer reduce the energy of the system. Individual atom forces may still be larger than desired at this point, because the energy change is measured as the difference of two large values (energy before and energy after) and that difference may be smaller than machine epsilon even if atoms could move in the gradient direction to reduce forces further.

The choice of a norm can be modified for the min styles `cg`, `sd`, `quickmin`, `fire`, `fire/old`, `spin`, `spin/cg`, and `spin/lbfgs` using the `norm` keyword. The default `two` norm computes the 2-norm (Euclidean length) of the global force vector:

\[ \|\vec{F}\|_2 = \sqrt{\vec{F}_1^2 + \cdots + \vec{F}_N^2} \]

The `max` norm computes the length of the 3-vector force for each atom (2-norm), and takes the maximum value of those across all atoms:

\[ \|\vec{F}\|_{max} = \max\left(\|\vec{F}_1\|, \cdots, \|\vec{F}_N\|\right) \]

The `inf` norm takes the maximum component across the forces of all atoms in the system:

\[ \|\vec{F}\|_{inf} = \max\left(\|F_1^1\|, \|F_2^1\|, \|F_3^1\|, \cdots, \|F_1^N\|, \|F_2^N\|, \|F_3^N\|\right) \]

For the min styles `spin`, `spin/cg` and `spin/lbfgs`, the force norm is replaced by the spin-torque norm.

Keywords `alpha_damp` and `discrete_factor` only make sense when a `min_spin` command is declared. Keyword `alpha_damp` defines an analog of a magnetic Gilbert damping. It defines a relaxation rate toward an equilibrium for a given magnetic system. Keyword `discrete_factor` defines a discretization factor for the adaptive timestep used in the `spin` minimization. See `min_spin` for more information about those quantities.

The choice of a line search algorithm for the `spin/cg` and `spin/lbfgs` styles can be specified via the `line` keyword. The `spin_cubic` and `spin_none` keywords only make sense when one of those two minimization styles is declared. The `spin_cubic` performs the line search based on a cubic interpolation of the energy along the search direction. The
spin_none keyword deactivates the line search procedure. The spin_none is a default value for line keyword for both spin/lbfgs and spin/cg. Convergence of spin/lbfgs can be more robust if spin_cubic line search is used.

The Newton integrator used for fire minimization can be selected to be either the symplectic Euler (eulerimplicit) or velocity Verlet (verlet). tmax defines the maximum value for the adaptive timestep during a fire minimization. It is a multiplication factor applied to the current timestep (not in time unit). For example, tmax = 4.0 with a timestep of 2fs, means that the maximum value the timestep can reach during a fire minimization is 4fs. Note that parameter defaults has been chosen to be reliable in most cases, but one should consider adjusting timestep and tmax to optimize the minimization for large or complex systems. Other parameters of the fire minimization can be tuned (tmin, delaystep, dtgrow, dtshrink, alpha0, and alphashrink). Please refer to the references describing the min_style fire. An additional stopping criteria vdfmax is used by fire in order to avoid unnecessary looping when it is reasonable to think the system will not be relaxed further. Note that in this case the system will NOT have reached your minimization criteria. This could happen when the system comes to be stuck in a local basin of the phase space. vdfmax is the maximum number of consecutive iterations with P(t) < 0.

The min_style fire is an optimized implementation of min_style fire/old. It can however behave similarly to the fire/old style by using the following set of parameters:

```
min_modify integrator eulerexplicit tmax 10.0 tmin 0.0 delaystep 5 &
          dtgrow 1.1 dtshrink 0.5 alpha0 0.1 alphashrink 0.99 &
          vdfmax 100000 halfstepback no initialdelay no
```

16.71.4 Restrictions

For magnetic GNEB calculations, only spin_none value for line keyword can be used when minimization styles spin/cg and spin/lbfgs are employed. See neb/spin for more explanation.

16.71.5 Related commands

```
min_style, minimize
```

16.71.6 Default

The option defaults are dmax = 0.1, line = quadratic and norm = two.

For the spin, spin/cg and spin/lbfgs styles, the option defaults are alpha_damp = 1.0, discrete_factor = 10.0, line = spin_none, and norm = euclidean.

For the fire style, the option defaults are integrator = eulerimplicit, tmax = 10.0, tmin = 0.02, delaystep = 20, dtgrow = 1.1, dtshrink = 0.5, alpha0 = 0.25, alphashrink = 0.99, vdfmax = 2000, halfstepback = yes and initialdelay = yes.

```
min_style spin/lbfgs
min_modify line spin_cubic discrete_factor 10.0
```

16.74.3 Description

Apply a minimization algorithm to use when a `minimize` command is performed.

Style `spin` defines a damped spin dynamics with an adaptive timestep, according to:

\[
\frac{d\vec{s}_i}{dt} = \lambda \vec{s}_i \times (\vec{\omega}_i \times \vec{s}_i)
\]

with \(\lambda\) a damping coefficient (similar to a Gilbert damping). \(\lambda\) can be defined by setting the `alpha_damp` keyword with the `min_modify` command.

The minimization procedure solves this equation using an adaptive timestep. The value of this timestep is defined by the largest precession frequency that has to be solved in the system:

\[
\Delta t_{\text{max}} = \frac{2\pi}{\kappa |\vec{\omega}_{\text{max}}|}
\]

with \(|\vec{\omega}_{\text{max}}|\) the norm of the largest precession frequency in the system (across all processes, and across all replicas if a spin/neb calculation is performed).

\(\kappa\) defines a discretization factor `discrete_factor` for the definition of this timestep. `discrete_factor` can be defined with the `min_modify` command.

Style `spin/cg` defines an orthogonal spin optimization (OSO) combined to a conjugate gradient (CG) algorithm. The `min_modify` command can be used to couple the `spin/cg` to a line search procedure, and to modify the discretization factor `discrete_factor`. By default, style `spin/cg` does not employ the line search procedure and uses the adaptive timestep technique in the same way as style `spin`.

Style `spin/lbfgs` defines an orthogonal spin optimization (OSO) combined to a limited-memory Broyden-Fletcher-Goldfarb-Shanno (L-BFGS) algorithm. By default, style `spin/lbfgs` does not employ line search procedure. If the line search procedure is not used then the discrete factor defines the maximum root mean squared rotation angle of spins by equation \(\pi/5*Kappa\). The default value for Kappa is 10. The `spin_cubic` line search option can improve the convergence of the `spin/lbfgs` algorithm.
The `min_modify` command can be used to activate the line search procedure, and to modify the discretization factor `discrete_factor`.

For more information about styles `spin/cg` and `spin/lbfgs`, see their implementation reported in (Ivanov).

**Note:** All the `spin` styles replace the force tolerance by a torque tolerance. See `minimize` for more explanation.

**Note:** The `spin/cg` and `spin/lbfgs` styles can be used for magnetic NEB calculations only if the line search procedure is deactivated. See `neb/spin` for more explanation.

### 16.74.4 Restrictions

The `spin`, `spin/cg`, and `spin/lbfgs` styles are part of the SPIN package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

This minimization procedure is only applied to spin degrees of freedom for a frozen lattice configuration.

16.83.2 Examples

\begin{verbatim}
min_style cg
min_style fire
min_style spin
\end{verbatim}

16.83.3 Description

Choose a minimization algorithm to use when a \texttt{minimize} command is performed.

Style \texttt{cg} is the Polak-Ribiere version of the conjugate gradient (CG) algorithm. At each iteration the force gradient is combined with the previous iteration information to compute a new search direction perpendicular (conjugate) to the previous search direction. The PR variant affects how the direction is chosen and how the CG method is restarted when it ceases to make progress. The PR variant is thought to be the most effective CG choice for most problems.

Style \texttt{hftn} is a Hessian-free truncated Newton algorithm. At each iteration a quadratic model of the energy potential is solved by a conjugate gradient inner iteration. The Hessian (second derivatives) of the energy is not formed directly, but
approximated in each conjugate search direction by a finite difference directional derivative. When close to an energy minimum, the algorithm behaves like a Newton method and exhibits a quadratic convergence rate to high accuracy. In most cases the behavior of hftn is similar to cg, but it offers an alternative if cg seems to perform poorly. This style is not affected by the min_modify command.

Style sd is a steepest descent algorithm. At each iteration, the search direction is set to the downhill direction corresponding to the force vector (negative gradient of energy). Typically, steepest descent will not converge as quickly as CG, but may be more robust in some situations.

Style quickmin is a damped dynamics method described in (Sheppard), where the damping parameter is related to the projection of the velocity vector along the current force vector for each atom. The velocity of each atom is initialized to 0.0 by this style, at the beginning of a minimization.

Style fire is a damped dynamics method described in (Bitzek), which is similar to quickmin but adds a variable timestep and alters the projection operation to maintain components of the velocity non-parallel to the current force vector. The velocity of each atom is initialized to 0.0 by this style, at the beginning of a minimization. This style correspond to an optimized version described in (Guenole) that include different time integration schemes and defaults parameters. The default parameters can be modified with the command min_modify.

Style fire/old is the original implementation of fire in LAMMPS, conserved for backward compatibility. The main differences regarding the current version fire are: time integration by Explicit Euler only, different sequence in maintaining velocity components non-parallel to the current force vector and hard-coded minimization parameters. A complete description of the differences between fire/old and fire can be found in (Guenole) (where the current fire in LAMMPS is called fire2.0). By using an appropriate set of parameters, fire can behave similar to fire/old, as described in the min_modify command.

Style spin is a damped spin dynamics with an adaptive timestep.

Style spin/cg uses an orthogonal spin optimization (OSO) combined to a conjugate gradient (CG) approach to minimize spin configurations.

Style spin/lbfgs uses an orthogonal spin optimization (OSO) combined to a limited-memory Broyden-Fletcher-Goldfarb-Shanno (L-BFGS) approach to minimize spin configurations.

See the min/spin page for more information about the spin, spin/cg and spin/lbfgs styles.

Either the quickmin, fire and fire/old styles are useful in the context of nudged elastic band (NEB) calculations via the neb command.

Either the spin, spin/cg and spin/lbfgs styles are useful in the context of magnetic geodesic nudged elastic band (GNEB) calculations via the neb/spin command.

Note: The damped dynamic minimizers use whatever timestep you have defined via the timestep command. Often they will converge more quickly if you use a timestep about 10x larger than you would normally use for dynamics simulations. For fire, the default timestep is recommended to be equal to the one you would normally use for dynamics simulations.

Note: The quickmin, fire, fire/old, hftn, and cg/kk styles do not yet support the use of the fix box/relax command or minimizations involving the electron radius in eff models.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.
These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

16.83.4 Restrictions

The spin, spin/cg, and spin/lbfgps styles are part of the SPIN package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

minimize 0.0 1.0e-8 1000 100000
```

16.85.3 Description

Perform an energy minimization of the system, by iteratively adjusting atom coordinates. Iterations are terminated when one of the stopping criteria is satisfied. At that point the configuration will hopefully be in local potential energy minimum. More precisely, the configuration should approximate a critical point for the objective function (see below), which may or may not be a local minimum.

The minimization algorithm used is set by the `min_style` command. Other options are set by the `min_modify` command. Minimize commands can be interspersed with `run` commands to alternate between relaxation and dynamics. The minimizers bound the distance atoms move in one iteration, so that you can relax systems with highly overlapped atoms (large energies and forces) by pushing the atoms off of each other.

Alternate means of relaxing a system are to run dynamics with a small or _limited timestep_. Or dynamics can be run using `fix viscous` to impose a damping force that slowly drains all kinetic energy from the system. The _pair_style soft_ potential can be used to un-overlap atoms while running dynamics. Un-overlap atoms while running dynamics.

Note that you can minimize some atoms in the system while holding the coordinates of other atoms fixed by applying `fix setforce` to the other atoms. See a fuller discussion of using fixes while minimizing below.

The _minimization styles_ cg, sd, and hftn involves an outer iteration loop which sets the search direction along which atom coordinates are changed. An inner iteration is then performed using a line search algorithm. The line search typically evaluates forces and energies several times to set new coordinates. Currently, a backtracking algorithm is used which may not be optimal in terms of the number of force evaluations performed, but appears to be more robust than previous line searches we have tried. The backtracking method is described in Nocedal and Wright’s Numerical Optimization (Procedure 3.1 on p 41).

The _minimization styles_ quickmin, fire and fire/old perform damped dynamics using an Euler integration step. Thus they require a _timestep_ be defined.

**Note:** The damped dynamic minimizers use whatever timestep you have defined via the _timestep_ command. Often they will converge more quickly if you use a timestep about 10x larger than you would normally use for dynamics simulations.

In all cases, the objective function being minimized is the total potential energy of the system as a function of the N atom coordinates:

\[
E(r_1, r_2, \ldots, r_N) = \sum_{i,j} E_{\text{pair}}(r_i, r_j) + \sum_{ij} E_{\text{bond}}(r_i, r_j) + \sum_{ijk} E_{\text{angle}}(r_i, r_j, r_k) + \sum_{ijkl} E_{\text{dihedral}}(r_i, r_j, r_k, r_l) + \sum_{ijkl} E_{\text{improper}}(r_i, r_j, r_k, r_l) + \sum_{i} E_{\text{fix}}(r_i)
\]

where the first term is the sum of all non-bonded _pairwise interactions_ including _long-range Coulombic interactions_, the second through fifth terms are _bond, angle, dihedral, and improper_ interactions respectively, and the last term is energy due to _fixes_ which can act as constraints or apply force to atoms, such as through interaction with a wall. See the discussion below about how fix commands affect minimization.

The starting point for the minimization is the current configuration of the atoms.
The minimization procedure stops if any of several criteria are met:

- the change in energy between outer iterations is less than $etol$
- the 2-norm (length) of the global force vector is less than the $ftol$
- the line search fails because the step distance backtracks to 0.0
- the number of outer iterations or timesteps exceeds $maxiter$
- the number of total force evaluations exceeds $maxeval$

**Note:** the minimization style spin, spin/cg, and spin/lbfgs replace the force tolerance $ftol$ by a torque tolerance. The minimization procedure stops if the 2-norm (length) of the torque vector on atom (defined as the cross product between the atomic spin and its precession vectors omega) is less than $ftol$, or if any of the other criteria are met. Torque have the same units as the energy.

**Note:** You can also use the fix halt command to specify a general criterion for exiting a minimization, that is a calculation performed on the state of the current system, as defined by an equal-style variable.

For the first criterion, the specified energy tolerance $etol$ is unitless; it is met when the energy change between successive iterations divided by the energy magnitude is less than or equal to the tolerance. For example, a setting of 1.0e-4 for $etol$ means an energy tolerance of one part in 10^4. For the damped dynamics minimizers this check is not performed for a few steps after velocities are reset to 0, otherwise the minimizer would prematurely converge.

For the second criterion, the specified force tolerance $ftol$ is in force units, since it is the length of the global force vector for all atoms, e.g. a vector of size 3N for N atoms. Since many of the components will be near zero after minimization, you can think of $ftol$ as an upper bound on the final force on any component of any atom. For example, a setting of 1.0e-4 for $ftol$ means no x, y, or z component of force on any atom will be larger than 1.0e-4 (in force units) after minimization.

Either or both of the $etol$ and $ftol$ values can be set to 0.0, in which case some other criterion will terminate the minimization.

During a minimization, the outer iteration count is treated as a timestep. Output is triggered by this timestep, e.g. thermodynamic output or dump and restart files.

Using the thermo_style custom command with the $fmax$ or $fnorm$ keywords can be useful for monitoring the progress of the minimization. Note that these outputs will be calculated only from forces on the atoms, and will not include any extra degrees of freedom, such as from the fix box/relax command.

Following minimization, a statistical summary is printed that lists which convergence criterion caused the minimizer to stop, as well as information about the energy, force, final line search, and iteration counts. An example is as follows:

```
Minimization stats:
  Stopping criterion = max iterations
  Energy initial, next-to-last, final =
    -0.626828169302 -2.82642039062 -2.82643549739
  Force two-norm initial, final = 2052.1 91.9642
  Force max component initial, final = 346.048 9.78056
  Final line search alpha, max atom move = 2.23899e-06 2.18986e-05
  Iterations, force evaluations = 2000 12724
```

The 3 energy values are for before and after the minimization and on the next-to-last iteration. This is what the $etol$ parameter checks.
The two-norm force values are the length of the global force vector before and after minimization. This is what the $ftol$ parameter checks.

The max-component force values are the absolute value of the largest component ($x,y,z$) in the global force vector, i.e. the infinity-norm of the force vector.

The alpha parameter for the line-search, when multiplied by the max force component (on the last iteration), gives the max distance any atom moved during the last iteration. Alpha will be 0.0 if the line search could not reduce the energy. Even if alpha is non-zero, if the “max atom move” distance is tiny compared to typical atom coordinates, then it is possible the last iteration effectively caused no atom movement and thus the evaluated energy did not change and the minimizer terminated. Said another way, even with non-zero forces, it’s possible the effect of those forces is to move atoms a distance less than machine precision, so that the energy cannot be further reduced.

The iterations and force evaluation values are what is checked by the $maxiter$ and $maxeval$ parameters.

---

**Note:** There are several force fields in LAMMPS which have discontinuities or other approximations which may prevent you from performing an energy minimization to high tolerances. For example, you should use a pair style that goes to 0.0 at the cutoff distance when performing minimization (even if you later change it when running dynamics). If you do not do this, the total energy of the system will have discontinuities when the relative distance between any pair of atoms changes from cutoff+epsilon to cutoff-epsilon and the minimizer may behave poorly. Some of the many-body potentials use splines and other internal cutoffs that inherently have this problem. The long-range Coulombic styles (PPPM, Ewald) are approximate to within the user-specified tolerance, which means their energy and forces may not agree to a higher precision than the Kspace-specified tolerance. In all these cases, the minimizer may give up and stop before finding a minimum to the specified energy or force tolerance.

Note that a cutoff Lennard-Jones potential (and others) can be shifted so that its energy is 0.0 at the cutoff via the pair_modify command. See the doc pages for individual pair styles for details. Note that Coulombic potentials always have a cutoff, unless versions with a long-range component are used (e.g. pair_style lj/cut/coul/long). The CHARMM potentials go to 0.0 at the cutoff (e.g. pair_style lj/charmm/coul/charmm), as do the GROMACS potentials (e.g. pair_style lj/gromacs).

If a soft potential (pair_style soft) is used the Astop value is used for the prefactor (no time dependence).

The fix box/relax command can be used to apply an external pressure to the simulation box and allow it to shrink/expand during the minimization.

Only a few other fixes (typically those that add forces) are invoked during minimization. See the doc pages for individual fix commands to see which ones are relevant. Current examples of fixes that can be used include:

- fix addforce
- fix addtorque
- fix efield
- fix enforce2d
- fix indent
- fix lineforce
- fix planeforce
- fix setforce
- fix spring
- fix spring/self
- fix viscous
• fix wall
• fix wall/region

**Note:** Some fixes which are invoked during minimization have an associated potential energy. For that energy to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the `fix_modify energy` option for that fix. The doc pages for individual `fix` commands specify if this should be done.

**Note:** The minimizers in LAMMPS do not allow for bonds (or angles, etc) to be held fixed while atom coordinates are being relaxed, e.g. via `fix shake` or `fix rigid`. See more info in the Restrictions section below.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 16.85.4 Restrictions

Features that are not yet implemented are listed here, in case someone knows how they could be coded:

It is an error to use `fix shake` with minimization because it turns off bonds that should be included in the potential energy of the system. The effect of a fix shake can be approximated during a minimization by using stiff spring constants for the bonds and/or angles that would normally be constrained by the SHAKE algorithm.

`Fix rigid` is also not supported by minimization. It is not an error to have it defined, but the energy minimization will not keep the defined body(s) rigid during the minimization. Note that if bonds, angles, etc internal to a rigid body have been turned off (e.g. via `neigh_modify exclude`), they will not contribute to the potential energy which is probably not what is desired.

Pair potentials that produce torque on a particle (e.g. granular potentials or the GayBerne potential for ellipsoidal particles) are not relaxed by a minimization. More specifically, radial relaxations are induced, but no rotations are induced by a minimization, so such a system will not fully relax.

16.86.3 Description

Define a molecule template that can be used as part of other LAMMPS commands, typically to define a collection of particles as a bonded molecule or a rigid body. Commands that currently use molecule templates include:

- fix deposit
- fix pour
- fix rigid/small
- fix shake
- fix gcmc
- fix bond/react
- create_atoms
- atom_style template

The ID of a molecule template can only contain alphanumeric characters and underscores.

A single template can contain multiple molecules, listed one per file. Some of the commands listed above currently use only the first molecule in the template, and will issue a warning if the template contains multiple molecules. The atom_style template command allows multiple-molecule templates to define a system with more than one templated molecule.

Each filename can be followed by optional keywords which are applied only to the molecule in the file as used in this template. This is to make it easy to use the same molecule file in different molecule templates or in different simulations. You can specify the same file multiple times with different optional keywords.

The offset, toff, boff, aoff, doff, ioff keywords add the specified offset values to the atom types, bond types, angle types, dihedral types, and/or improper types as they are read from the molecule file. E.g. if toff = 2, and the file uses atom types 1,2,3, then each created molecule will have atom types 3,4,5. For the offset keyword, all five offset values must be specified, but individual values will be ignored if the molecule template does not use that attribute (e.g. no bonds).

The scale keyword scales the size of the molecule. This can be useful for modeling polydisperse granular rigid bodies. The scale factor is applied to each of these properties in the molecule file, if they are defined: the individual particle coordinates (Coords section), the individual mass of each particle (Masses section), the individual diameters of each particle (Diameters section), the total mass of the molecule (header keyword = mass), the center-of-mass of the molecule (header keyword = com), and the moments of inertia of the molecule (header keyword = inertia).

Note: The molecule command can be used to define molecules with bonds, angles, dihedrals, impropers, or special bond lists of neighbors within a molecular topology, so that you can later add the molecules to your simulation, via one or more of the commands listed above. Since this topology-related information requires that suitable storage is reserved when LAMMPS creates the simulation box (e.g. when using the create_box command or the read_data command) suitable space has to be reserved so you do not overflow those pre-allocated data structures when adding molecules later. Both the create_box command and the read_data command have “extra” options which insure space is allocated for storing topology info for molecules that are added later.

The format of an individual molecule file is similar but (not identical) to the data file read by the read_data commands, and is as follows.

A molecule file has a header and a body. The header appears first. The first line of the header is always skipped; it typically contains a description of the file. Then lines are read one at a time. Lines can have a trailing comment starting with ‘#’ that is ignored. If the line is blank (only white-space after comment is deleted), it is skipped. If the line contains a header keyword, the corresponding value(s) is read from the line. If it does not contain a header keyword, the line begins the body of the file.
The body of the file contains zero or more sections. The first line of a section has only a keyword. The next line is skipped. The remaining lines of the section contain values. The number of lines depends on the section keyword as described below. Zero or more blank lines can be used between sections. Sections can appear in any order, with a few exceptions as noted below.

These are the recognized header keywords. Header lines can come in any order. The numeric value(s) are read from the beginning of the line. The keyword should appear at the end of the line. All these settings have default values, as explained below. A line need only appear if the value(s) are different than the default.

- **N atoms** = # of atoms N in molecule, default = 0
- **Nb bonds** = # of bonds Nb in molecule, default = 0
- **Na angles** = # of angles Na in molecule, default = 0
- **Nd dihedrals** = # of dihedrals Nd in molecule, default = 0
- **Ni impropers** = # of impropers Ni in molecule, default = 0
- **Nf fragments** = # of fragments in molecule, default = 0
- **Mtotal mass** = total mass of molecule
- **Xc Yc Zc com** = coordinates of center-of-mass of molecule
- **Ixx Iyy Izz Ixy Ixz Iyz inertia** = 6 components of inertia tensor of molecule

For **mass**, **com**, and **inertia**, the default is for LAMMPS to calculate this quantity itself if needed, assuming the molecules consists of a set of point particles or finite-size particles (with a non-zero diameter) that do not overlap. If finite-size particles in the molecule do overlap, LAMMPS will not account for the overlap effects when calculating any of these 3 quantities, so you should pre-compute them yourself and list the values in the file.

The mass and center-of-mass coordinates (Xc,Yc,Zc) are self-explanatory. The 6 moments of inertia (Ixx,Iyy,Izz,Ixy,Ixz,Iyz) should be the values consistent with the current orientation of the rigid body around its center of mass. The values are with respect to the simulation box XYZ axes, not with respect to the principal axes of the rigid body itself. LAMMPS performs the latter calculation internally.

These are the allowed section keywords for the body of the file.

- **Coords, Types, Molecules, Fragments, Charges, Diameters, Masses** = atom-property sections
- **Bonds, Angles, Dihedrals, Improper** = molecular topology sections
- **Special Bond Counts, Special Bonds** = special neighbor info
- **Shake Flags, Shake Atoms, Shake Bond Types** = SHAKE info

If a Bonds section is specified then the Special Bond Counts and Special Bonds sections can also be used, if desired, to explicitly list the 1-2, 1-3, 1-4 neighbors within the molecule topology (see details below). This is optional since if these sections are not included, LAMMPS will auto-generate this information. Note that LAMMPS uses this info to properly exclude or weight bonded pairwise interactions between bonded atoms. See the **special_bonds** command for more details. One reason to list the special bond info explicitly is for the thermalized Drude oscillator model which treats the bonds between nuclear cores and Drude electrons in a different manner.

**Note:** Whether a section is required depends on how the molecule template is used by other LAMMPS commands. For example, to add a molecule via the **fix deposit** command, the Coords and Types sections are required. To add a rigid body via the **fix pour** command, the Bonds (Angles, etc) sections are not required, since the molecule will be treated as a rigid body. Some sections are optional. For example, the **fix pour** command can be used to add “molecules” which are clusters of finite-size granular particles. If the Diameters section is not specified, each particle in the molecule will have a default diameter of 1.0. See the doc pages for LAMMPS commands that use molecule templates for more details.
Each section is listed below in alphabetic order. The format of each section is described including the number of lines it must contain and rules (if any) for whether it can appear in the data file. For per-atom sections, entries should be numbered from 1 to Natoms (where Natoms is the number of atoms in the template), indicating which atom (or bond, etc) the entry applies to. Per-atom sections need to include a setting for every atom, but the atoms can be listed in any order.

**Coords section:**
- one line per atom
- line syntax: ID x y z
- x,y,z = coordinate of atom

**Types section:**
- one line per atom
- line syntax: ID type
- type = atom type of atom

**Molecules section:**
- one line per atom
- line syntax: ID molecule-ID
- molecule-ID = molecule ID of atom

**Fragments section:**
- one line per fragment
- line syntax: ID a b c d ...
- a,b,c,d,... = IDs of atoms in fragment
The ID of a fragment can only contain alphanumeric characters and underscores. The atom IDs should be values from 1 to Natoms, where Natoms = # of atoms in the molecule.

**Charges section:**
- one line per atom
- line syntax: ID q
- q = charge on atom
This section is only allowed for *atom styles* that support charge. If this section is not included, the default charge on each atom in the molecule is 0.0.

**Diameters section:**
- one line per atom
- line syntax: ID diam
• diam = diameter of atom

This section is only allowed for atom styles that support finite-size spherical particles, e.g. atom_style sphere. If not listed, the default diameter of each atom in the molecule is 1.0.

**Masses** section:

- one line per atom
- line syntax: ID mass
- mass = mass of atom

This section is only allowed for atom styles that support per-atom mass, as opposed to per-type mass. See the mass command for details. If this section is not included, the default mass for each atom is derived from its volume (see Diameters section) and a default density of 1.0, in units of mass/volume.

**Bonds** section:

- one line per bond
- line syntax: ID type atom1 atom2
- type = bond type (1-Nbondtype)
- atom1,atom2 = IDs of atoms in bond

The IDs for the two atoms in each bond should be values from 1 to Natoms, where Natoms = # of atoms in the molecule.

**Angles** section:

- one line per angle
- line syntax: ID type atom1 atom2 atom3
- type = angle type (1-Nangletype)
- atom1,atom2,atom3 = IDs of atoms in angle

The IDs for the three atoms in each angle should be values from 1 to Natoms, where Natoms = # of atoms in the molecule. The 3 atoms are ordered linearly within the angle. Thus the central atom (around which the angle is computed) is the atom2 in the list.

**Dihedrals** section:

- one line per dihedral
- line syntax: ID type atom1 atom2 atom3 atom4
- type = dihedral type (1-Ndihedraltype)
- atom1,atom2,atom3,atom4 = IDs of atoms in dihedral

The IDs for the four atoms in each dihedral should be values from 1 to Natoms, where Natoms = # of atoms in the molecule. The 4 atoms are ordered linearly within the dihedral.

**Impropers** section:

- one line per improper
• line syntax: ID type atom1 atom2 atom3 atom4
  • type = improper type (1-Nimpropertype)
  • atom1, atom2, atom3, atom4 = IDs of atoms in improper

The IDs for the four atoms in each improper should be values from 1 to Natoms, where Natoms = # of atoms in the molecule. The ordering of the 4 atoms determines the definition of the improper angle used in the formula for the defined improper style. See the doc pages for individual styles for details.

Special Bond Counts section:
• one line per atom
• line syntax: ID N1 N2 N3
  • N1 = # of 1-2 bonds
  • N2 = # of 1-3 bonds
  • N3 = # of 1-4 bonds

N1, N2, N3 are the number of 1-2, 1-3, 1-4 neighbors respectively of this atom within the topology of the molecule. See the special_bonds page for more discussion of 1-2, 1-3, 1-4 neighbors. If this section appears, the Special Bonds section must also appear.

As explained above, LAMMPS will auto-generate this information if this section is not specified. If specified, this section will override what would be auto-generated.

Special Bonds section:
• one line per atom
• line syntax: ID a b c d ...
  • a, b, c, d,... = IDs of atoms in N1+N2+N3 special bonds

A, b, c, d, etc are the IDs of the n1+n2+n3 atoms that are 1-2, 1-3, 1-4 neighbors of this atom. The IDs should be values from 1 to Natoms, where Natoms = # of atoms in the molecule. The first N1 values should be the 1-2 neighbors, the next N2 should be the 1-3 neighbors, the last N3 should be the 1-4 neighbors. No atom ID should appear more than once. See the special_bonds doc page for more discussion of 1-2, 1-3, 1-4 neighbors. If this section appears, the Special Bond Counts section must also appear.

As explained above, LAMMPS will auto-generate this information if this section is not specified. If specified, this section will override what would be auto-generated.

Shake Flags section:
• one line per atom
• line syntax: ID flag
  • flag = 0,1,2,3,4

This section is only needed when molecules created using the template will be constrained by SHAKE via the “fix shake” command. The other two Shake sections must also appear in the file, following this one.

The meaning of the flag for each atom is as follows. See the fix shake page for a further description of SHAKE clusters.
  • 0 = not part of a SHAKE cluster
  • 1 = part of a SHAKE angle cluster (two bonds and the angle they form)
• 2 = part of a 2-atom SHAKE cluster with a single bond
• 3 = part of a 3-atom SHAKE cluster with two bonds
• 4 = part of a 4-atom SHAKE cluster with three bonds

Shake Atoms section:
• one line per atom
• line syntax: ID a b c d
• a,b,c,d = IDs of atoms in cluster

This section is only needed when molecules created using the template will be constrained by SHAKE via the “fix shake” command. The other two Shake sections must also appear in the file.

The a,b,c,d values are atom IDs (from 1 to Natoms) for all the atoms in the SHAKE cluster that this atom belongs to. The number of values that must appear is determined by the shake flag for the atom (see the Shake Flags section above). All atoms in a particular cluster should list their a,b,c,d values identically.

If flag = 0, no a,b,c,d values are listed on the line, just the (ignored) ID.
If flag = 1, a,b,c are listed, where a = ID of central atom in the angle, and b,c the other two atoms in the angle.
If flag = 2, a,b are listed, where a = ID of atom in bond with the lowest ID, and b = ID of atom in bond with the highest ID.
If flag = 3, a,b,c are listed, where a = ID of central atom, and b,c = IDs of other two atoms bonded to the central atom.
If flag = 4, a,b,c,d are listed, where a = ID of central atom, and b,c,d = IDs of other three atoms bonded to the central atom.

See the fix shake page for a further description of SHAKE clusters.

Shake Bond Types section:
• one line per atom
• line syntax: ID a b c
• a,b,c = bond types (or angle type) of bonds (or angle) in cluster

This section is only needed when molecules created using the template will be constrained by SHAKE via the “fix shake” command. The other two Shake sections must also appear in the file.

The a,b,c values are bond types (from 1 to Nbondtypes) for all bonds in the SHAKE cluster that this atom belongs to. The number of values that must appear is determined by the shake flag for the atom (see the Shake Flags section above). All atoms in a particular cluster should list their a,b,c values identically.

If flag = 0, no a,b,c values are listed on the line, just the (ignored) ID.
If flag = 1, a,b,c are listed, where a = bondtype of the bond between the central atom and the first non-central atom (value b in the Shake Atoms section), b = bondtype of the bond between the central atom and the second non-central atom (value c in the Shake Atoms section), and c = the angle type (1 to Nangletypes) of the angle between the 3 atoms.
If flag = 2, only a is listed, where a = bondtype of the bond between the 2 atoms in the cluster.
If flag = 3, a,b are listed, where a = bondtype of the bond between the central atom and the first non-central atom (value b in the Shake Atoms section), and b = bondtype of the bond between the central atom and the second non-central atom (value c in the Shake Atoms section).
If flag = 4, a,b,c are listed, where a = bondtype of the bond between the central atom and the first non-central atom (value b in the Shake Atoms section), b = bondtype of the bond between the central atom and the second non-central atom (value c in the Shake Atoms section), and c = bondtype of the bond between the central atom and the third non-central atom (value d in the Shake Atoms section).

See the fix shake page for a further description of SHAKE clusters.

16.87.3 Description

Perform a nudged elastic band (NEB) calculation using multiple replicas of a system. Two or more replicas must be used; the first and last are the end points of the transition path.

NEB is a method for finding both the atomic configurations and height of the energy barrier associated with a transition state, e.g. for an atom to perform a diffusive hop from one energy basin to another in a coordinated fashion with its neighbors. The implementation in LAMMPS follows the discussion in these 4 papers: (HenkelmanA), (HenkelmanB), (Nakano) and (Maras).

Each replica runs on a partition of one or more processors. Processor partitions are defined at run-time using the `-partition command-line switch`. Note that if you have MPI installed, you can run a multi-replica simulation with more replicas (partitions) than you have physical processors, e.g you can run a 10-replica simulation on just one or two processors. You will simply not get the performance speed-up you would see with one or more physical processors per replica. See the `Howto replica` doc page for further discussion.

**Note:** As explained below, a NEB calculation performs a damped dynamics minimization across all the replicas. The minimizer uses whatever timestep you have defined in your input script, via the `timestep` command. Often NEB will converge more quickly if you use a timestep about 10x larger than you would normally use for dynamics simulations.

When a NEB calculation is performed, it is assumed that each replica is running the same system, though LAMMPS does not check for this. I.e. the simulation domain, the number of atoms, the interaction potentials, and the starting configuration when the `neb` command is issued should be the same for every replica.

In a NEB calculation each replica is connected to other replicas by inter-replica nudging forces. These forces are imposed by the `fix neb` command, which must be used in conjunction with the `neb` command. The group used to define the `fix neb` command defines the NEB atoms which are the only ones that inter-replica springs are applied to. If the group does not include all atoms, then non-NEB atoms have no inter-replica springs and the forces they feel and their motion is computed in the usual way due only to other atoms within their replica. Conceptually, the non-NEB atoms provide a background force field for the NEB atoms. They can be allowed to move during the NEB minimization procedure (which will typically induce different coordinates for non-NEB atoms in different replicas), or held fixed using other LAMMPS commands such as `fix setforce`. Note that the `partition` command can be used to invoke a command on a subset of the replicas, e.g. if you wish to hold NEB or non-NEB atoms fixed in only the end-point replicas.

The initial atomic configuration for each of the replicas can be specified in different manners via the `file-style` setting, as discussed below. Only atoms whose initial coordinates should differ from the current configuration need be specified.

Conceptually, the initial and final configurations for the first replica should be states on either side of an energy barrier.

As explained below, the initial configurations of intermediate replicas can be atomic coordinates interpolated in a linear fashion between the first and last replicas. This is often adequate for simple transitions. For more complex transitions, it may lead to slow convergence or even bad results if the minimum energy path (MEP, see below) of states over the barrier cannot be correctly converged to from such an initial path. In this case, you will want to generate initial states for the intermediate replicas that are geometrically closer to the MEP and read them in.

For a `file-style` setting of `final`, a filename is specified which contains atomic coordinates for zero or more atoms, in the format described below. For each atom that appears in the file, the new coordinates are assigned to that atom in
LAMMPS Documentation, Release patch 23Jun2022

the final replica. Each intermediate replica also assigns a new position to that atom in an interpolated manner. This is done by using the current position of the atom as the starting point and the read-in position as the final point. The distance between them is calculated, and the new position is assigned to be a fraction of the distance. E.g. if there are 10 replicas, the second replica will assign a position that is 10% of the distance along a line between the starting and final point, and the 9th replica will assign a position that is 90% of the distance along the line. Note that for this procedure to produce consistent coordinates across all the replicas, the current coordinates need to be the same in all replicas. LAMMPS does not check for this, but invalid initial configurations will likely result if it is not the case.

**Note:** The “distance” between the starting and final point is calculated in a minimum-image sense for a periodic simulation box. This means that if the two positions are on opposite sides of a box (periodic in that dimension), the distance between them will be small, because the periodic image of one of the atoms is close to the other. Similarly, even if the assigned position resulting from the interpolation is outside the periodic box, the atom will be wrapped back into the box when the NEB calculation begins.

For a **file-style** setting of *each*, a filename is specified which is assumed to be unique to each replica. This can be done by using a variable in the filename, e.g.

```plaintext
variable i equal part neb 0.0 0.001 1000 500 50 each coords.initial.$i
```

which in this case will substitute the partition ID (0 to N-1) for the variable I, which is also effectively the replica ID. See the variable command for other options, such as using world-, universe-, or uloop-style variables.

Each replica (except the first replica) will read its file, formatted as described below, and for any atom that appears in the file, assign the specified coordinates to its atom. The various files do not need to contain the same set of atoms.

For a **file-style** setting of *none*, no filename is specified. Each replica is assumed to already be in its initial configuration at the time the neb command is issued. This allows each replica to define its own configuration by reading a replica-specific data or restart or dump file, via the read_data, read_restart, or read_dump commands. The replica-specific names of these files can be specified as in the discussion above for the *each* file-style. Also see the section below for how a NEB calculation can produce restart files, so that a long calculation can be restarted if needed.

**Note:** None of the file-style settings change the initial configuration of any atom in the first replica. The first replica must thus be in the correct initial configuration at the time the neb command is issued.

A NEB calculation proceeds in two stages, each of which is a minimization procedure, performed via damped dynamics. To enable this, you must first define a damped dynamics **min_style**, such as quickmin or fire. The cg, sd, and hftn styles cannot be used, since they perform iterative line searches in their inner loop, which cannot be easily synchronized across multiple replicas.

The minimizer tolerances for energy and force are set by etol and ftol, the same as for the minimize command.

A non-zero etol means that the NEB calculation will terminate if the energy criterion is met by every replica. The energies being compared to etol do not include any contribution from the inter-replica nudging forces, since these are non-conservative. A non-zero ftol means that the NEB calculation will terminate if the force criterion is met by every replica. The forces being compared to ftol include the inter-replica nudging forces.

The maximum number of iterations in each stage is set by N1 and N2. These are effectively timestep counts since each iteration of damped dynamics is like a single timestep in a dynamics run. During both stages, the potential energy of each replica and its normalized distance along the reaction path (reaction coordinate RD) will be printed to the screen and log file every Nevery timesteps. The RD is 0 and 1 for the first and last replica. For intermediate replicas, it is the cumulative distance (normalized by the total cumulative distance) between adjacent replicas, where “distance” is defined as the length of the 3N-vector of differences in atomic coordinates, where N is the number of NEB atoms.
involved in the transition. These outputs allow you to monitor NEB’s progress in finding a good energy barrier. \( N1 \) and \( N2 \) must both be multiples of \( N_{\text{every}} \).

In the first stage of NEB, the set of replicas should converge toward a minimum energy path (MEP) of conformational states that transition over a barrier. The MEP for a transition is defined as a sequence of \( 3N \)-dimensional states, each of which has a potential energy gradient parallel to the MEP itself. The configuration of highest energy along a MEP corresponds to a saddle point. The replica states will also be roughly equally spaced along the MEP due to the inter-replica nudging force added by the \texttt{fix neb} command.

In the second stage of NEB, the replica with the highest energy is selected and the inter-replica forces on it are converted to a force that drives its atom coordinates to the top or saddle point of the barrier, via the barrier-climbing calculation described in (HenkelmanB). As before, the other replicas rearrange themselves along the MEP so as to be roughly equally spaced.

When both stages are complete, if the NEB calculation was successful, the configurations of the replicas should be along (close to) the MEP and the replica with the highest energy should be an atomic configuration at (close to) the saddle point of the transition. The potential energies for the set of replicas represents the energy profile of the transition along the MEP.

A few other settings in your input script are required or advised to perform a NEB calculation. See the NOTE about the choice of timestep at the beginning of this doc page.

An atom map must be defined which it is not by default for \texttt{atom_style atomic} problems. The \texttt{atom_modify map} command can be used to do this.

The minimizers in LAMMPS operate on all atoms in your system, even non-NEB atoms, as defined above. To prevent non-NEB atoms from moving during the minimization, you should use the \texttt{fix setforce} command to set the force on each of those atoms to 0.0. This is not required, and may not even be desired in some cases, but if those atoms move too far (e.g. because the initial state of your system was not well-minimized), it can cause problems for the NEB procedure.

The damped dynamics \texttt{minimizers}, such as \texttt{quickmin} and \texttt{fire}, adjust the position and velocity of the atoms via an Euler integration step. Thus you must define an appropriate \texttt{timestep} to use with NEB. As mentioned above, NEB will often converge more quickly if you use a timestep about 10x larger than you would normally use for dynamics simulations.

Each file read by the \texttt{neb} command containing atomic coordinates used to initialize one or more replicas must be formatted as follows.

The file can be ASCII text or a gzipped text file (detected by a .gz suffix). The file can contain initial blank lines or comment lines starting with “#” which are ignored. The first non-blank, non-comment line should list \( N \) = the number of lines to follow. The \( N \) successive lines contain the following information:

\[
\begin{array}{ccc}
\text{ID1} & x1 & y1 & z1 \\
\text{ID2} & x2 & y2 & z2 \\
\vdots \\
\text{ID}N & xN & yN & zN \\
\end{array}
\]

The fields are the atom ID, followed by the x,y,z coordinates. The lines can be listed in any order. Additional trailing information on the line is \texttt{OK}, such as a comment.

Note that for a typical NEB calculation you do not need to specify initial coordinates for very many atoms to produce differing starting and final replicas whose intermediate replicas will converge to the energy barrier. Typically only new coordinates for atoms geometrically near the barrier need be specified.

Also note there is no requirement that the atoms in the file correspond to the NEB atoms in the group defined by the \texttt{fix neb} command. Not every NEB atom need be in the file, and non-NEB atoms can be listed in the file.
Four kinds of output can be generated during a NEB calculation: energy barrier statistics, thermodynamic output by each replica, dump files, and restart files.

When running with multiple partitions (each of which is a replica in this case), the print-out to the screen and master log.lammps file contains a line of output, printed once every $Nevery$ timesteps. It contains the timestep, the maximum force per replica, the maximum force per atom (in any replica), potential gradients in the initial, final, and climbing replicas, the forward and backward energy barriers, the total reaction coordinate (RDT), and the normalized reaction coordinate and potential energy of each replica.

The “maximum force per replica” is the two-norm of the 3N-length force vector for the atoms in each replica, maximized across replicas, which is what the $ftol$ setting is checking against. In this case, N is all the atoms in each replica. The “maximum force per atom” is the maximum force component of any atom in any replica. The potential gradients are the two-norm of the 3N-length force vector solely due to the interaction potential i.e. without adding in inter-replica forces.

The “reaction coordinate” (RD) for each replica is the two-norm of the 3N-length vector of distances between its atoms and the preceding replica’s atoms, added to the RD of the preceding replica. The RD of the first replica RD1 = 0.0; the RD of the final replica RDN = RDT, the total reaction coordinate. The normalized RDs are divided by RDT, so that they form a monotonically increasing sequence from zero to one. When computing RD, N only includes the atoms being operated on by the fix neb command.

The forward (reverse) energy barrier is the potential energy of the highest replica minus the energy of the first (last) replica.

Supplementary information for all replicas can be printed out to the screen and master log.lammps file by adding the verbose keyword. This information include the following. The “path angle” (pathangle) for the replica i which is the angle between the 3N-length vectors (Ri-1 - Ri) and (Ri+1 - Ri) (where Ri is the atomic coordinates of replica i). A “path angle” of 180 degrees indicates that replicas i-1, i and i+1 are aligned. “anglegrad” is the angle between the 3N-length tangent vector and the 3N-length force vector at image i. The tangent vector is calculated as in (Henkelman2000) for all intermediate replicas and at R2 - R1 and RM - RM-1 for the first and last replica, respectively. “anglegrad” is the angle between the 3N-length energy gradient vector of replica i and that of replica i+1. It is not defined for the final replica and reads nan. gradV is the norm of the energy gradient of image i. ReplicaForce is the two-norm of the 3N-length force vector (including nudging forces) for replica i. MaxAtomForce is the maximum force component of any atom in replica i.

When a NEB calculation does not converge properly, the supplementary information can help understanding what is going wrong. For instance when the path angle becomes acute, the definition of tangent used in the NEB calculation is questionable and the NEB cannot may diverge (Maras).

When running on multiple partitions, LAMMPS produces additional log files for each partition, e.g. log.lammps.0, log.lammps.1, etc. For a NEB calculation, these contain the thermodynamic output for each replica.

If dump commands in the input script define a filename that includes a universe or uloop style variable, then one dump file (per dump command) will be created for each replica. At the end of the NEB calculation, the final snapshot in each file will contain the sequence of snapshots that transition the system over the energy barrier. Earlier snapshots will show the convergence of the replicas to the MEP.

Likewise, restart filenames can be specified with a universe or uloop style variable, to generate restart files for each replica. These may be useful if the NEB calculation fails to converge properly to the MEP, and you wish to restart the calculation from an intermediate point with altered parameters.

There are 2 Python scripts provided in the tools/python directory, neb_combine.py and neb_final.py, which are useful in analyzing output from a NEB calculation. Assume a NEB simulation with M replicas, and the NEB atoms labeled with a specific atom type.

The neb_combine.py script extracts atom coords for the NEB atoms from all M dump files and creates a single dump file where each snapshot contains the NEB atoms from all the replicas and one copy of non-NEB atoms from the first replica (presumed to be identical in other replicas). This can be visualized/animated to see how the NEB atoms relax as the NEB calculation proceeds.
The neb_final.py script extracts the final snapshot from each of the M dump files to create a single dump file with M snapshots. This can be visualized to watch the system make its transition over the energy barrier.

To illustrate, here are images from the final snapshot produced by the neb_combine.py script run on the dump files produced by the two example input scripts in examples/neb.

neb/spin 0.0 0.001 1000 500 50 none verbose

16.88.3 Description

Perform a geodesic nudged elastic band (GNEB) calculation using multiple replicas of a system. Two or more replicas must be used; the first and last are the end points of the transition path.

GNEB is a method for finding both the spin configurations and height of the energy barrier associated with a transition state, e.g. spins to perform a collective rotation from one energy basin to another. The implementation in LAMMPS follows the discussion in the following paper: (BessarabA).

Each replica runs on a partition of one or more processors. Processor partitions are defined at run-time using the -partition command-line switch. Note that if you have MPI installed, you can run a multi-replica simulation with more replicas (partitions) than you have physical processors, e.g. you can run a 10-replica simulation on just one or two processors. You will simply not get the performance speed-up you would see with one or more physical processors per replica. See the Howto replica doc page for further discussion.
Note: As explained below, a GNEB calculation performs a minimization across all the replicas. One of the spin style minimizers has to be defined in your input script.

When a GNEB calculation is performed, it is assumed that each replica is running the same system, though LAMMPS does not check for this. I.e. the simulation domain, the number of magnetic atoms, the interaction potentials, and the starting configuration when the neb command is issued should be the same for every replica.

In a GNEB calculation each replica is connected to other replicas by inter-replica nudging forces. These forces are imposed by the fix neb/spin command, which must be used in conjunction with the neb command. The group used to define the fix neb/spin command defines the GNEB magnetic atoms which are the only ones that inter-replica springs are applied to. If the group does not include all magnetic atoms, then non-GNEB magnetic atoms have no inter-replica springs and the torques they feel and their precession motion is computed in the usual way due only to other magnetic atoms within their replica. Conceptually, the non-GNEB atoms provide a background force field for the GNEB atoms. Their magnetic spins can be allowed to evolve during the GNEB minimization procedure.

The initial spin configuration for each of the replicas can be specified in different manners via the file-style setting, as discussed below. Only atomic spins whose initial coordinates should differ from the current configuration need to be specified.

Conceptually, the initial and final configurations for the first replica should be states on either side of an energy barrier.

As explained below, the initial configurations of intermediate replicas can be spin coordinates interpolated in a linear fashion between the first and last replicas. This is often adequate for simple transitions. For more complex transitions, it may lead to slow convergence or even bad results if the minimum energy path (MEP, see below) of states over the barrier cannot be correctly converged to from such an initial path. In this case, you will want to generate initial states for the intermediate replicas that are geometrically closer to the MEP and read them in.

For a file-style setting of final, a filename is specified which contains atomic and spin coordinates for zero or more atoms, in the format described below. For each atom that appears in the file, the new coordinates are assigned to that atom in the final replica. Each intermediate replica also assigns a new spin to that atom in an interpolated manner. This is done by using the current direction of the spin at the starting point and the read-in direction as the final point. The “angular distance” between them is calculated, and the new direction is assigned to be a fraction of the angular distance.

Note: The “angular distance” between the starting and final point is evaluated in the geodesic sense, as described in (BessarabA).

Note: The angular interpolation between the starting and final point is achieved using Rodrigues formula:

\[
\vec{m}_i^\nu = \vec{m}_i^f \cos(\omega_i^\nu) + (\vec{k}_i \times \vec{m}_i^f) \sin(\omega_i^\nu) + (1.0 - \cos(\omega_i^\nu))\vec{k}_i (\vec{k}_i \cdot \vec{m}_i^f)
\]

where \(\vec{m}_i^f\) is the initial spin configuration for spin i, \(\omega_i^\nu\) is a rotation angle defined as:

\[
\omega_i^\nu = (\nu - 1)\Delta \omega_i \quad \text{and} \quad \Delta \omega_i = \frac{\omega_i}{Q - 1}
\]

with \(\nu\) the image number, Q the total number of images, and \(\omega_i\) the total rotation between the initial and final spins. \(\vec{k}_i\) defines a rotation axis such as:

\[
\vec{k}_i = \frac{\vec{m}_i^f \times \vec{m}_i^f}{|\vec{m}_i^f \times \vec{m}_i^f|}
\]
if the initial and final spins are not aligned. If the initial and final spins are aligned, then their cross product is null, and the expression above does not apply. If they point toward the same direction, the intermediate images conserve the same orientation. If the initial and final spins are aligned, but point toward opposite directions, an arbitrary rotation vector belonging to the plane perpendicular to initial and final spins is chosen. In this case, a warning message is displayed.

For a file-style setting of each, a filename is specified which is assumed to be unique to each replica. See the neb documentation page for more information about this option.

For a file-style setting of none, no filename is specified. Each replica is assumed to already be in its initial configuration at the time the neb command is issued. This allows each replica to define its own configuration by reading a replica-specific data or restart or dump file, via the read_data, read_restart, or read_dump commands. The replica-specific names of these files can be specified as in the discussion above for the each file-style. Also see the section below for how a NEB calculation can produce restart files, so that a long calculation can be restarted if needed.

**Note:** None of the file-style settings change the initial configuration of any atom in the first replica. The first replica must thus be in the correct initial configuration at the time the neb command is issued.

A NEB calculation proceeds in two stages, each of which is a minimization procedure. To enable this, you must first define a min_style, using either the spin, spin/cg, or spin/lbfgs style (see [min-spin](#) for more information). The other styles cannot be used, since they relax the lattice degrees of freedom instead of the spins.

The minimizer tolerances for energy and force are set by etol and ttol, the same as for the minimize command.

A non-zero etol means that the GNEB calculation will terminate if the energy criterion is met by every replica. The energies being compared to etol do not include any contribution from the inter-replica nudging forces, since these are non-conservative. A non-zero ttol means that the GNEB calculation will terminate if the torque criterion is met by every replica. The torques being compared to ttol include the inter-replica nudging forces.

The maximum number of iterations in each stage is set by N1 and N2. These are effectively timestep counts since each iteration of damped dynamics is like a single timestep in a dynamics run. During both stages, the potential energy of each replica and its normalized distance along the reaction path (reaction coordinate RD) will be printed to the screen and log file every Nevery timesteps. The RD is 0 and 1 for the first and last replica. For intermediate replicas, it is the cumulative angular distance (normalized by the total cumulative angular distance) between adjacent replicas, where “distance” is defined as the length of the 3N-vector of the geodesic distances in spin coordinates, with N the number of GNEB spins involved (see equation (13) in ([Bessarab](#))). These outputs allow you to monitor NEB’s progress in finding a good energy barrier. N1 and N2 must both be multiples of Nevery.

In the first stage of GNEB, the set of replicas should converge toward a minimum energy path (MEP) of conformational states that transition over a barrier. The MEP for a transition is defined as a sequence of 3N-dimensional spin states, each of which has a potential energy gradient parallel to the MEP itself. The configuration of highest energy along a MEP corresponds to a saddle point. The replica states will also be roughly equally spaced along the MEP due to the inter-replica nudging force added by the fix neb command.

In the second stage of GNEB, the replica with the highest energy is selected and the inter-replica forces on it are converted to a force that drives its spin coordinates to the top or saddle point of the barrier, via the barrier-climbing calculation described in ([Bessarab](#)). As before, the other replicas rearrange themselves along the MEP so as to be roughly equally spaced.

When both stages are complete, if the GNEB calculation was successful, the configurations of the replicas should be along (close to) the MEP and the replica with the highest energy should be a spin configuration at (close to) the saddle point of the transition. The potential energies for the set of replicas represents the energy profile of the transition along the MEP.

An atom map must be defined which it is not by default for atom_style atomic problems. The atom_modify map command can be used to do this.
An initial value can be defined for the timestep. Although, the spin minimization algorithm is an adaptive timestep methodology, so that this timestep is likely to evolve during the calculation.

The minimizers in LAMMPS operate on all spins in your system, even non-GNEB atoms, as defined above.

Each file read by the neb/spin command containing spin coordinates used to initialize one or more replicas must be formatted as follows.

The file can be ASCII text or a gzipped text file (detected by a .gz suffix). The file can contain initial blank lines or comment lines starting with “#” which are ignored. The first non-blank, non-comment line should list N = the number of lines to follow. The N successive lines contain the following information:

```
ID1 g1 x1 y1 z1 sx1 sy1 sz1
ID2 g2 x2 y2 z2 sx2 sy2 sz2
... 
IDN gN yN zN sxN syN szN
```

The fields are the atom ID, the norm of the associated magnetic spin, followed by the x,y,z coordinates and the sx,sy,sz spin coordinates. The lines can be listed in any order. Additional trailing information on the line is OK, such as a comment.

Note that for a typical GNEB calculation you do not need to specify initial spin coordinates for very many atoms to produce differing starting and final replicas whose intermediate replicas will converge to the energy barrier. Typically only new spin coordinates for atoms geometrically near the barrier need be specified.

Also note there is no requirement that the atoms in the file correspond to the GNEB atoms in the group defined by the fix neb command. Not every GNEB atom need be in the file, and non-GNEB atoms can be listed in the file.

Four kinds of output can be generated during a GNEB calculation: energy barrier statistics, thermodynamic output by each replica, dump files, and restart files.

When running with multiple partitions (each of which is a replica in this case), the print-out to the screen and master log.lammps file contains a line of output, printed once every Nevery timesteps. It contains the timestep, the maximum torque per replica, the maximum torque per atom (in any replica), potential gradients in the initial, final, and climbing replicas, the forward and backward energy barriers, the total reaction coordinate (RDT), and the normalized reaction coordinate and potential energy of each replica.

The “maximum torque per replica” is the two-norm of the 3N-length vector given by the cross product of a spin by its precession vector omega, maximized across replicas, which is what the tol setting is checking against. In this case, N is all the atoms in each replica. The “maximum torque per atom” is the maximum torque component of any atom in any replica. The potential gradients are the two-norm of the 3N-length magnetic precession vector solely due to the interaction potential i.e. without adding in inter-replica forces, and projected along the path tangent (as detailed in Appendix D of (BessarabA)).

The “reaction coordinate” (RD) for each replica is the two-norm of the 3N-length vector of geodesic distances between its spins and the preceding replica’s spins (see equation (13) of (BessarabA)), added to the RD of the preceding replica. The RD of the first replica RD1 = 0.0; the RD of the final replica RDN = RDT, the total reaction coordinate. The normalized RDs are divided by RDT, so that they form a monotonically increasing sequence from zero to one. When computing RD, N only includes the spins being operated on by the fix neb/spin command.

The forward (reverse) energy barrier is the potential energy of the highest replica minus the energy of the first (last) replica.

Supplementary information for all replicas can be printed out to the screen and master log.lammps file by adding the verbose keyword. This information include the following. The “GradVidottan” are the projections of the potential gradient for the replica i on its tangent vector (as detailed in Appendix D of (BessarabA)). The “DNi” are the non
normalized geodesic distances (see equation (13) of (BessarabA)), between a replica i and the next replica i+1. For the last replica, this distance is not defined and a “NAN” value is the corresponding output.

When a NEB calculation does not converge properly, the supplementary information can help understanding what is going wrong.

When running on multiple partitions, LAMMPS produces additional log files for each partition, e.g. log.lammps.0, log.lammps.1, etc. For a GNEB calculation, these contain the thermodynamic output for each replica.

If dump commands in the input script define a filename that includes a universe or uloop style variable, then one dump file (per dump command) will be created for each replica. At the end of the GNEB calculation, the final snapshot in each file will contain the sequence of snapshots that transition the system over the energy barrier. Earlier snapshots will show the convergence of the replicas to the MEP.

Likewise, restart filenames can be specified with a universe or uloop style variable, to generate restart files for each replica. These may be useful if the GNEB calculation fails to converge properly to the MEP, and you wish to restart the calculation from an intermediate point with altered parameters.

A c file script in provided in the tool/spin/interpolate_gneb directory, that interpolates the MEP given the information provided by the verbose output option (as detailed in Appendix D of (BessarabA)).

### 16.88.4 Restrictions

This command can only be used if LAMMPS was built with the SPIN package. See the Build package doc page for more info.

For magnetic GNEB calculations, only the spin_none value for the line keyword can be used when minimization styles spin/cg and spin/lbfgs are employed.

### 16.88.5 Related commands

* min/spin, fix neb/spin

### 16.88.6 Default

### 16.89 neigh_modify command

#### 16.89.1 Syntax

{nigh_modify} keyword values ...

- one or more keyword/value pairs may be listed
keyword = delay or every or check or once or cluster or include or exclude or page...
→ or one or binsize or collection/type or collection/interval

delay value = N
N = delay building until this many steps since last build
every value = M
M = build neighbor list every this many steps
check value = yes or no
yes = only build if some atom has moved half the skin distance or more
no = always build on 1st step that every and delay are satisfied
once
yes = only build neighbor list once at start of run and never rebuild
no = rebuild neighbor list according to other settings
cluster
yes = check bond, angle, etc neighbor list for nearby clusters
no = do not check bond, angle, etc neighbor list for nearby clusters
include value = group-ID
group-ID = only build pair neighbor lists for atoms in this group
exclude values:
type M N
M, N = exclude if one atom in pair is type M, other is type N
group group1-ID group2-ID
group1-ID, group2-ID = exclude if one atom is in 1st group, other in 2nd
molecule/intra group-ID
molecule/intra group-ID = exclude if both atoms are in the same molecule and in group
molecule/inter group-ID
molecule/inter group-ID = exclude if both atoms are in different molecules and in group
none
delete all exclude settings
page value = N
N = number of pairs stored in a single neighbor page
one value = N
N = max number of neighbors of one atom
binsize value = size
size = bin size for neighbor list construction (distance units)
collection/type values = N arg1 ... argN
N = number of custom collections
arg = N separate lists of types (see below)
collection/interval values = N arg1 ... argN
N = number of custom collections
arg = N separate cutoffs for intervals (see below)

16.89.2 Examples

neigh_modify every 2 delay 10 check yes page 100000
neigh_modify exclude type 2 3
neigh_modify exclude group frozen frozen check no
neigh_modify exclude group residue1 chain3
neigh_modify exclude molecule/intra rigid
neigh_modify collection/type 2 1*2,5 3*4
neigh_modify collection/interval 2 1.0 10.0
16.89.3 Description

This command sets parameters that affect the building and use of pairwise neighbor lists. Depending on what pair interactions and other commands are defined, a simulation may require one or more neighbor lists.

The `every`, `delay`, `check`, and `once` options affect how often lists are built as a simulation runs. The `delay` setting means never build new lists until at least N steps after the previous build. The `every` setting means build lists every M steps (after the delay has passed). If the `check` setting is no, the lists are built on the first step that satisfies the `delay` and `every` settings. If the `check` setting is yes, then the `every` and `delay` settings determine when a build may possibly be performed, but an actual build only occurs if some atom has moved more than half the skin distance (specified in the `neighbor` command) since the last build.

If the `once` setting is yes, then the neighbor list is only built once at the beginning of each run, and never rebuilt, except on steps when a restart file is written, or steps when a fix forces a rebuild to occur (e.g. fixes that create or delete atoms, such as `fix deposit` or `fix evaporate`). This setting should only be made if you are certain atoms will not move far enough that the neighbor list should be rebuilt, e.g. running a simulation of a cold crystal. Note that it is not that expensive to check if neighbor lists should be rebuilt.

When the rRESPA integrator is used (see the `run_style` command), the `every` and `delay` parameters refer to the longest (outermost) timestep.

The `cluster` option does a sanity test every time neighbor lists are built for bond, angle, dihedral, and improper interactions, to check that each set of 2, 3, or 4 atoms is a cluster of nearby atoms. It does this by computing the distance between pairs of atoms in the interaction and insuring they are not further apart than half the periodic box length. If they are, an error is generated, since the interaction would be computed between far-away atoms instead of their nearby periodic images. The only way this should happen is if the pairwise cutoff is so short that atoms that are part of the same interaction are not communicated as ghost atoms. This is an unusual model (e.g. no pair interactions at all) and the problem can be fixed by use of the `comm_modify cutoff` command. Note that to save time, the default `cluster` setting is no, so that this check is not performed.

The `include` option limits the building of pairwise neighbor lists to atoms in the specified group. This can be useful for models where a large portion of the simulation is particles that do not interact with other particles or with each other via pairwise interactions. The group specified with this option must also be specified via the `atom_modify first` command. Note that specifying “all” as the group-ID effectively turns off the `include` option.

The `exclude` option turns off pairwise interactions between certain pairs of atoms, by not including them in the neighbor list. These are sample scenarios where this is useful:

- In crack simulations, pairwise interactions can be shut off between 2 slabs of atoms to effectively create a crack.
- When a large collection of atoms is treated as frozen, interactions between those atoms can be turned off to save needless computation. E.g. Using the `fix setforce` command to freeze a wall or portion of a bio-molecule.
- When one or more rigid bodies are specified, interactions within each body can be turned off to save needless computation. See the `fix rigid` command for more details.

The `exclude type` option turns off the pairwise interaction if one atom is of type M and the other of type N. M can equal N. The `exclude group` option turns off the interaction if one atom is in the first group and the other is the second. Group1-ID can equal group2-ID. The `exclude molecule/intra` option turns off the interaction if both atoms are in the specified group and in the same molecule, as determined by their molecule ID. The `exclude molecule/inter` turns off the interaction between pairs of atoms that have different molecule IDs and are both in the specified group.

Each of the exclude options can be specified multiple times. The `exclude type` option is the most efficient option to use; it requires only a single check, no matter how many times it has been specified. The other exclude options are more expensive if specified multiple times; they require one check for each time they have been specified.

Note that the exclude options only affect pairwise interactions; see the `delete_bonds` command for information on turning off bond interactions.
Note: Excluding pairwise interactions will not work correctly when also using a long-range solver via the \textit{kspace\_style} command. LAMMPS will give a warning to this effect. This is because the short-range pairwise interaction needs to subtract off a term from the total energy for pairs whose short-range interaction is excluded, to compensate for how the long-range solver treats the interaction. This is done correctly for pairwise interactions that are excluded (or weighted) via the \textit{special\_bonds} command. But it is not done for interactions that are excluded via these \textit{neigh\_modify\_exclude} options.

The \textit{page} and \textit{one} options affect how memory is allocated for the neighbor lists. For most simulations the default settings for these options are fine, but if a very large problem is being run or a very long cutoff is being used, these parameters can be tuned. The indices of neighboring atoms are stored in “pages”, which are allocated one after another as they fill up. The size of each page is set by the \textit{page} value. A new page is allocated when the next atom’s neighbors could potentially overflow the list. This threshold is set by the \textit{one} value which tells LAMMPS the maximum number of neighbor’s one atom can have.

Note: LAMMPS can crash without an error message if the number of neighbors for a single particle is larger than the \textit{page} setting, which means it is much, much larger than the \textit{one} setting. This is because LAMMPS does not error check these limits for every pairwise interaction (too costly), but only after all the particle’s neighbors have been found. This problem usually means something is very wrong with the way you have setup your problem (particle spacing, cutoff length, neighbor skin distance, etc). If you really expect that many neighbors per particle, then boost the \textit{one} and \textit{page} settings accordingly.

The \textit{binsize} option allows you to specify what size of bins will be used in neighbor list construction to sort and find neighboring atoms. By default, for \textit{neighbor\_style\_bin}, LAMMPS uses bins that are 1/2 the size of the maximum pair cutoff. For \textit{neighbor\_style\_multi}, the bins are 1/2 the size of the collection interaction cutoff. Typically these are good values for minimizing the time for neighbor list construction. This setting overrides the default. If you make it too big, there is little overhead due to looping over bins, but more atoms are checked. If you make it too small, the optimal number of atoms is checked, but bin overhead goes up. If you set the \textit{binsize} to 0.0, LAMMPS will use the default \textit{binsize} of 1/2 the cutoff.

The \textit{collection/type} option allows you to define collections of atom types, used by the \textit{multi} neighbor mode. By grouping atom types with similar physical size or interaction cutoff lengths, one may be able to improve performance by reducing overhead. You must first specify the number of collections N to be defined followed by N lists of types. Each list consists of a series of type ranges separated by commas. The range can be specified as a single numeric value, or a wildcard asterisk can be used to specify a range of values. This takes the form “*” or “#n” or “#n” or “#m*n”. For example, if \textit{M} = the number of atom types, then an asterisk with no numeric values means all types from 1 to \textit{M}. A leading asterisk means all types from 1 to \textit{n} (inclusive). A trailing asterisk means all types from \textit{n} to \textit{M} (inclusive). A middle asterisk means all types from \textit{m} to \textit{n} (inclusive). Note that all atom types must be included in exactly one of the \textit{N} collections.

The \textit{collection/interval} option provides a similar capability. This command allows a user to define collections by specifying a series of cutoff intervals. LAMMPS will automatically sort atoms into these intervals based on their type-dependent cutoffs or their finite size. You must first specify the number of collections \textit{N} to be defined followed by \textit{N} values representing the upper cutoff of each interval. This command is particularly useful for granular pair styles where the interaction distance of particles depends on their radius and may not depend on their atom type.
16.89.4 Restrictions

If the “delay” setting is non-zero, then it must be a multiple of the “every” setting.
The molecule/intra and molecule/inter exclude options can only be used with atom styles that define molecule IDs.
The value of the page setting must be at least 10x larger than the one setting. This insures neighbor pages are not mostly empty space.

16.89.5 Related commands

neighbor, delete_bonds

16.89.6 Default

The option defaults are delay = 10, every = 1, check = yes, once = no, cluster = no, include = all (same as no include option defined), exclude = none, page = 100000, one = 2000, and binsize = 0.0.

16.90 neighbor command

16.90.1 Syntax

neighbor skin style

- skin = extra distance beyond force cutoff (distance units)
- style = bin or nsq or multi or multi/old

16.90.2 Examples

neighbor 0.3 bin
neighbor 2.0 nsq

16.90.3 Description

This command sets parameters that affect the building of pairwise neighbor lists. All atom pairs within a neighbor cutoff distance equal to the their force cutoff plus the skin distance are stored in the list. Typically, the larger the skin distance, the less often neighbor lists need to be built, but more pairs must be checked for possible force interactions every timestep. The default value for skin depends on the choice of units for the simulation; see the default values below.

The skin distance is also used to determine how often atoms migrate to new processors if the check option of the neigh_modify command is set to yes. Atoms are migrated (communicated) to new processors on the same timestep that neighbor lists are re-built.

The style value selects what algorithm is used to build the list. The bin style creates the list by binning which is an operation that scales linearly with N/P, the number of atoms per processor where N = total number of atoms and P = number of processors. It is almost always faster than the nsq style which scales as (N/P)^2. For unsolvated small molecules in a non-periodic box, the nsq choice can sometimes be faster. Either style should give the same answers.
The *multi* style is a modified binning algorithm that is useful for systems with a wide range of cutoff distances, e.g. due to different size particles. For granular pair styles, cutoffs are set to the sum of the maximum atomic radii for each atom type. For the *bin* style, the bin size is set to 1/2 of the largest cutoff distance between any pair of atom types and a single set of bins is defined to search over for all atom types. This can be inefficient if one pair of types has a very long cutoff, but other type pairs have a much shorter cutoff. The *multi* style uses different sized bins for collections of different sized particles, where “size” may mean the physical size of the particle or its cutoff distance for interacting with other particles. Different sets of bins are then used to construct the neighbor lists as as further described by Shire, Hanley, and Stratford (*Shire*). This imposes some extra setup overhead, but the searches themselves may be much faster. By default, each atom type defines a separate collection of particles. For systems where two or more atom types have the same size (either physical size or cutoff distance), the definition of collections can be customized, which can result in less overhead and faster performance. See the *neigh_modify* command for how to define custom collections. Whether the collection definition is customized or not, also see the *comm_modify mode multi* command for communication options that further improve performance in a manner consistent with neighbor style multi.

An alternate style, *multi/old*, sets the bin size to 1/2 of the shortest cutoff distance and multiple sets of bins are defined to search over for different atom types. This algorithm used to be the default *multi* algorithm in LAMMPS but was found to be significantly slower than the new approach. For now we are keeping the old option in case there are use cases where multi/old outperforms the new multi style.

The *neigh_modify* command has additional options that control how often neighbor lists are built and which pairs are stored in the list.

When a run is finished, counts of the number of neighbors stored in the pairwise list and the number of times neighbor lists were built are printed to the screen and log file. See the *Run output* page for details.

- 0.1 bin for units = cgs, skin = 0.1 cm = 1.0 mm

16.91 newton command

16.91.1 Syntax

newton flag
newton flag1 flag2

- flag = on or off for both pairwise and bonded interactions
- flag1 = on or off for pairwise interactions
- flag2 = on or off for bonded interactions

16.91.2 Examples

newton off
newton on off

16.91.3 Description

This command turns Newton’s third law on or off for pairwise and bonded interactions. For most problems, setting Newton’s third law to on means a modest savings in computation at the cost of two times more communication. Whether this is faster depends on problem size, force cutoff lengths, a machine’s compute/communication ratio, and how many processors are being used.

Setting the pairwise newton flag to off means that if two interacting atoms are on different processors, both processors compute their interaction and the resulting force information is not communicated. Similarly, for bonded interactions, newton off means that if a bond, angle, dihedral, or improper interaction contains atoms on 2 or more processors, the interaction is computed by each processor.

LAMMPS should produce the same answers for any newton flag settings, except for round-off issues.

With run_style respa and only bonded interactions (bond, angle, etc) computed in the innermost timestep, it may be faster to turn newton off for bonded interactions, to avoid extra communication in the innermost loop.

16.91.4 Restrictions

The newton bond setting cannot be changed after the simulation box is defined by a read_data or create_box command.

```
next variables
```

- variables = one or more variable names

16.92.2 Examples

```
next x
next a t x myTemp
```

16.92.3 Description

This command is used with variables defined by the `variable` command. It assigns the next value to the variable from the list of values defined for that variable by the `variable` command. Thus when that variable is subsequently substituted for in an input script command, the new value is used.

See the `variable` command for info on how to define and use different kinds of variables in LAMMPS input scripts. If a variable name is a single lower-case character from “a” to “z”, it can be used in an input script command as $a or $z. If it is multiple letters, it can be used as ${myTemp}.

If multiple variables are used as arguments to the `next` command, then all must be of the same variable style: `index`, `loop`, `file`, `universe`, or `uloop`. An exception is that `universe-` and `uloop-style` variables can be mixed in the same `next` command.

All the variables specified with the next command are incremented by one value from their respective list of values. A `file-style` variable reads the next line from its associated file. An `atomfile-style` variable reads the next set of lines (one per atom) from its associated file. `String-`, `atom-`, `equal-`, or `world-style` variables cannot be used with the next command, since they only store a single value.

When any of the variables in the next command has no more values, a flag is set that causes the input script to skip the next `jump` command encountered. This enables a loop containing a next command to exit. As explained in the `variable` command, the variable that has exhausted its values is also deleted. This allows it to be used and re-defined later in the input script. `File-style` and `atomfile-style` variables are exhausted when the end-of-file is reached.

When the next command is used with `index-` or `loop-style` variables, the next value is assigned to the variable for all processors. When the next command is used with `file-style` variables, the next line is read from its file and the string assigned to the variable. When the next command is used with `atomfile-style` variables, the next set of per-atom values is read from its file and assigned to the variable.

When the next command is used with `universe-` or `uloop-style` variables, all `universe-` or `uloop-style` variables must be listed in the next command. This is because of the manner in which the incrementing is done, using a single lock file for all variables. The next value (for each variable) is assigned to whichever processor partition executes the command first. All processors in the partition are assigned the same value(s). Running LAMMPS on multiple partitions of processors via the `-partition command-line switch`. `Universe-` and `uloop-style` variables are incremented using the files
“tmp.lammps.variable” and “tmp.lammps.variable.lock” which you will see in your directory during and after such a LAMMPS run.

Here is an example of running a series of simulations using the next command with an index-style variable. If this input script is named in.polymer, 8 simulations would be run using data files from directories run1 through run8.

```
variable d index run1 run2 run3 run4 run5 run6 run7 run8
shell cd $d
read_data data.polymer
run 10000
shell cd ..
clear
next d
jump in.polymer
```

If the variable “d” were of style universe, and the same in.polymer input script were run on 3 partitions of processors, then the first 3 simulations would begin, one on each set of processors. Whichever partition finished first, it would assign variable “d” the fourth value and run another simulation, and so forth until all 8 simulations were finished.

Jump and next commands can also be nested to enable multi-level loops. For example, this script will run 15 simulations in a double loop.

```
variable i loop 3
  variable j loop 5
  clear
  ...
  read_data data.polymer.$i$j
  print Running simulation $i.$j
  run 10000
  next j
  jump in.script
next i
jump in.script
```

Here is an example of a double loop which uses the if and jump commands to break out of the inner loop when a condition is met, then continues iterating through the outer loop.

```
label loopa
variable a loop 5
label loopb
variable b loop 5
print "A,B = $a,$b"
run 10000
if $b > 2 then "jump in.script break"
next b
jump in.script loopb
label break
variable b delete
next a
jump in.script loopa
```
16.92.4 Restrictions

```

### 16.93.3 Description

This command invokes package-specific settings for the various accelerator packages available in LAMMPS. Currently the following packages use settings from this command: GPU, INTEL, KOKKOS, and OPENMP.

If this command is specified in an input script, it must be near the top of the script, before the simulation box has been defined. This is because it specifies settings that the accelerator packages use in their initialization, before a simulation is defined.

This command can also be specified from the command-line when launching LAMMPS, using the “-pk” command-line switch. The syntax is exactly the same as when used in an input script.

Note that all of the accelerator packages require the package command to be specified (except the OPT package), if the package is to be used in a simulation (LAMMPS can be built with an accelerator package without using it in a particular simulation). However, in all cases, a default version of the command is typically invoked by other accelerator settings.

The KOKKOS package requires a “-k on” command-line switch respectively, which invokes a “package kokkos” command with default settings.
For the GPU, INTEL, and OPENMP packages, if a “-sf gpu” or “-sf intel” or “-sf omp” command-line switch is used to auto-append accelerator suffixes to various styles in the input script, then those switches also invoke a “package gpu”, “package intel”, or “package omp” command with default settings.

Note: A package command for a particular style can be invoked multiple times when a simulation is setup, e.g. by the \_c on, \_k on, \_sf, and \_pk command-line switches, and by using this command in an input script. Each time it is used all of the style options are set, either to default values or to specified settings. I.e. settings from previous invocations do not persist across multiple invocations.

See the Accelerator packages page for more details about using the various accelerator packages for speeding up LAMMPS simulations.

The \_g pu style invokes settings associated with the use of the GPU package.

The \_Ng pu argument sets the number of GPUs per node. If \_Ng pu is 0 and no other keywords are specified, GPU or accelerator devices are auto-selected. In this process, all platforms are searched for accelerator devices and GPUs are chosen if available. The device with the highest number of compute cores is selected. The number of devices is increased to be the number of matching accelerators with the same number of compute cores. If there are more devices than MPI tasks, the additional devices will be unused. The auto-selection of GPUs/accelerator devices and platforms can be restricted by specifying a non-zero value for \_Ng pu and / or using the \_gpuID, \_platform, and \_device_type keywords as described below. If there are more MPI tasks (per node) than GPUs, multiple MPI tasks will share each GPU.

Optional keyword/value pairs can also be specified. Each has a default value as listed below.

The \_neigh keyword specifies where neighbor lists for pair style computation will be built. If \_neigh is \_y es, which is the default, neighbor list building is performed on the GPU. If \_neigh is \_n o, neighbor list building is performed on the CPU. GPU neighbor list building currently cannot be used with a triclinic box. GPU neighbor lists are not compatible with commands that are not GPU-enabled. When a non-GPU enabled command requires a neighbor list, it will also be built on the CPU. In these cases, it will typically be more efficient to only use CPU neighbor list builds.

The \_newton keyword sets the Newton flags for pairwise (not bonded) interactions to \_o ff or \_o n, the same as the \_newton command allows. Currently, only an \_o ff value is allowed, since all the GPU package pair styles require this setting. This means more computation is done, but less communication. In the future a value of \_o n may be allowed, so the \_newton keyword is included as an option for compatibility with the package command for other accelerator styles. Note that the newton setting for bonded interactions is not affected by this keyword.

The \_pair/\_o nly keyword can change how any “gpu” suffix is applied. By default a suffix is applied to all styles for which an accelerated variant is available. However, that is not always the most effective way to use an accelerator. With \_pair/\_o nly set to \_o n the suffix will only by applied to supported pair styles, which tend to be the most effective in using an accelerator and their operation can be overlapped with all other computations on the CPU.

The \_binsize keyword sets the size of bins used to bin atoms in neighbor list builds performed on the GPU, if \_neigh = \_y es is set. If \_binsize is set to 0.0 (the default), then the binsize is set automatically using heuristics in the GPU package.

The \_split keyword can be used for load balancing force calculations between CPU and GPU cores in GPU-enabled pair styles. If 0 < \_split < 1.0, a fixed fraction of particles is offloaded to the GPU while force calculation for the other particles occurs simultaneously on the CPU. If \_split < 0.0, the optimal fraction (based on CPU and GPU timings) is calculated every 25 timesteps, i.e. dynamic load-balancing across the CPU and GPU is performed. If \_split = 1.0, all force calculations for GPU accelerated pair styles are performed on the GPU. In this case, other \_hybrid pair interactions, \_bond, \_angle, \_dihedral, \_improper, and \_l ong-range calculations can be performed on the CPU while the GPU is performing force calculations for the GPU-enabled pair style. If all CPU force computations complete before the GPU completes, LAMMPS will block until the GPU has finished before continuing the timestep.

As an example, if you have two GPUs per node and 8 CPU cores per node, and would like to run on 4 nodes (32 cores) with dynamic balancing of force calculation across CPU and GPU cores, you could specify
mpirun -np 32 -sf gpu -in in.script  # launch command
package gpu 2 split -1          # input script command

In this case, all CPU cores and GPU devices on the nodes would be utilized. Each GPU device would be shared by 4 CPU cores. The CPU cores would perform force calculations for some fraction of the particles at the same time the GPUs performed force calculation for the other particles.

The `gpuID` keyword is used to specify the first ID for the GPU or other accelerator that LAMMPS will use. For example, if the ID is 1 and `Ngpu` is 3, GPUs 1-3 will be used. Device IDs should be determined from the output of `nvc_get_devices`, `ocl_get_devices`, or `hip_get_devices` as provided in the `lib/gpu` directory. When using OpenCL with accelerators that have main memory NUMA, the accelerators can be split into smaller virtual accelerators for more efficient use with MPI.

The `tpa` keyword sets the number of GPU vector lanes per atom used to perform force calculations. With a default value of 1, the number of lanes will be chosen based on the pair style, however, the value can be set explicitly with this keyword to fine-tune performance. For large cutoffs or with a small number of particles per GPU, increasing the value can improve performance. The number of lanes per atom must be a power of 2 and currently cannot be greater than the SIMD width for the GPU / accelerator. In the case it exceeds the SIMD width, it will automatically be decreased to meet the restriction.

The `blocksize` keyword allows you to tweak the number of threads used per thread block. This number should be a multiple of 32 (for GPUs) and its maximum depends on the specific GPU hardware. Typical choices are 64, 128, or 256. A larger block size increases occupancy of individual GPU cores, but reduces the total number of thread blocks, thus may lead to load imbalance. On modern hardware, the sensitivity to the blocksize is typically low.

The `Nthreads` value for the `omp` keyword sets the number of OpenMP threads allocated for each MPI task. This setting controls OpenMP parallelism only for routines run on the CPUs. For more details on setting the number of OpenMP threads, see the discussion of the `Nthreads` setting on this page for the “package omp” command. The meaning of `Nthreads` is exactly the same for the GPU, INTEL, and GPU packages.

The `platform` keyword is only used with OpenCL to specify the ID for an OpenCL platform. See the output from `ocl_get_devices` in the `lib/gpu` directory. In LAMMPS only one platform can be active at a time and by default (id=-1) the platform is auto-selected to find the GPU with the most compute cores. When `Ngpu` or other keywords are specified, the auto-selection is appropriately restricted. For example, if `Ngpu` is 3, only platforms with at least 3 accelerators are considered. Similar restrictions can be enforced by the `gpuID` and `device_type` keywords.

The `device_type` keyword can be used for OpenCL to specify the type of GPU to use or specify a custom configuration for an accelerator. In most cases this selection will be automatic and there is no need to use the keyword. The `applegpu` type is not specific to a particular GPU vendor, but is separate due to the more restrictive Apple OpenCL implementation. For expert users, to specify a custom configuration, the `custom` keyword followed by the next parameters can be specified:

```
CONFIG_ID, SIMD_SIZE, MEM_THREADS, SHUFFLE_AVAIL, FAST_MATH, THREADS_PER_ATOM, THREADS_PER_CHARGE, THREADS_PER_THREE, BLOCKPAIR, BLOCK_BIO_PAIR, BLOCK_ELLIPSE, PPPM_BLOCK_1D, BLOCK_NBOR_BUILD, BLOCK_CELL_2D, BLOCK_CELL_ID, MAX_SHARED_TYPES, MAX_BIO_SHARED_TYPES, PPPM_MAX_SPLINE.
```

`CONFIG_ID` can be 0. `SHUFFLE_AVAIL` in {0,1} indicates that inline-PTX (NVIDIA) or OpenCL extensions (Intel) should be used for horizontal vector operations. `FAST_MATH` in {0,1} indicates that OpenCL fast math optimizations are used during the build and hardware-accelerated transcendental functions are used when available. `THREADS_PER_*` give the default `tpa` values for ellipsoidal models, styles using charge, and any other styles. The `BLOCK_*` parameters specify the block sizes for various kernel calls and the `MAX_*SHARED_*` parameters are used to determine the amount of local shared memory to use for storing model parameters.

For OpenCL, the routines are compiled at runtime for the specified GPU or accelerator architecture. The `ocl_args` keyword can be used to specify additional flags for the runtime build.
The intel style invokes settings associated with the use of the INTEL package. All of its settings, except the omp and mode keywords, are ignored if LAMMPS was not built with Xeon Phi co-processor support. All of its settings, including the omp and mode keyword are applicable if LAMMPS was built with co-processor support.

The Nphi argument sets the number of co-processors per node. This can be set to any value, including 0, if LAMMPS was not built with co-processor support.

Optional keyword/value pairs can also be specified. Each has a default value as listed below.

The Nthreads value for the omp keyword sets the number of OpenMP threads allocated for each MPI task. This setting controls OpenMP parallelism only for routines run on the CPUs. For more details on setting the number of OpenMP threads, see the discussion of the Nthreads setting on this page for the “package omp” command. The meaning of Nthreads is exactly the same for the GPU, INTEL, and GPU packages.

The mode keyword determines the precision mode to use for computing pair style forces, either on the CPU or on the co-processor, when using a INTEL supported pair style. It can take a value of single, mixed which is the default, or double. Single means single precision is used for the entire force calculation. Mixed means forces between a pair of atoms are computed in single precision, but accumulated and stored in double precision, including storage of forces, torques, energies, and virial quantities. Double means double precision is used for the entire force calculation.

The lrt keyword can be used to enable “Long Range Thread (LRT)” mode. It can take a value of yes to enable and no to disable. LRT mode generates an extra thread (in addition to any OpenMP threads specified with the OMP_NUM_THREADS environment variable or the omp keyword). The extra thread is dedicated for performing part of the PPPM solver computations and communications. This can improve parallel performance on processors supporting Simultaneous Multithreading (SMT) such as Hyper-Threading (HT) on Intel processors. In this mode, one additional thread is generated per MPI process. LAMMPS will generate a warning in the case that more threads are used than available in SMT hardware on a node. If the PPPM solver from the INTEL package is not used, then the LRT setting is ignored and no extra threads are generated. Enabling LRT will replace the run_style with the verlet/lrt/intel style that is identical to the default verlet style aside from supporting the LRT feature. This feature requires setting the pre-processor flag -DLMP_INTEL_USELRT in the makefile when compiling LAMMPS.

The balance keyword sets the fraction of pair style work offloaded to the co-processor for split values between 0.0 and 1.0 inclusive. While this fraction of work is running on the co-processor, other calculations will run on the host, including neighbor and pair calculations that are not offloaded, as well as angle, bond, dihedral, kspace, and some MPI communications. If split is set to -1, the fraction of work is dynamically adjusted automatically throughout the run. This typically give performance within 5 to 10 percent of the optimal fixed fraction.

The ghost keyword determines whether or not ghost atoms, i.e. atoms at the boundaries of processor sub-domains, are offloaded for neighbor and force calculations. When the value = “no”, ghost atoms are not offloaded. This option can reduce the amount of data transfer with the co-processor and can also overlap MPI communication of forces with computation on the co-processor when the newton pair setting is “on”. When the value = “yes”, ghost atoms are offloaded. In some cases this can provide better performance, especially if the balance fraction is high.

The tpc keyword sets the max # of co-processor threads Ntpc that will run on each core of the co-processor. The default value = 4, which is the number of hardware threads per core supported by the current generation Xeon Phi chips.

The tptask keyword sets the max # of co-processor threads (Ntptask* assigned to each MPI task. The default value = 240, which is the total # of threads an entire current generation Xeon Phi chip can run (240 = 60 cores * 4 threads/core). This means each MPI task assigned to the Phi will enough threads for the chip to run the max allowed, even if only 1 MPI task is assigned. If 8 MPI tasks are assigned to the Phi, each will run with 30 threads. If you wish to limit the number of threads per MPI task, set tptask to a smaller value. E.g. for tptask = 16, if 8 MPI tasks are assigned, each will run with 16 threads, for a total of 128.

Note that the default settings for tpc and tptask are fine for most problems, regardless of how many MPI tasks you assign to a Phi.

The no_affinity keyword will turn off automatic setting of core affinity for MPI tasks and OpenMP threads on the host when using offload to a co-processor. Affinity settings are used when possible to prevent MPI tasks and OpenMP threads
from being on separate NUMA domains and to prevent offload threads from interfering with other processes/threads used for LAMMPS.

The *kokkos* style invokes settings associated with the use of the KOKKOS package.

All of the settings are optional keyword/value pairs. Each has a default value as listed below.

The *neigh* keyword determines how neighbor lists are built. A value of *half* uses a thread-safe variant of half-neighbor lists, the same as used by most pair styles in LAMMPS, which is the default when running on CPUs (i.e. the Kokkos CUDA back end is not enabled).

A value of *full* uses a full neighbor lists and is the default when running on GPUs. This performs twice as much computation as the *half* option, however that is often a win because it is thread-safe and does not require atomic operations in the calculation of pair forces. For that reason, *full* is the default setting for GPUs. However, when running on CPUs, a *half* neighbor list is the default because it is often faster, just as it is for non-accelerated pair styles. Similarly, the *neigh/qeq* keyword determines how neighbor lists are built for *fix qeq/reaxff/kk*.

If the *neigh/thread* keyword is set to off, then the KOKKOS package threads only over atoms. However, for small systems, this may not expose enough parallelism to keep a GPU busy. When this keyword is set to on, the KOKKOS package threads over both atoms and neighbors of atoms. When using *neigh/thread on*, a full neighbor list must also be used. Using *neigh/thread on* may be slower for large systems, so this this option is turned on by default only when there are 16K atoms or less owned by an MPI rank and when using a full neighbor list. Not all KOKKOS-enabled potentials support this keyword yet, and only thread over atoms. Many simple pairwise potentials such as Lennard-Jones do support threading over both atoms and neighbors.

If the *neigh/transpose* keyword is set to off, then the KOKKOS package will use the same memory layout for building the neighbor list on GPUs as used for the pair style. When this keyword is set to on, it will use a different (transposed) memory layout to build the neighbor list on GPUs. This can be faster in some cases (e.g. ReaxFF HNS benchmark) but slower in others (e.g. Lennard Jones benchmark). The copy between different memory layouts is done out of place and therefore doubles the memory overhead of the neighbor list, which can be significant.

The *newton* keyword sets the Newton flags for pairwise and bonded interactions to off or on, the same as the *newton* command allows. The default for GPUs is off because this will almost always give better performance for the KOKKOS package. This means more computation is done, but less communication. However, when running on CPUs a value of on is the default since it can often be faster, just as it is for non-accelerated pair styles.

The *binsize* keyword sets the size of bins used to bin atoms during neighbor list builds. The same value can be set by the *neigh_modify binsize* command. Making it an option in the package kokkos command allows it to be set from the command line. The default value for CPUs is 0.0, which means the LAMMPS default will be used, which is bins = 1/2 the size of the pairwise cutoff + neighbor skin distance. This is fine when neighbor lists are built on the CPU. For GPU builds, a 2x larger binsize equal to the pairwise cutoff + neighbor skin is often faster, which is the default. Note that if you use a longer-than-usual pairwise cutoff, e.g. to allow for a smaller fraction of KSpace work with a long-range Coulombic solver because the GPU is faster at performing pairwise interactions, then this rule of thumb may give too large a binsize and the default should be overridden with a smaller value.

The *comm* and *comm/exchange* and *comm/forward* and *comm/pair/forward* and *comm/fix/forward* and *comm/reverse* keywords determine whether the host or device performs the packing and unpacking of data when communicating per-atom data between processors. “Exchange” communication happens only on timesteps that neighbor lists are rebuilt. The data is only for atoms that migrate to new processors. “Forward” communication happens every timestep. “Reverse” communication happens every timestep if the *newton* option is on. The data is for atom coordinates and any other atom properties that needs to be updated for ghost atoms owned by each processor. “Pair/comm” controls additional communication in pair styles, such as *pair_style* EAM. “Fix/comm” controls additional communication in fixes, such as fix SHAKE.

The *comm* keyword is simply a short-cut to set the same value for all the *comm* keywords.

The value options for the keywords are no or host or device. A value of no means to use the standard non-KOKKOS method of packing/unpacking data for the communication. A value of host means to use the host, typically a multi-
core CPU, and perform the packing/unpacking in parallel with threads. A value of `device` means to use the device, typically a GPU, to perform the packing/unpacking operation. If a value of `host` is used for the `comm/pair/forward` or `comm/fix/forward` keyword, it will be automatically be changed to `no` since these keywords don’t support `host` mode.

The optimal choice for these keywords depends on the input script and the hardware used. The `no` value is useful for verifying that the Kokkos-based `host` and `device` values are working correctly. It is the default when running on CPUs since it is usually the fastest.

When running on CPUs or Xeon Phi, the `host` and `device` values work identically. When using GPUs, the `device` value is the default since it will typically be optimal if all of your styles used in your input script are supported by the KOKKOS package. In this case data can stay on the GPU for many timesteps without being moved between the host and GPU, if you use the `device` value. If your script uses styles (e.g. fixes) which are not yet supported by the KOKKOS package, then data has to be moved between the host and device anyway, so it is typically faster to let the host handle communication, by using the `host` value. Using `host` instead of `no` will enable use of multiple threads to pack/unpack communicated data. When running small systems on a GPU, performing the exchange pack/unpack on the host CPU can give speedup since it reduces the number of CUDA kernel launches.

The `gpu/aware` keyword chooses whether GPU-aware MPI will be used. When this keyword is set to `on`, buffers in GPU memory are passed directly through MPI send/receive calls. This reduces overhead of first copying the data to the host CPU. However GPU-aware MPI is not supported on all systems, which can lead to segmentation faults and would require using a value of `off`. If LAMMPS can safely detect that GPU-aware MPI is not available (currently only possible with OpenMPI v2.0.0 or later), then the `gpu/aware` keyword is automatically set to `off` by default. When the `gpu/aware` keyword is set to `off` while any of the `comm` keywords are set to `device`, the value for these `comm` keywords will be automatically changed to `no`. This setting has no effect if not running on GPUs or if using only one MPI rank. GPU-aware MPI is available for OpenMPI 1.8 (or later versions), Mvapich2 1.9 (or later) when the “MV2_USE_CUDA” environment variable is set to “1”. CrayMPI, and IBM Spectrum MPI when the “-gpu” flag is used.

The `pair/only` keyword can change how the KOKKOS suffix “kk” is applied when using an accelerator device. By default device acceleration is always used for all available styles. With `pair/only` set to `on` the suffix setting will choose device acceleration only for pair styles and run all other force computations on the host CPU. The `comm` flags will also automatically be changed to `no`. This can result in better performance for certain configurations and system sizes.

The `omp` style invokes settings associated with the use of the OPENMP package.

The `Nthreads` argument sets the number of OpenMP threads allocated for each MPI task. For example, if your system has nodes with dual quad-core processors, it has a total of 8 cores per node. You could use two MPI tasks per node (e.g. using the `-ppn` option of the `mpirun` command in MPICH or `-npernode` in OpenMPI), and set `Nthreads = 4`. This would use all 8 cores on each node. Note that the product of MPI tasks * threads/task should not exceed the physical number of cores (on a node), otherwise performance will suffer.

Setting `Nthreads = 0` instructs LAMMPS to use whatever value is the default for the given OpenMP environment. This is usually determined via the `OMP_NUM_THREADS` environment variable or the compiler runtime. Note that in most cases the default for OpenMP capable compilers is to use one thread for each available CPU core when `OMP_NUM_THREADS` is not explicitly set, which can lead to poor performance.

Here are examples of how to set the environment variable when launching LAMMPS:

```
env OMP_NUM_THREADS=4 lmp_machine -sf omp -in in.script
env OMP_NUM_THREADS=2 mpirun -np 2 lmp_machine -sf omp -in in.script
mpirun -x OMP_NUM_THREADS=2 -np 2 lmp_machine -sf omp -in in.script
```

or you can set it permanently in your shell’s start-up script. All three of these examples use a total of 4 CPU cores.

Note that different MPI implementations have different ways of passing the `OMP_NUM_THREADS` environment variable to all MPI processes. The second example line above is for MPICH; the third example line with `-x` is for OpenMPI. Check your MPI documentation for additional details.
What combination of threads and MPI tasks gives the best performance is difficult to predict and can depend on many components of your input. Not all features of LAMMPS support OpenMP threading via the OPENMP package and the parallel efficiency can be very different, too.

**Note:** If you build LAMMPS with the GPU, INTEL, and / or OPENMP packages, be aware these packages all allow setting of the Nthreads value via their package commands, but there is only a single global Nthreads value used by OpenMP. Thus if multiple package commands are invoked, you should insure the values are consistent. If they are not, the last one invoked will take precedence, for all packages. Also note that if the `-sf hybrid intel omp command-line switch` is used, it invokes a “package intel” command, followed by a “package omp” command, both with a setting of Nthreads = 0. Likewise for a hybrid suffix for gpu and omp. Note that KOKKOS also supports setting the number of OpenMP threads from the command line using the “-k on” command-line switch. The default for KOKKOS is 1 thread per MPI task, so any other number of threads should be explicitly set using the “-k on” command-line switch (and this setting should be consistent with settings from any other packages used).

Optional keyword/value pairs can also be specified. Each has a default value as listed below.

The neigh keyword specifies whether neighbor list building will be multi-threaded in addition to force calculations. If neigh is set to no then neighbor list calculation is performed only by MPI tasks with no OpenMP threading. If mode is yes (the default), a multi-threaded neighbor list build is used. Using neigh = yes is almost always faster and should produce identical neighbor lists at the expense of using more memory. Specifically, neighbor list pages are allocated for all threads at the same time and each thread works within its own pages.

### 16.93.4 Restrictions

This command cannot be used after the simulation box is defined by a `read_data` or `create_box` command.

The gpu style of this command can only be invoked if LAMMPS was built with the GPU package. See the Build package doc page for more info.

The intel style of this command can only be invoked if LAMMPS was built with the INTEL package. See the Build package page for more info.

The kk style of this command can only be invoked if LAMMPS was built with the KOKKOS package. See the Build package doc page for more info.

The omp style of this command can only be invoked if LAMMPS was built with the OPENMP package. See the Build package doc page for more info.

### 16.93.5 Related commands

`suffix`, `-pk command-line switch`
16.93.6 Default

For the GPU package, the default is Ngpu = 0 and the option defaults are neigh = yes, newton = off, binsize = 0.0, split = 1.0, gpuID = 0 to Ngpu-1, tpa = 1, omp = 0, and platform=-1. These settings are made automatically if the “-sf gpu” command-line switch is used. If it is not used, you must invoke the package gpu command in your input script or via the “-pk gpu” command-line switch.

For the INTEL package, the default is Nphi = 1 and the option defaults are omp = 0, mode = mixed, lrt = no, balance = -1, tpc = 4, tptask = 240. The default ghost option is determined by the pair style being used. This value is output to the screen in the offload report at the end of each run. Note that all of these settings, except “omp” and “mode”, are ignored if LAMMPS was not built with Xeon Phi co-processor support. These settings are made automatically if the “-sf intel” command-line switch is used. If it is not used, you must invoke the package intel command in your input script or via the “-pk intel” command-line switch.

For the KOKKOS package, the option defaults for GPUs are neigh = full, neigh/qeq = full, newton = off, binsize for GPUs = 2x LAMMPS default value, comm = device, neigh/transpose = off, gpu/aware = on. When LAMMPS can safely detect that GPU-aware MPI is not available, the default value of gpu/aware becomes “off”. For CPUs or Xeon Phis, the option defaults are neigh = half, neigh/qeq = half, newton = on, binsize = 0.0, and comm = no. The option neigh/thread = on when there are 16K atoms or less on an MPI rank, otherwise it is “off”. These settings are made automatically by the required “-k on” command-line switch. You can change them by using the package kokkos command in your input script or via the -pk kokkos command-line switch.

For the OMP package, the default is Nthreads = 0 and the option defaults are neigh = yes. These settings are made automatically if the “-sf omp” command-line switch is used. If it is not used, you must invoke the package omp command in your input script or via the “-pk omp” command-line switch.

16.94 pair_coeff command

16.94.1 Syntax

```plaintext
pair_coeff I J args
```

- IJ = atom types (see asterisk form below)
- args = coefficients for one or more pairs of atom types

16.94.2 Examples

```plaintext
pair_coeff 1 2 1.0 1.0 2.5
pair_coeff 2 * 1.0 1.0
pair_coeff 3* 1*2 1.0 1.0 2.5
pair_coeff * * 1.0 1.0
pair_coeff * * nialhjea 1 1 2
pair_coeff * * morse.table ENTRY1
pair_coeff 1 2 lj/cut 1.0 1.0 2.5 (for pair_style hybrid)
```
16.94.3 Description

Specify the pairwise force field coefficients for one or more pairs of atom types. The number and meaning of the coefficients depends on the pair style. Pair coefficients can also be set in the data file read by the read_data command or in a restart file.

I and J can be specified in one of two ways. Explicit numeric values can be used for each, as in the first example above. I <= J is required. LAMMPS sets the coefficients for the symmetric J,I interaction to the same values.

A wildcard asterisk can be used in place of or in conjunction with the I,J arguments to set the coefficients for multiple pairs of atom types. This takes the form “**” or “*n” or “n**” or “m*n”. If N = the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive). Note that only type pairs with I <= J are considered; if asterisks imply type pairs where J < I, they are ignored.

Note that a pair_coeff command can override a previous setting for the same I,J pair. For example, these commands set the coeffs for all I,J pairs, then overwrite the coeffs for just the I,J = 2,3 pair:

```
pair_coeff  * * 1.0 1.0 2.5
pair_coeff  2 3 2.0 1.0 1.12
```

A line in a data file that specifies pair coefficients uses the exact same format as the arguments of the pair_coeff command in an input script, with the exception of the I,J type arguments. In each line of the “Pair Coefs” section of a data file, only a single type I is specified, which sets the coefficients for type I interacting with type I. This is because the section has exactly N lines, where N = the number of atom types. For this reason, the wild-card asterisk should also not be used as part of the I argument. Thus in a data file, the line corresponding to the first example above would be listed as

```
2 1.0 1.0 2.5
```

For many potentials, if coefficients for type pairs with I != J are not set explicitly by a pair_coeff command, the values are inferred from the I,I and J,J settings by mixing rules; see the pair_modify command for a discussion. Details on this option as it pertains to individual potentials are described on the page for the potential.

Many pair styles, typically for many-body potentials, use tabulated potential files as input, when specifying the pair_coeff command. Potential files provided with LAMMPS are in the potentials directory of the distribution. For some potentials, such as EAM, other archives of suitable files can be found on the Web. They can be used with LAMMPS so long as they are in the format LAMMPS expects, as discussed on the individual doc pages. The first line of potential files may contain metadata with upper case tags followed their value. These may be parsed and used by LAMMPS. Currently supported are the “DATE:” tag and the UNITS: tag. For pair styles that have been programmed to support the metadata, the value of the “DATE:” tag is printed to the screen and logfile so that the version of a potential file can be later identified. The UNITS: tag indicates the units setting required for this particular potential file. If the potential file was created for a different set of units, LAMMPS will terminate with an error. If the potential file does not contain the tag, no check will be made and it is the responsibility of the user to determine that the unit style is correct.

In some select cases and for specific combinations of unit styles, LAMMPS is capable of automatically converting potential parameters from a file. In those cases, a warning message signaling that an automatic conversion has happened is printed to the screen.

When a pair_coeff command using a potential file is specified, LAMMPS looks for the potential file in 2 places. First it looks in the location specified. E.g. if the file is specified as “niu3.eam”, it is looked for in the current working directory. If it is specified as “./potentials/niu3.eam”, then it is looked for in the potentials directory, assuming it is a sister directory of the current working directory. If the file is not found, it is then looked for in one of the directories specified by the LAMMPS_POTENTIALS environment variable. Thus if this is set to the potentials directory in the LAMMPS distribution, then you can use those files from anywhere on your system, without copying them into your working directory. Environment variables are set in different ways for different shells. Here are example settings for csh, tcsh:
bash:

```bash
% export LAMMPS_POTENTIALS=/path/to/lammps/potentials
```

Windows:

```bash
% set LAMMPS_POTENTIALS=C:\Path to LAMMS\Potentials
```

The `LAMMPS_POTENTIALS` environment variable may contain paths to multiple folders, if they are separated by “;” on Windows and “:” on all other operating systems, just like the PATH and similar environment variables.

The alphabetic list of pair styles defined in LAMMPS is given on the `pair_style` doc page. They are also listed in more compact form on the `Commands pair` doc page.

Click on the style to display the formula it computes and its coefficients as specified by the associated `pair_coeff` command.

### 16.94.4 Restrictions

This command must come after the simulation box is defined by a `read_data`, `read_restart`, or `create_box` command.

### 16.94.5 Related commands

`pair_style`, `pair_modify`, `read_data`, `read_restart`, `pair_write`

### 16.94.6 Default

none

### 16.95 `pair_modify` command

#### 16.95.1 Syntax

```
pair_modify keyword values ...
```

- one or more keyword/value pairs may be listed
- keyword = `pair` or `shift` or `mix` or `table` or `table/disp` or `tabinner` or `tabinner/disp` or `tail` or `compute` or `nofdotr` or `special` or `compute/tally`
  - `pair` value = sub-style N
  - sub-style = sub-style of `pair hybrid`
    - N = which instance of sub-style (1 to M), only specify if sub-style is used multiple times
  - `mix` value = `geometric` or `arithmetic` or `sixthpower`
  - `shift` value = `yes` or `no`
table value = N
2^N = # of values in table
table/disp value = N
2^N = # of values in table
tabinner value = cutoff
cutoff = inner cutoff at which to begin table (distance units)
tabinner/disp value = cutoff
cutoff = inner cutoff at which to begin table (distance units)
tail value = yes or no
compute value = yes or no
nofdotr value = none
special values = which wt1 wt2 wt3
which = lj/coul or lj or coul
w1,w2,w3 = 1-2, 1-3, 1-4 weights from 0.0 to 1.0 inclusive
compute/tally value = yes or no

16.95.2 Examples

```
pair_modify shift yes mix geometric
pair_modify tail yes
pair_modify table 12
pair_modify pair lj/cut compute no
pair_modify pair tersoff compute/tally no
pair_modify pair lj/cut/coul/long 1 special lj/coul 0.0 0.0 0.0
pair_modify pair lj/cut/coul/long special lj 0.0 0.0 0.5 special coul 0.0 0.0 0.8333333
```

16.95.3 Description

Modify the parameters of the currently defined pair style. If the pair style is hybrid or hybrid/overlay, then the specified parameters are by default modified for all the hybrid sub-styles.

**Note:** The behavior for hybrid pair styles can be changed by using the `pair` keyword, which allows selection of a specific sub-style to apply all remaining keywords to. The `special` and `compute/tally` keywords can only be used in conjunction with the `pair` keyword. See further details about these 3 keywords below.

The `mix` keyword affects pair coefficients for interactions between atoms of type I and J, when I != J and the coefficients are not explicitly set in the input script. Note that coefficients for I = J must be set explicitly, either in the input script via the `pair_coeff` command or in the “Pair Coeffs” or “PairIJ Coeffs” sections of the data file. For some pair styles it is not necessary to specify coefficients when I != J, since a “mixing” rule will create them from the I,I and J,J settings. The `pair_modify mix` value determines what formulas are used to compute the mixed coefficients. In each case, the cutoff distance is mixed the same way as sigma.

Note that not all pair styles support mixing and some mix options are not available for certain pair styles. Also, there are additional restrictions when using `pair style hybrid or hybrid/overlay`. See the page for individual pair styles for those restrictions. Note also that the `pair_coeff` command also can be used to directly set coefficients for a specific I != J pairing, in which case no mixing is performed. If possible, LAMMPS will print an informational message about how many of the mixed pair coefficients were generated and which mixing rule was applied.

- mix geometric

\[
e_{ij} = \sqrt{e_i e_j}
\]

\[
\sigma_{ij} = \sqrt{\sigma_i \sigma_j}
\]
• **mix arithmetic**

\[
\epsilon_{ij} = \sqrt{\epsilon_i \epsilon_j}
\]
\[
\sigma_{ij} = \frac{1}{2} (\sigma_i + \sigma_j)
\]

• **mix sixthpower**

\[
\epsilon_{ij} = \frac{2}{3} \sqrt{\epsilon_i \epsilon_j} \sigma_i^3 \sigma_j^3
\]
\[
\sigma_{ij} = \left( \frac{1}{2} (\sigma_i^6 + \sigma_j^6) \right)^{\frac{1}{6}}
\]

The *shift* keyword determines whether a Lennard-Jones potential is shifted at its cutoff to 0.0. If so, this adds an energy term to each pairwise interaction which will be included in the thermodynamic output, but does not affect pair forces or atom trajectories. See the doc page for individual pair styles to see which ones support this option.

The *table* and *table/disp* keywords apply to pair styles with a long-range Coulombic term or long-range dispersion term respectively; see the page for individual styles to see which potentials support these options. If \( N \) is non-zero, a table of length \( 2^N \) is pre-computed for forces and energies, which can shrink their computational cost by up to a factor of 2. The table is indexed via a bit-mapping technique ([Wolff](#)) and a linear interpolation is performed between adjacent table values. In our experiments with different table styles (lookup, linear, spline), this method typically gave the best performance in terms of speed and accuracy.

The choice of table length is a tradeoff in accuracy versus speed. A larger \( N \) yields more accurate force computations, but requires more memory which can slow down the computation due to cache misses. A reasonable value of \( N \) is between 8 and 16. The default value of 12 (table of length 4096) gives approximately the same accuracy as the no-table (\( N = 0 \)) option. For \( N = 0 \), forces and energies are computed directly, using a polynomial fit for the needed erfc() function evaluation, which is what earlier versions of LAMMPS did. Values greater than 16 typically slow down the simulation and will not improve accuracy; values from 1 to 8 give unreliable results.

The *tabinner* and *tabinner/disp* keywords set an inner cutoff above which the pairwise computation is done by table lookup (if tables are invoked), for the corresponding Coulombic and dispersion tables discussed with the *table* and *table/disp* keywords. The smaller the cutoff is set, the less accurate the table becomes (for a given number of table values), which can require use of larger tables. The default cutoff value is \( \sqrt{2.0} \) distance units which means nearly all pairwise interactions are computed via table lookup for simulations with “real” units, but some close pairs may be computed directly (non-table) for simulations with “lj” units.

When the *tail* keyword is set to *yes*, certain pair styles will add a long-range VanderWaals tail “correction” to the energy and pressure. These corrections are bookkeeping terms which do not affect dynamics, unless a constant-pressure simulation is being performed. See the page for individual styles to see which support this option. These corrections are included in the calculation and printing of thermodynamic quantities (see the *thermo_style* command). Their effect will also be included in constant NPT or NPH simulations where the pressure influences the simulation box dimensions (e.g. the *fix npt* and *fix nph* commands). The formulas used for the long-range corrections come from equation 5 of ([Sun](#)).

**Note:** The tail correction terms are computed at the beginning of each run, using the current atom counts of each atom type. If atoms are deleted (or lost) or created during a simulation, e.g. via the *fix gmc* command, the correction factors are not re-computed. If you expect the counts to change dramatically, you can break a run into a series of shorter runs so that the correction factors are re-computed more frequently.

Several additional assumptions are inherent in using tail corrections, including the following:

- The simulated system is a 3d bulk homogeneous liquid. This option should not be used for systems that are non-liquid, 2d, have a slab geometry (only 2d periodic), or inhomogeneous.
• G(r), the radial distribution function (rdf), is unity beyond the cutoff, so a fairly large cutoff should be used (i.e. 2.5 sigma for an LJ fluid), and it is probably a good idea to verify this assumption by checking the rdf. The rdf is not exactly unity beyond the cutoff for each pair of interaction types, so the tail correction is necessarily an approximation.

The tail corrections are computed at the beginning of each simulation run. If the number of atoms changes during the run, e.g. due to atoms leaving the simulation domain, or use of the fix gcmc command, then the corrections are not updated to reflect the changed atom count. If this is a large effect in your simulation, you should break the long run into several short runs, so that the correction factors are re-computed multiple times.

• Thermophysical properties obtained from calculations with this option enabled will not be thermodynamically consistent with the truncated force-field that was used. In other words, atoms do not feel any LJ pair interactions beyond the cutoff, but the energy and pressure reported by the simulation include an estimated contribution from those interactions.

The compute keyword allows pairwise computations to be turned off, even though a pair_style is defined. This is not useful for running a real simulation, but can be useful for debugging purposes or for performing a rerun simulation, when you only wish to compute partial forces that do not include the pairwise contribution.

Two examples are as follows. First, this option allows you to perform a simulation with pair_style hybrid with only a subset of the hybrid sub-styles enabled. Second, this option allows you to perform a simulation with only long-range interactions but no short-range pairwise interactions. Doing this by simply not defining a pair style will not work, because the kspace_style command requires a Kspace-compatible pair style be defined.

The nolatix keyword allows to disable an optimization that computes the global stress tensor from the total forces and atom positions rather than from summing forces between individual pairs of atoms.

The pair keyword can only be used with the hybrid and hybrid/overlay pair styles. If used, it must appear first in the list of keywords.

Its meaning is that all the following parameters will only be modified for the specified sub-style. If the sub-style is defined multiple times, then an additional numeric argument N must also be specified, which is a number from 1 to M where M is the number of times the sub-style was listed in the pair_style hybrid command. The extra number indicates which instance of the sub-style the remaining keywords will be applied to.

The special and compute/tally keywords can only be used in conjunction with the pair keyword and they must directly follow it. I.e. any other keyword, must appear after pair, special, and compute/tally.

The special keyword overrides the global special_bonds 1-2, 1-3, 1-4 exclusion settings (weights) for the sub-style selected by the pair keyword.

Similar to the special_bonds command, it takes 4 arguments. The which argument can be lj to change only the non-Coulomb weights (e.g. Lennard-Jones or Buckingham), coul to change only the Coulombic settings, or lj/coul to change both to the same values. The wt1, wt2, wt3 values are numeric weights from 0.0 to 1.0 inclusive, for the 1-2, 1-3, and 1-4 bond topology neighbors, respectively. The special keyword can be used multiple times, e.g. to set the lj and coul settings to different values.

Note: The special keyword is not compatible with pair styles from the GPU or the INTEL package and attempting to use it will cause an error.

Note: Weights of exactly 0.0 or 1.0 in the special_bonds command have implications on the neighbor list construction, which means that they cannot be overridden by using the special keyword. One workaround for this restriction is to use the special_bonds command with weights like 1.0e-10 or 0.999999999 instead of 0.0 or 1.0, respectively, which enables to reset each them to any value between 0.0 and 1.0 inclusively. Otherwise you can set all global weights to an
arbitrary number between 0.0 or 1.0, like 0.5, and then you have to override all special settings for all sub-styles which use the 1-2, 1-3, and 1-4 exclusion weights in their force/energy computation.

The compute/tally keyword disables or enables registering compute */tally computes for the sub-style specified by the pair keyword. Use no to disable, or yes to enable.

Note: The “pair_modify pair compute/tally” command must be issued before the corresponding compute style is defined.

16.95.4 Restrictions

You cannot use shift yes with tail yes, since those are conflicting options. You cannot use tail yes with 2d simulations. You cannot use special with pair styles from the GPU or INTEL package.

16.95.5 Related commands

pair_style, pair_style hybrid, pair_coeff, thermo_style, compute */tally

16.95.6 Default

The option defaults are mix = geometric, shift = no, table = 12, tabinner = sqrt(2.0), tail = no, and compute = yes.

Note that some pair styles perform mixing, but only a certain style of mixing. See the doc pages for individual pair styles for details.

16.96 pair_style command

16.96.1 Syntax

pair_style style args

• style = one of the styles from the list below
• args = arguments used by a particular style
16.96.2 Examples

```plaintext
pair_style lj/cut 2.5
pair_style eam/alloy
pair_style hybrid lj/charmm/coul/long 10.0 eam
pair_style table linear 1000
pair_style none
```

16.96.3 Description

Set the formula(s) LAMMPS uses to compute pairwise interactions. In LAMMPS, pair potentials are defined between pairs of atoms that are within a cutoff distance and the set of active interactions typically changes over time. See the `bond_style` command to define potentials between pairs of bonded atoms, which typically remain in place for the duration of a simulation.

In LAMMPS, pairwise force fields encompass a variety of interactions, some of which include many-body effects, e.g. EAM, Stillinger-Weber, Tersoff, REBO potentials. They are still classified as “pairwise” potentials because the set of interacting atoms changes with time (unlike molecular bonds) and thus a neighbor list is used to find nearby interacting atoms.

Hybrid models where specified pairs of atom types interact via different pair potentials can be setup using the `hybrid` pair style.

The coefficients associated with a pair style are typically set for each pair of atom types, and are specified by the `pair_coeff` command or read from a file by the `read_data` or `read_restart` commands.

The `pair_modify` command sets options for mixing of type I-J interaction coefficients and adding energy offsets or tail corrections to Lennard-Jones potentials. Details on these options as they pertain to individual potentials are described on the doc page for the potential. Likewise, info on whether the potential information is stored in a restart file is listed on the potential doc page.

In the formulas listed for each pair style, $E$ is the energy of a pairwise interaction between two atoms separated by a distance $r$. The force between the atoms is the negative derivative of this expression.

If the `pair_style` command has a cutoff argument, it sets global cutoffs for all pairs of atom types. The distance(s) can be smaller or larger than the dimensions of the simulation box.

In many cases, the global cutoff value can be overridden for a specific pair of atom types by the `pair_coeff` command.

If a new `pair_style` command is specified with a new style, all previous `pair_coeff` and `pair_modify` command settings are erased; those commands must be re-specified if necessary.

If a new `pair_style` command is specified with the same style, then only the global settings in that command are reset. Any previous doc:`pair_coeff <pair_coeff>` and `pair_modify` command settings are preserved. The only exception is that if the global cutoff in the `pair_style` command is changed, it will override the corresponding cutoff in any of the previous doc:`pair_modify <pair_coeff>` commands.

Two pair styles which do not follow this rule are the `pair_style table` and `hybrid` commands. A new `pair_style` command for these styles will wipe out all previously specified doc:`pair_coeff <pair_coeff>` and `pair_modify` settings, including for the sub-styles of the `hybrid` command.

Here is an alphabetic list of pair styles defined in LAMMPS. They are also listed in more compact form on the Commands pair doc page.

Click on the style to display the formula it computes, any additional arguments specified in the `pair_style` command, and coefficients specified by the associated `pair_coeff` command.
There are also additional accelerated pair styles included in the LAMMPS distribution for faster performance on CPUs, GPUs, and KNLs. The individual style names on the Commands pair doc page are followed by one or more of (g,i,k,o,t) to indicate which accelerated styles exist.

- **none** - turn off pairwise interactions
- **hybrid** - multiple styles of pairwise interactions
- **hybrid/overlay** - multiple styles of superposed pairwise interactions
- **hybrid/scaled** - multiple styles of scaled superposed pairwise interactions
- **zero** - neighbor list but no interactions
- **adp** - angular dependent potential (ADP) of Mishin
- **agni** - AGNI machine-learning potential
- **airebo** - AIREBO potential of Stuart
- **airebo/morse** - AIREBO with Morse instead of LJ
- **atm** - Axilrod-Teller-Muto potential
- **awpmd/cut** - Antisymmetrized Wave Packet MD potential for atoms and electrons
- **beck** - Beck potential
- **body/nparticle** - interactions between body particles
- **body/rounded/polygon** - granular-style 2d polygon potential
- **body/rounded/polyhedron** - granular-style 3d polyhedron potential
- **bop** - BOP potential of Pettifor
- **born** - Born-Mayer-Huggins potential
- **born/coul/dsf** - Born with damped-shifted-force model
- **born/coul/dsf/cs** - Born with damped-shifted-force and core/shell model
- **born/coul/long** - Born with long-range Coulomb
- **born/coul/long/cs** - Born with long-range Coulomb and core/shell
- **born/coul/msm** - Born with long-range MSM Coulomb
- **born/coul/wolf** - Born with Wolf potential for Coulomb
- **born/coul/wolf/cs** - Born with Wolf potential for Coulomb and core/shell
- **bpm/spring** - repulsive harmonic force with damping
- **brownian** - Brownian potential for Fast Lubrication Dynamics
- **brownian/poly** - Brownian potential for Fast Lubrication Dynamics with polydispersity
- **buck** - Buckingham potential
- **buck/coul/cut** - Buckingham with cutoff Coulomb
- **buck/coul/long** - Buckingham with long-range Coulomb
- **buck/coul/long/cs** - Buckingham with long-range Coulomb and core/shell
- **buck/coul/msm** - Buckingham with long-range MSM Coulomb
- **buck/long/coul/long** - long-range Buckingham with long-range Coulomb
- **buck/mdf** - Buckingham with a taper function
• *buck6d/coul/gauss/dsf* - dispersion-damped Buckingham with damped-shift-force model
• *buck6d/coul/gauss/long* - dispersion-damped Buckingham with long-range Coulomb
• *colloid* - integrated colloidal potential
• *comb* - charge-optimized many-body (COMB) potential
• *comb3* - charge-optimized many-body (COMB3) potential
• *cosine/squared* - Cooke-Kremer-Deserno membrane model potential
• *coul/cut* - cutoff Coulomb potential
• *coul/cut/dielectric* -
• *coul/cut/global* - cutoff Coulomb potential
• *coul/cut/soft* - Coulomb potential with a soft core
• *coul/debye* - cutoff Coulomb potential with Debye screening
• *coul/diel* - Coulomb potential with dielectric permittivity
• *coul/dsf* - Coulomb with damped-shifted-force model
• *coul/exclude* - subtract Coulomb potential for excluded pairs
• *coul/long* - long-range Coulomb potential
• *coul/long/cs* - long-range Coulomb potential and core/shell
• *coul/long/dielectric* -
• *coul/long/soft* - long-range Coulomb potential with a soft core
• *coul/msm* - long-range MSM Coulomb
• *coul/slater/cut* - smeared out Coulomb
• *coul/slater/long* - long-range smeared out Coulomb
• *coul/shield* - Coulomb for boron nitride for use with *ilp/graphene/hbn* potential
• *coul/streitz* - Coulomb via Streitz/Mintmire Slater orbitals
• *coul/tt* - damped charge-dipole Coulomb for Drude dipoles
• *coul/wolf* - Coulomb via Wolf potential
• *coul/wolf/cs* - Coulomb via Wolf potential with core/shell adjustments
• *dpd* - dissipative particle dynamics (DPD)
• *dpd/ext* - generalized force field for DPD
• *dpd/ext/tstat* - pairwise DPD thermostatting with generalized force field
• *dpd/fdt* - DPD for constant temperature and pressure
• *dpd/fdt/energy* - DPD for constant energy and enthalpy
• *dpd/tstat* - pairwise DPD thermostatting
• *dsmc* - Direct Simulation Monte Carlo (DSMC)
• *e3b* - Explicit-three body (E3B) water model
• *drip* - Dihedral-angle-corrected registry-dependent interlayer potential (DRIP)
• *eam* - embedded atom method (EAM)
- **eam/alloy** - alloy EAM
- **eam/cd** - concentration-dependent EAM
- **eam/cd/old** - older two-site model for concentration-dependent EAM
- **eam/he** - Finnis-Sinclair EAM modified for Helium in metals
- **edip** - three-body EDIP potential
- **edip/multi** - multi-element EDIP potential
- **edpd** - eDPD particle interactions
- **eff/cut** - electron force field with a cutoff
- **eim** - embedded ion method (EIM)
- **exp6/rx** - reactive DPD potential
- **extep** - extended Tersoff potential
- **gauss** - Gaussian potential
- **gauss/cut** - generalized Gaussian potential
- **gayberne** - Gay-Berne ellipsoidal potential
- **granular** - Generalized granular potential
- **gran/hertz/history** - granular potential with Hertzian interactions
- **gran/hooke** - granular potential with history effects
- **gran/hooke/history** - granular potential without history effects
- **gw** - Gao-Weber potential
- **gw/zbl** - Gao-Weber potential with a repulsive ZBL core
- **harmonic/cut** - repulsive-only harmonic potential
- **hbond/dreiding/lj** - DREIDING hydrogen bonding LJ potential
- **hbond/dreiding/morse** - DREIDING hydrogen bonding Morse potential
- **hdnnp** - High-dimensional neural network potential
- **ilp/graphene/hbn** - registry-dependent interlayer potential (ILP)
- **ilp/tmd** - interlayer potential (ILP) potential for transition metal dichalcogenides (TMD)
- **kim** - interface to potentials provided by KIM project
- **kolmogorov/crespi/full** - Kolmogorov-Crespi (KC) potential with no simplifications
- **kolmogorov/crespi/z** - Kolmogorov-Crespi (KC) potential with normals along z-axis
- **lcbop** - long-range bond-order potential (LCBOP)
- **lebedeva/z** - Lebedeva interlayer potential for graphene with normals along z-axis
- **lennard/mdf** - LJ potential in A/B form with a taper function
- **line/lj** - LJ potential between line segments
- **list** - potential between pairs of atoms explicitly listed in an input file
- **lj/charmm/coul/charmm** - CHARMM potential with cutoff Coulomb
• \texttt{lj/charmm/coul/charmm/implicit} - CHARMM for implicit solvent
• \texttt{lj/charmm/coul/long} - CHARMM with long-range Coulomb
• \texttt{lj/charmm/coul/long/soft} - CHARMM with long-range Coulomb and a soft core
• \texttt{lj/charmm/coul/msm} - CHARMM with long-range MSM Coulomb
• \texttt{lj/charmmfsw/coul/charmmfsh} - CHARMM with force switching and shifting
• \texttt{lj/charmmfsw/coul/long} - CHARMM with force switching and long-range Coulomb
• \texttt{lj/class2} - COMPASS (class 2) force field without Coulomb
• \texttt{lj/class2/coul/cut} - COMPASS with cutoff Coulomb
• \texttt{lj/class2/coul/cut/soft} - COMPASS with cutoff Coulomb with a soft core
• \texttt{lj/class2/coul/long} - COMPASS with long-range Coulomb
• \texttt{lj/class2/coul/long/cs} - COMPASS with long-range Coulomb with core/shell adjustments
• \texttt{lj/class2/coul/long/soft} - COMPASS with long-range Coulomb with a soft core
• \texttt{lj/class2/soft} - COMPASS (class 2) force field with no Coulomb with a soft core
• \texttt{lj/cubic} - LJ with cubic after inflection point
• \texttt{lj/cut} - cutoff Lennard-Jones potential without Coulomb
• \texttt{lj/cut/coul/cut} - LJ with cutoff Coulomb
• \texttt{lj/cut/coul/cut/dielectric} -
• \texttt{lj/cut/coul/cut/soft} - LJ with cutoff Coulomb with a soft core
• \texttt{lj/cut/coul/debye} - LJ with Debye screening added to Coulomb
• \texttt{lj/cut/coul/debye/dielectric} -
• \texttt{lj/cut/coul/dsf} - LJ with Coulomb via damped shifted forces
• \texttt{lj/cut/coul/long} - LJ with long-range Coulomb
• \texttt{lj/cut/coul/long/cs} - LJ with long-range Coulomb with core/shell adjustments
• \texttt{lj/cut/coul/long/dielectric} -
• \texttt{lj/cut/coul/long/soft} - LJ with long-range Coulomb with a soft core
• \texttt{lj/cut/coul/msm} - LJ with long-range MSM Coulomb
• \texttt{lj/cut/coul/msm/dielectric} -
• \texttt{lj/cut/coul/wolf} - LJ with Coulomb via Wolf potential
• \texttt{lj/cut/dipole/cut} - point dipoles with cutoff
• \texttt{lj/cut/dipole/long} - point dipoles with long-range Ewald
• \texttt{lj/cut/soft} - LJ with a soft core
• \texttt{lj/cut/thole/long} - LJ with Coulomb with thole damping
• \texttt{lj/cut/tip4p/cut} - LJ with cutoff Coulomb for TIP4P water
• \texttt{lj/cut/tip4p/long} - LJ with long-range Coulomb for TIP4P water
• \texttt{lj/cut/tip4p/long/soft} - LJ with cutoff Coulomb for TIP4P water with a soft core
• \texttt{lj/expand} - Lennard-Jones for variable size particles
• **lj/expand/coul/long** - Lennard-Jones for variable size particles with long-range Coulomb
• **lj/gromacs** - GROMACS-style Lennard-Jones potential
• **lj/gromacs/coul/gromacs** - GROMACS-style LJ and Coulomb potential
• **lj/long/coul/long** - long-range LJ and long-range Coulomb
• **lj/long/coul/dielectric** -
• **lj/long/dipole/long** - long-range LJ and long-range point dipoles
• **lj/long/tip4p/long** - long-range LJ and long-range Coulomb for TIP4P water
• **lj/mdf** - LJ potential with a taper function
• **lj/relres** - LJ using multiscale Relative Resolution (RelRes) methodology (*Chaimovich*).
• **lj/sdk** - LJ for SDK coarse-graining
• **lj/sdk/coul/long** - LJ for SDK coarse-graining with long-range Coulomb
• **lj/sdk/coul/msm** - LJ for SDK coarse-graining with long-range Coulomb via MSM
• **lj/sf/dipole/sf** - LJ with dipole interaction with shifted forces
• **lj/smooth** - smoothed Lennard-Jones potential
• **lj/smooth/linear** - linear smoothed LJ potential
• **lj/switch3/coulgauss/long** - smoothed LJ vdW potential with Gaussian electrostatics
• **lj96/cut** - Lennard-Jones 9/6 potential
• **local/density** - generalized basic local density potential
• **lubricate** - hydrodynamic lubrication forces
• **lubricate/poly** - hydrodynamic lubrication forces with polydispersity
• **lubricateU** - hydrodynamic lubrication forces for Fast Lubrication Dynamics
• **lubricateU/poly** - hydrodynamic lubrication forces for Fast Lubrication with polydispersity
• **mdpd** - mDPD particle interactions
• **mdpd/rhosum** - mDPD particle interactions for mass density
• **meam** - modified embedded atom method (MEAM) in C
• **meam/spline** - splined version of MEAM
• **meam/sw/spline** - splined version of MEAM with a Stillinger-Weber term
• **mesocnt** - mesoscale model for (carbon) nanotubes
• **mgpt** - simplified model generalized pseudopotential theory (MGPT) potential
• **mesont/tpm** - nanotubes mesoscopic force field
• **mie/cut** - Mie potential
• **mm3/switch3/coulgauss/long** - smoothed MM3 vdW potential with Gaussian electrostatics
• **momb** - Many-Body Metal-Organic (MOMB) force field
• **morse** - Morse potential
• **morse/smooth/linear** - linear smoothed Morse potential
• **morse/soft** - Morse potential with a soft core
- **multi/lucy** - DPD potential with density-dependent force
- **multi/lucy/rx** - reactive DPD potential with density-dependent force
- **nb3b/harmonic** - non-bonded 3-body harmonic potential
- **nm/cut** - N-M potential
- **nm/cut/coul/cut** - N-M potential with cutoff Coulomb
- **nm/cut/coul/long** - N-M potential with long-range Coulomb
- **nm/cut/split** - Split 12-6 Lennard-Jones and N-M potential
- **oxdna/coaxstk** -
- **oxdna/excv** -
- **oxdna/hbond** -
- **oxdna/stk** -

• **threebody/table** - generic tabulated three-body potential
• **tip4p/cut** - Coulomb for TIP4P water w/out LJ
• **tip4p/long** - long-range Coulomb for TIP4P water w/out LJ
• **tip4p/long/soft** -
• **tracker** - monitor information about pairwise interactions
• **tri/lj** - LJ potential between triangles
• **ufm** -
• **vashishta** - Vashishta 2-body and 3-body potential
• **vashishta/table** -
• **wf/cut** - Wang-Frenkel Potential for short-ranged interactions
• **yukawa** - Yukawa potential
• **yukawa/colloid** - screened Yukawa potential for finite-size particles
• **zbl** - Ziegler-Biersack-Littmark potential

16.96.4 Restrictions

This command must be used before any coefficients are set by the **pair_coeff**, **read_data**, or **read_restart** commands. Some pair styles are part of specific packages. They are only enabled if LAMMPS was built with that package. See the **Build package** page for more info. The doc pages for individual pair potentials tell if it is part of a package.

16.96.5 Related commands

**pair_coeff**, **read_data**, **pair_modify**, **kspace_style**, **dielectric**, **pair_write**

16.96.6 Default

```
pair_style none
```

16.97 pair_write command

16.97.1 Syntax

```
pair_write itype jtype N style inner outer file keyword Qi Qj
```

- **itype, jtype** = 2 atom types
- **N** = # of values
• style = r or rsq or bitmap
• inner, outer = inner and outer cutoff (distance units)
• file = name of file to write values to
• keyword = section name in file for this set of tabulated values
• Qi, Qj = 2 atom charges (charge units) (optional)

16.97.2 Examples

<table>
<thead>
<tr>
<th>Command</th>
<th>Arguments</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pair_write</td>
<td>1 3 500 r 1.0 10.0 table.txt LJ</td>
<td>Write energy and force values for LJ potential</td>
</tr>
<tr>
<td>pair_write</td>
<td>1 1 1000 rsq 2.0 8.0 table.txt Yukawa_1_1 -0.5 0.5</td>
<td>Write energy and force values for Yukawa potential</td>
</tr>
</tbody>
</table>

16.97.3 Description

Write energy and force values to a file as a function of distance for the currently defined pair potential. This is useful for plotting the potential function or otherwise debugging its values. If the file already exists, the table of values is appended to the end of the file to allow multiple tables of energy and force to be included in one file. In case a new file is created, the first line will be a comment containing a “DATE:” and “UNITS:” tag with the current date and the current units setting as argument. For subsequent invocations of the pair_write command, the current units setting is compared against the entry in the file, if present, and pair_write will refuse to add a table if the units are not the same.

The energy and force values are computed at distances from inner to outer for 2 interacting atoms of type itype and jtype, using the appropriate pair_coeff coefficients. If the style is r, then N distances are used, evenly spaced in r; if the style is rsq, N distances are used, evenly spaced in r^2.

For example, for N = 7, style = r, inner = 1.0, and outer = 4.0, values are computed at r = 1.0, 1.5, 2.0, 2.5, 3.0, 3.5, 4.0.

If the style is bitmap, then 2^N values are written to the file in a format and order consistent with how they are read in by the pair_coeff command for pair style table. For reasonable accuracy in a bitmapped table, choose N >= 12, an inner value that is smaller than the distance of closest approach of 2 atoms, and an outer value <= cutoff of the potential.

If the pair potential is computed between charged atoms, the charges of the pair of interacting atoms can optionally be specified. If not specified, values of Qi = Qj = 1.0 are used.

The file is written in the format used as input for the pair_style table option with keyword as the section name. Each line written to the file lists an index number (1-N), a distance (in distance units), an energy (in energy units), and a force (in force units).

16.97.4 Restrictions

All force field coefficients for pair and other kinds of interactions must be set before this command can be invoked.

Due to how the pairwise force is computed, an inner value > 0.0 must be specified even if the potential has a finite value at r = 0.0.

The pair_write command can only be used for pairwise additive interactions for which a Pair::single() function can be and has been implemented. This excludes for example manybody potentials or TIP4P coulomb styles.

16.97.6 Default

none

16.98 partition command

16.98.1 Syntax

partition style N command ...

- style = yes or no
- N = partition number (see asterisk form below)
- command = any LAMMPS command

16.98.2 Examples

partition yes 1 processors 4 10 6
partition no 5 print "Active partition"
partition yes *5 fix all nve
partition yes 6* fix all nvt temp 1.0 1.0 0.1

16.98.3 Description

This command invokes the specified command on a subset of the partitions of processors you have defined via the
-partition command-line switch.

Normally, every input script command in your script is invoked by every partition. This behavior can be modified by
defining world- or universe-style variables that have different values for each partition. This mechanism can be used
to cause your script to jump to different input script files on different partitions, if such a variable is used in a jump
command.

The “partition” command is another mechanism for having as input script operate differently on different partitions. It
is basically a prefix on any LAMMPS command. The command will only be invoked on the partition(s) specified by
the style and N arguments.

If the style is yes, the command will be invoked on any partition which matches the N argument. If the style is no the
command will be invoked on all the partitions which do not match the Np argument.

Partitions are numbered from 1 to Np, where Np is the number of partitions specified by the -partition command-line
switch.

N can be specified in one of two ways. An explicit numeric value can be used, as in the first example above. Or a
wild-card asterisk can be used to span a range of partition numbers. This takes the form “*” or “*n” or “n*” or “m*n”.
An asterisk with no numeric values means all partitions from 1 to Np. A leading asterisk means all partitions from 1 to
n (inclusive). A trailing asterisk means all partitions from n to Np (inclusive). A middle asterisk means all partitions
from m to n (inclusive).
This command can be useful for the “run_style verlet/split” command which imposed requirements on how the processors command lays out a 3d grid of processors in each of 2 partitions.

16.98.4 Restrictions

none

16.98.5 Related commands

run_style verlet/split

16.98.6 Default

none

16.99 plugin command

16.99.1 Syntax

`plugin command args`

• command = load or unload or list or clear

• args = list of arguments for a particular plugin command

  load file = load plugin(s) from shared object in file
  unload style name = unload plugin name of style style
  style = pair or bond or angle or dihedral or improper or kspace or compute or...
  fix or region or command
  list = print a list of currently loaded plugins
  clear = unload all currently loaded plugins

16.99.2 Examples

```
plugin load morse2plugin.so
plugin unload pair morse2/omp
plugin unload command hello
plugin list
plugin clear
```
16.99.3 Description

The plugin command allows to load (and unload) additional styles and commands into a LAMMPS binary from so-called dynamic shared object (DSO) files. This enables to add new functionality to an existing LAMMPS binary without having to recompile and link the entire executable.

The load command will load and initialize all plugins contained in the plugin DSO with the given filename. A message with information the plugin style and name and more will be printed. Individual DSO files may contain multiple plugins. More details about how to write and compile the plugin DSO is given in programmer’s guide part of the manual under Writing plugins.

The unload command will remove the given style or the given name from the list of available styles. If the plugin style is currently in use, that style instance will be deleted.

The list command will print a list of the loaded plugins and their styles and names.

The clear command will unload all currently loaded plugins.

Automatic loading of plugins

When the environment variable LAMMPS_PLUGIN_PATH is set, then LAMMPS will search the directory (or directories) listed in this path for files with names that end in plugin.so (e.g. helloplugin.so) and will try to load the contained plugins automatically at start-up.

16.99.4 Restrictions

The plugin command is part of the PLUGIN package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

If plugins access functions or classes from a package, LAMMPS must have been compiled with that package included.

Plugins are dependent on the LAMMPS binary interface (ABI) and particularly the MPI library used. So they are not guaranteed to work when the plugin was compiled with a different MPI library or different compilation settings or a different LAMMPS version. There are no checks, so if there is a mismatch the plugin object will either not load or data corruption and crashes may happen.

16.100  prd command

16.100.1 Syntax

```
prd N t_event n_dephase t_dephase t_correlate compute-ID seed keyword value ...
```

- **N** = # of timesteps to run (not including dephasing/quenching)
- **t_event** = timestep interval between event checks
- **n_dephase** = number of velocity randomizations to perform in each dephase run
- **t_dephase** = number of timesteps to run dynamics after each velocity randomization during dephase
- **t_correlate** = number of timesteps within which 2 consecutive events are considered to be correlated
- **compute-ID** = ID of the compute used for event detection
- **random_seed** = random # seed (positive integer)
- zero or more keyword/value pairs may be appended
- **keyword** = **min** or **temp** or **vel**
  - **min values** = etol ftol maxiter maxeval
    - **etol** = stopping tolerance for energy, used in quenching
    - **ftol** = stopping tolerance for force, used in quenching
    - **maxiter** = max iterations of minimize, used in quenching
    - **maxeval** = max number of force/energy evaluations, used in quenching
  - **temp value** = Tdephase
    - **Tdephase** = target temperature for velocity randomization, used in dephasing
  - **vel values** = loop dist
    - **loop** = **all** or **local** or **geom**, used in dephasing
    - **dist** = **uniform** or **gaussian**, used in dephasing
  - **time value** = steps or clock
    - **steps** = simulation runs for N timesteps on each replica (default)
    - **clock** = simulation runs for N timesteps across all replicas

16.100.2 Examples

```
prd 5000 100 10 10 100 1 54982
prd 5000 100 10 10 100 1 54982 min 0.1 0.1 100 200
```

16.100.3 Description

Run a parallel replica dynamics (PRD) simulation using multiple replicas of a system. One or more replicas can be used. The total number of steps \( N \) to run can be interpreted in one of two ways; see discussion of the **time** keyword below.

PRD is described in (Voter1998) by Art Voter. Similar to global or local hyperdynamics (HD), PRD is a method for performing accelerated dynamics that is suitable for infrequent-event systems that obey first-order kinetics. A good overview of accelerated dynamics methods (AMD) for such systems is given in this review paper (Voter2002) from Art's group. To quote from the paper: “The dynamical evolution is characterized by vibrational excursions within a potential basin, punctuated by occasional transitions between basins. The transition probability is characterized by \( p(t) = k\exp(-kt) \) where \( k \) is the rate constant.”
Both PRD and HD produce a time-accurate trajectory that effectively extends the timescale over which a system can be simulated, but they do it differently. PRD creates \( N_r \) replicas of the system and runs dynamics on each independently with a normal unbiased potential until an event occurs in one of the replicas. The time between events is reduced by a factor of \( N_r \) replicas. HD uses a single replica of the system and accelerates time by biasing the interaction potential in a manner such that each timestep is effectively longer. For both methods, per CPU second, more physical time elapses and more events occur. See the \textit{hyper} page for more info about HD.

In PRD, each replica runs on a partition of one or more processors. Processor partitions are defined at run-time using the \textit{-partition command-line switch}. Note that if you have MPI installed, you can run a multi-replica simulation with more replicas (partitions) than you have physical processors, e.g., you can run a 10-replica simulation on one or two processors. However, for PRD, this makes little sense, since running a replica on virtual instead of physical processors offers no effective parallel speed-up in searching for infrequent events. See the \textit{How to replica} doc page for further discussion.

When a PRD simulation is performed, it is assumed that each replica is running the same model, though LAMMPS does not check for this. I.e. the simulation domain, the number of atoms, the interaction potentials, etc should be the same for every replica.

A PRD run has several stages, which are repeated each time an “event” occurs in one of the replicas, as explained below. The logic for a PRD run is as follows:

```plaintext
while (time remains):
    dephase for \( n_{dephase} \times t_{dephase} \) steps
    until (event occurs on some replica):
        run dynamics for \( t_{event} \) steps
        quench
        check for uncorrelated event on any replica
        until (no correlated event occurs):
            run dynamics for \( t_{correlate} \) steps
            quench
            check for correlated event on this replica
    event replica shares state with all replicas
```

Before this loop begins, the state of the system on replica 0 is shared with all replicas, so that all replicas begin from the same initial state. The first potential energy basin is identified by quenching (an energy minimization, see below) the initial state and storing the resulting coordinates for reference.

In the first stage, dephasing is performed by each replica independently to eliminate correlations between replicas. This is done by choosing a random set of velocities, based on the \textit{random_seed} that is specified, and running \( t_{dephase} \) timesteps of dynamics. This is repeated \( n_{dephase} \) times. At each of the \( n_{dephase} \) stages, if an event occurs during the \( t_{dephase} \) steps of dynamics for a particular replica, the replica repeats the stage until no event occurs.

If the \textit{temp} keyword is not specified, the target temperature for velocity randomization for each replica is the current temperature of that replica. Otherwise, it is the specified \( T_{dephase} \) temperature. The style of velocity randomization is controlled using the keyword \textit{vel} with arguments that have the same meaning as their counterparts in the \textit{velocity} command.

In the second stage, each replica runs dynamics continuously, stopping every \( t_{event} \) steps to check if a transition event has occurred. This check is performed by quenching the system and comparing the resulting atom coordinates to the coordinates from the previous basin. The first time through the PRD loop, the “previous basin” is the set of quenched coordinates from the initial state of the system.

A quench is an energy minimization and is performed by whichever algorithm has been defined by the \textit{min_style} command. Minimization parameters may be set via the \textit{min_modify} command and by the \textit{min} keyword of the PRD command. The latter are the settings that would be used with the \textit{minimize} command. Note that typically, you do not need to perform a highly-converged minimization to detect a transition event, though you may need to in order to prevent a set of atoms in the system from relaxing to a saddle point.

The event check is performed by a compute with the specified \textit{compute-ID}. Currently there is only one compute that works with the PRD command, which is the \textit{compute event/displace} command. Other event-checking computes may
be added. **Compute event/displace** checks whether any atom in the compute group has moved further than a specified threshold distance. If so, an “event” has occurred.

In the third stage, the replica on which the event occurred (event replica) continues to run dynamics to search for correlated events. This is done by running dynamics for \( t_{\text{correlate}} \) steps, quenching every \( t_{\text{event}} \) steps, and checking if another event has occurred.

The first time no correlated event occurs, the final state of the event replica is shared with all replicas, the new basin reference coordinates are updated with the quenched state, and the outer loop begins again. While the replica event is searching for correlated events, all the other replicas also run dynamics and event checking with the same schedule, but the final states are always overwritten by the state of the event replica.

The outer loop of the pseudo-code above continues until \( N \) steps of dynamics have been performed. Note that \( N \) only includes the dynamics of stages 2 and 3, not the steps taken during dephasing or the minimization iterations of quenching. The specified \( N \) is interpreted in one of two ways, depending on the `time` keyword. If the `time` value is `steps`, which is the default, then each replica runs for \( N \) timesteps. If the `time` value is `clock`, then the simulation runs until \( N \) aggregate timesteps across all replicas have elapsed. This aggregate time is the “clock” time defined below, which typically advances nearly \( M \) times faster than the timestepping on a single replica, where \( M \) is the number of replicas.

Four kinds of output can be generated during a PRD run: event statistics, thermodynamic output by each replica, dump files, and restart files.

When running with multiple partitions (each of which is a replica in this case), the print-out to the screen and master log.lammps file is limited to event statistics. Note that if a PRD run is performed on only a single replica then the event statistics will be intermixed with the usual thermodynamic output discussed below.

The quantities printed each time an event occurs are the timestep, CPU time, clock, event number, a correlation flag, the number of coincident events, and the replica number of the chosen event.

The timestep is the usual LAMMPS timestep, except that time does not advance during dephasing or quenches, but only during dynamics. Note that there are two kinds of dynamics in the PRD loop listed above that contribute to this timestepping. The first is when all replicas are performing independent dynamics, waiting for an event to occur. The second is when correlated events are being searched for, but only one replica is running dynamics.

The CPU time is the total elapsed time on each processor, since the start of the PRD run.

The clock is the same as the timestep except that it advances by \( M \) steps per timestep during the first kind of dynamics when the \( M \) replicas are running independently. The clock advances by only 1 step per timestep during the second kind of dynamics, when only a single replica is checking for a correlated event. Thus “clock” time represents the aggregate time (in steps) that has effectively elapsed during a PRD simulation on \( M \) replicas. If most of the PRD run is spent in the second stage of the loop above, searching for infrequent events, then the clock will advance nearly \( M \) times faster than it would if a single replica was running. Note the clock time between successive events should be drawn from \( p(t) \).

The event number is a counter that increments with each event, whether it is uncorrelated or correlated.

The correlation flag will be 0 when an uncorrelated event occurs during the second stage of the loop listed above, i.e. when all replicas are running independently. The correlation flag will be 1 when a correlated event occurs during the third stage of the loop listed above, i.e. when only one replica is running dynamics.

When more than one replica detects an event at the end of the same event check (every \( t_{\text{event}} \) steps) during the second stage, then one of them is chosen at random. The number of coincident events is the number of replicas that detected an event. Normally, this value should be 1. If it is often greater than 1, then either the number of replicas is too large, or \( t_{\text{event}} \) is too large.

The replica number is the ID of the replica (from 0 to \( M-1 \)) in which the event occurred.

When running on multiple partitions, LAMMPS produces additional log files for each partition, e.g. log.lammps.0, log.lammps.1, etc. For the PRD command, these contain the thermodynamic output for each replica. You will see short
runs and minimizations corresponding to the dynamics and quench operations of the loop listed above. The timestep will be reset appropriately depending on whether the operation advances time or not.

After the PRD command completes, timing statistics for the PRD run are printed in each replica’s log file, giving a breakdown of how much CPU time was spent in each stage (dephasing, dynamics, quenching, etc).

Any dump files defined in the input script, will be written to during a PRD run at timesteps corresponding to both uncorrelated and correlated events. This means the requested dump frequency in the dump command is ignored. There will be one dump file (per dump command) created for all partitions.

The atom coordinates of the dump snapshot are those of the minimum energy configuration resulting from quenching following a transition event. The timesteps written into the dump files correspond to the timestep at which the event occurred and NOT the clock. A dump snapshot corresponding to the initial minimum state used for event detection is written to the dump file at the beginning of each PRD run.

If the restart command is used, a single restart file for all the partitions is generated, which allows a PRD run to be continued by a new input script in the usual manner.

The restart file is generated at the end of the loop listed above. If no correlated events are found, this means it contains a snapshot of the system at time $T + t_{correlate}$, where $T$ is the time at which the uncorrelated event occurred. If correlated events were found, then it contains a snapshot of the system at time $T + t_{correlate}$, where $T$ is the time of the last correlated event.

The restart frequency specified in the restart command is interpreted differently when performing a PRD run. It does not mean the timestep interval between restart files. Instead it means an event interval for uncorrelated events. Thus a frequency of 1 means write a restart file every time an uncorrelated event occurs. A frequency of 10 means write a restart file every 10th uncorrelated event.

When an input script reads a restart file from a previous PRD run, the new script can be run on a different number of replicas or processors. However, it is assumed that $t_{correlate}$ in the new PRD command is the same as it was previously. If not, the calculation of the “clock” value for the first event in the new run will be slightly off.

16.100.4 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the Build package doc page for more info.

The $N$ and $t_{correlate}$ settings must be integer multiples of $t_{event}$.

Runs restarted from restart file written during a PRD run will not produce identical results due to changes in the random numbers used for dephasing.

This command cannot be used when any fixes are defined that keep track of elapsed time to perform time-dependent operations. Examples include the “ave” fixes such as fix ave/chunk. Also fix dt/reset and fix deposit.
16.100.5 Related commands

compute event/displace, min_modify, min_style, run_style, minimize, velocity, temper, neb, tad, hyper

16.100.6 Default

The option defaults are min = 0.1 0.1 40 50, no temp setting, vel = geom gaussian, and time = steps.

16.101 print command

16.101.1 Syntax

`print string keyword value`

- string = text string to print, which may contain variables
- zero or more keyword/value pairs may be appended
- keyword = file or append or screen or universe

`file value = filename`
`append value = filename`
`screen value = yes or no`
`universe value = yes or no`

16.101.2 Examples

```
print "Done with equilibration" file info.dat
print Vol=$v append info.dat screen no
print "The system volume is now $v"
print 'The system volume is now $v'
print "NEB calculation 1 complete" screen no universe yes
print "System volume = $v
System temperature = $t
""
```
16.101.3 Description

Print a text string to the screen and logfile. The text string must be a single argument, so if it is one line but more than one word, it should be enclosed in single or double quotes. To generate multiple lines of output, the string can be enclosed in triple quotes, as in the last example above. If the text string contains variables, they will be evaluated and their current values printed.

Note: As discussed on the Commands parse doc page, the text string can use “immediate” variables, specified as $(formula) with parenthesis, where the numeric formula has the same syntax as equal-style variables described on the variable doc page. This is a convenient way to evaluate a formula immediately without using the variable command to define a named variable and then use that variable in the text string. The formula can include a trailing colon and format string which determines the precision with which the numeric value is output. This is also explained on the Commands parse doc page.

If the file or append keyword is used, a filename is specified to which the output will be written. If file is used, then the filename is overwritten if it already exists. If append is used, then the filename is appended to if it already exists, or created if it does not exist.

If the screen keyword is used, output to the screen and logfile can be turned on or off as desired.

If the universe keyword is used, output to the global screen and logfile can be turned on or off as desired. In multi-partition calculations, the screen option and the corresponding output only apply to the screen and logfile of the individual partition.

If you want the print command to be executed multiple times (with changing variable values), there are 3 options. First, consider using the fix print command, which will print a string periodically during a simulation. Second, the print command can be used as an argument to the every option of the run command. Third, the print command could appear in a section of the input script that is looped over (see the jump and next commands).

See the variable command for a description of equal style variables which are typically the most useful ones to use with the print command. Equal-style variables can calculate formulas involving mathematical operations, atom properties, group properties, thermodynamic properties, global values calculated by a compute or fix, or references to other variables.

16.101.4 Restrictions

none

16.101.5 Related commands

16.102.3 Description

Specify how processors are mapped as a regular 3d grid to the global simulation box. The mapping involves 2 steps. First, if there are \( P \) processors it means choosing a factorization \( P = P_x \times P_y \times P_z \) so that there are \( P_x \) processors in the x dimension, and similarly for the y and z dimensions. Second, the \( P \) processors are mapped to the regular 3d grid. The arguments to this command control each of these 2 steps.

The \( P_x, P_y, P_z \) parameters affect the factorization. Any of the 3 parameters can be specified with an asterisk “*”, which means LAMMPS will choose the number of processors in that dimension of the grid. It will do this based on the size and shape of the global simulation box so as to minimize the surface-to-volume ratio of each processor’s sub-domain.

Choosing explicit values for \( P_x \) or \( P_y \) or \( P_z \) can be used to override the default manner in which LAMMPS will create the regular 3d grid of processors, if it is known to be sub-optimal for a particular problem. E.g. a problem where the extent of atoms will change dramatically in a particular dimension over the course of the simulation.

The product of \( P_x, P_y, P_z \) must equal \( P \), the total \# of processors LAMMPS is running on. For a 2d simulation, \( P_z \) must equal 1.

Note that if you run on a prime number of processors \( P \), then a grid such as \( 1 \times P \times 1 \) will be required, which may incur extra communication costs due to the high surface area of each processor’s sub-domain.

Also note that if multiple partitions are being used then \( P \) is the number of processors in this partition; see the \texttt{-partition} command-line switch page for details. Also note that you can prefix the processors command with the \texttt{partition} command to easily specify different \( P_x, P_y, P_z \) values for different partitions.

You can use the \texttt{partition} command to specify different processor grids for different partitions, e.g.

```
partition yes 1 processors 4 4 4
partition yes 2 processors 2 3 2
```

\textbf{Note:} This command only affects the initial regular 3d grid created when the simulation box is first specified via a \texttt{create_box} or \texttt{read_data} or \texttt{read_restart} command. Or if the simulation box is re-created via the \texttt{replicate} command. The same regular grid is initially created, regardless of which \texttt{comm_style} command is in effect.

If load-balancing is never invoked via the \texttt{balance} or \texttt{fix balance} commands, then the initial regular grid will persist for all simulations. If balancing is performed, some of the methods invoked by those commands retain the logical topology of the initial 3d grid, and the mapping of processors to the grid specified by the processors command. However the grid spacings in different dimensions may change, so that processors own sub-domains of different sizes. If the \texttt{comm_style tiled} command is used, methods invoked by the balancing commands may discard the 3d grid of processors and tile the simulation domain with sub-domains of different sizes and shapes which no longer have a logical 3d connectivity. If that occurs, all the information specified by the processors command is ignored.

The \texttt{grid} keyword affects the factorization of \( P \) into \( P_x, P_y, P_z \) and it can also affect how the \( P \) processor IDs are mapped to the 3d grid of processors.

The \texttt{onelevel} style creates a 3d grid that is compatible with the \( P_x, P_y, P_z \) settings, and which minimizes the surface-to-volume ratio of each processor’s sub-domain, as described above. The mapping of processors to the grid is determined by the \texttt{map} keyword setting.

The \texttt{twolevel} style can be used on machines with multicore nodes to minimize off-node communication. It insures that contiguous sub-sections of the 3d grid are assigned to all the cores of a node. For example if \( N_c \) is 4, then \( 2 \times 2 \times 1 \) or \( 2 \times 1 \times 2 \) or \( 1 \times 2 \times 2 \) sub-sections of the 3d grid will correspond to the cores of each node. This affects both the factorization and mapping steps.

The \( C_x, C_y, C_z \) settings are similar to the \( P_x, P_y, P_z \) settings, only their product should equal \( N_c \). Any of the 3 parameters can be specified with an asterisk “*”, which means LAMMPS will choose the number of cores in that dimension of
the node’s sub-grid. As with Px, Py, Pz, it will do this based on the size and shape of the global simulation box so as to
minimize the surface-to-volume ratio of each processor’s sub-domain.

**Note:** For the `twlevel` style to work correctly, it assumes the MPI ranks of processors LAMMPS is running on are
ordered by core and then by node. E.g. if you are running on 2 quad-core nodes, for a total of 8 processors, then it
assumes processors 0,1,2,3 are on node 1, and processors 4,5,6,7 are on node 2. This is the default rank ordering for
most MPI implementations, but some MPIs provide options for this ordering, e.g. via environment variable settings.

The `numa` style operates similar to the `twlevel` keyword except that it auto-detects which cores are running on which
nodes. Currently, it does this in only 2 levels, but it may be extended in the future to account for socket topology and
other non-uniform memory access (NUMA) costs. It also uses a different algorithm than the `twlevel` keyword for
doing the two-level factorization of the simulation box into a 3d processor grid to minimize off-node communication,
and it does its own MPI-based mapping of nodes and cores to the regular 3d grid. Thus it may produce a different
layout of the processors than the `twlevel` options.

The `numa` style will give an error if the number of MPI processes is not divisible by the number of cores used per node,
or any of the Px or Py of Pz values is greater than 1.

**Note:** Unlike the `twlevel` style, the `numa` style does not require any particular ordering of MPI ranks in order to work
correctly. This is because it auto-detects which processes are running on which nodes.

The `custom` style uses the file `infile` to define both the 3d factorization and the mapping of processors to the grid.

The file should have the following format. Any number of initial blank or comment lines (starting with a “#” character)
can be present. The first non-blank, non-comment line should have 3 values:

```
Px  Py  Py
```

These must be compatible with the total number of processors and the Px, Py, Pz settings of the processors command.
This line should be immediately followed by `P = Px*Py*Pz` lines of the form:

```
ID  I  J  K
```

where ID is a processor ID (from 0 to P-1) and I, J, K are the processors location in the 3d grid. I must be a number
from 1 to Px (inclusive) and similarly for J and K. The P lines can be listed in any order, but no processor ID should
appear more than once.

The `map` keyword affects how the P processor IDs (from 0 to P-1) are mapped to the 3d grid of processors. It is only
used by the `onelvel` and `twlevel` grid settings.

The `cart` style uses the family of MPI Cartesian functions to perform the mapping, namely `MPI_Cart_create()`,
`MPI_Cart_get()`, `MPI_Cart_shift()`, and `MPI_Cart_rank()`. It invokes the `MPI_Cart_create()` function with its reorder
flag = 0, so that MPI is not free to reorder the processors.

The `cart/reorder` style does the same thing as the `cart` style except it sets the reorder flag to 1, so that MPI can reorder
processors if it desires.

The `xyz`, `xzy`, `yxz`, `yzx`, `zxy`, and `zyx` styles are all similar. If the style is IJK, then it maps the P processors to the grid
so that the processor ID in the I direction varies fastest, the processor ID in the J direction varies next fastest, and the
processor ID in the K direction varies slowest. For example, if you select style `xyz` and you have a 2x2x2 grid of 8
processors, the assignments of the 8 octants of the simulation domain will be:
Note that, in principle, an MPI implementation on a particular machine should be aware of both the machine’s network topology and the specific subset of processors and nodes that were assigned to your simulation. Thus its MPI_Cart calls can optimize the assignment of MPI processes to the 3d grid to minimize communication costs. In practice, however, few if any MPI implementations actually do this. So it is likely that the cart and cart/reorder styles simply give the same result as one of the IJK styles.

Also note, that for the twolevel grid style, the map setting is used to first map the nodes to the 3d grid, then again to the cores within each node. For the latter step, the cart and cart/reorder styles are not supported, so an xyz style is used in their place.

The part keyword affects the factorization of P into Px,Py,Pz.

It can be useful when running in multi-partition mode, e.g. with the run_style verlet/split command. It specifies a dependency between a sending partition Psend and a receiving partition Precv which is enforced when each is setting up their own mapping of their processors to the simulation box. Each of Psend and Precv must be integers from 1 to Np, where Np is the number of partitions you have defined via the -partition command-line switch.

A “dependency” means that the sending partition will create its regular 3d grid as Px by Py by Pz and after it has done this, it will send the Px,Py,Pz values to the receiving partition. The receiving partition will wait to receive these values before creating its own regular 3d grid and will use the sender’s Px,Py,Pz values as a constraint. The nature of the constraint is determined by the cstyle argument.

For a cstyle of multiple, each dimension of the sender’s processor grid is required to be an integer multiple of the corresponding dimension in the receiver’s processor grid. This is a requirement of the run_style verlet/split command.

For example, assume the sending partition creates a 4x6x10 grid = 240 processor grid. If the receiving partition is running on 80 processors, it could create a 4x2x10 grid, but it will not create a 2x4x10 grid, since in the y-dimension, 6 is not an integer multiple of 4.

Note: If you use the partition command to invoke different “processors” commands on different partitions, and you also use the part keyword, then you must insure that both the sending and receiving partitions invoke the “processors” command that connects the 2 partitions via the part keyword. LAMMPS cannot easily check for this, but your simulation will likely hang in its setup phase if this error has been made.

The file keyword writes the mapping of the factorization of P processors and their mapping to the 3d grid to the specified file outfile. This is useful to check that you assigned physical processors in the manner you desired, which can be tricky to figure out, especially when running on multiple partitions or on, a multicore machine or when the processor ranks were reordered by use of the -reorder command-line switch or due to use of MPI-specific launch options such as a config file.

If you have multiple partitions you should insure that each one writes to a different file, e.g. using a world-style variable for the filename. The file has a self-explanatory header, followed by one-line per processor in this format:

world-ID universe-ID original-ID: I J K: name
The IDs are the processor’s rank in this simulation (the world), the universe (of multiple simulations), and the original MPI communicator used to instantiate LAMMPS, respectively. The world and universe IDs will only be different if you are running on more than one partition; see the -partition command-line switch. The universe and original IDs will only be different if you used the -reorder command-line switch to reorder the processors differently than their rank in the original communicator LAMMPS was instantiated with.

I,J,K are the indices of the processor in the regular 3d grid, each from 1 to Nd, where Nd is the number of processors in that dimension of the grid.

The name is what is returned by a call to MPI_Get_processor_name() and should represent an identifier relevant to the physical processors in your machine. Note that depending on the MPI implementation, multiple cores can have the same name.

16.102.4 Restrictions

This command cannot be used after the simulation box is defined by a read_data or create_box command. It can be used before a restart file is read to change the 3d processor grid from what is specified in the restart file.

The grid numa keyword only currently works with the map cart option.

The part keyword (for the receiving partition) only works with the grid onelevel or grid twolevel options.

inline = one or more lines of Python code which defines func
must be a single argument, typically enclosed between triple quotes

exists arg = none = Python code has been loaded by previous python command

source arg = filename or inline
filename = file of Python code which will be executed immediately
inline = one or more lines of Python code which will be executed immediately
must be a single argument, typically enclosed between triple quotes

16.103.2 Examples

```
python  pForce input 2 v_x 20.0 return v_f format fff file force.py
python  pForce invoke

python  factorial input 1 myN return v_fac format ii here ""
    def factorial(n):
        if n == 1: return n
        return n * factorial(n-1)
    ""

python  loop input 1 SELF return v_value format pf here ""
    def loop(lmpptr,N,cut0):
        from lammps import lammps
        lmp = lammps(ptr=lmpptr)
        # loop N times, increasing cutoff each time
        for i in range(N):
            cut = cut0 + i*0.1
            lmp.set_variable("cut",cut)  # set a variable in LAMMPS
            lmp.command("pair_style lj/cut ${cut}")  # LAMMPS commands
            lmp.command("pair_coeff * * 1.0 1.0")
            lmp.command("run 100")
    ""
```
16.103.3 Description

Define a Python function or execute a previously defined function or execute some arbitrary python code. Arguments, including LAMMPS variables, can be passed to the function from the LAMMPS input script and a value returned by the Python function to a LAMMPS variable. The Python code for the function can be included directly in the input script or in a separate Python file. The function can be standard Python code or it can make “callbacks” to LAMMPS through its library interface to query or set internal values within LAMMPS. This is a powerful mechanism for performing complex operations in a LAMMPS input script that are not possible with the simple input script and variable syntax which LAMMPS defines. Thus your input script can operate more like a true programming language.

Use of this command requires building LAMMPS with the PYTHON package which links to the Python library so that the Python interpreter is embedded in LAMMPS. More details about this process are given below.

There are two ways to invoke a Python function once it has been defined. One is using the `invoke` keyword. The other is to assign the function to a python-style variable defined in your input script. Whenever the variable is evaluated, it will execute the Python function to assign a value to the variable. Note that variables can be evaluated in many different ways within LAMMPS. They can be substituted for directly in an input script. Or they can be passed to various commands as arguments, so that the variable is evaluated during a simulation run.

A broader overview of how Python can be used with LAMMPS is given on the Python doc page. There is an examples/python directory which illustrates use of the python command.

The `func` setting specifies the name of the Python function. The code for the function is defined using the `file` or `here` keywords as explained below. In case of the `source` keyword, the name of the function is ignored.

If the `invoke` keyword is used, no other keywords can be used, and a previous python command must have defined the Python function referenced by this command. This invokes the Python function with the previously defined arguments and return value processed as explained below. You can invoke the function as many times as you wish in your input script.

If the `source` keyword is used, no other keywords can be used. The argument can be a filename or a string with python commands, either on a single line enclosed in quotes, or as multiple lines enclosed in triple quotes. These python commands will be passed to the python interpreter and executed immediately without registering a python function for future execution.

The `input` keyword defines how many arguments $N$ the Python function expects. If it takes no arguments, then the `input` keyword should not be used. Each argument can be specified directly as a value, e.g. 6 or 3.14159 or abc (a string of characters). The type of each argument is specified by the `format` keyword as explained below, so that Python will know how to interpret the value. If the word SELF is used for an argument it has a special meaning. A pointer is passed to the Python function which it converts into a reference to LAMMPS itself. This enables the function to call back to LAMMPS through its library interface as explained below. This allows the Python function to query or set values internal to LAMMPS which can affect the subsequent execution of the input script. A LAMMPS variable can also be used as an argument, specified as `v_name`, where “name” is the name of the variable. Any style of LAMMPS variable can be used, as defined by the `variable` command. Each time the Python function is invoked, the LAMMPS variable is evaluated and its value is passed to the Python function.

The `return` keyword is only needed if the Python function returns a value. The specified `varReturn` must be of the form `v_name`, where “name” is the name of a python-style LAMMPS variable, defined by the `variable` command. The Python function can return a numeric or string value, as specified by the `format` keyword.

As explained on the `variable` doc page, the definition of a python-style variable associates a Python function name with the variable. This must match the `func` setting for this command. For example these two commands would be self-consistent:

```
variable foo python myMultiply
python myMultiply return v/foo format f file funcs.py
```
The two commands can appear in either order in the input script so long as both are specified before the Python function is invoked for the first time.

The `format` keyword must be used if the `input` or `return` keyword is used. It defines an f-string with M characters, where M = sum of number of inputs and outputs. The order of characters corresponds to the N inputs, followed by the return value (if it exists). Each character must be one of the following: “i” for integer, “f” for floating point, “s” for string, or “p” for SELF. Each character defines the type of the corresponding input or output value of the Python function and affects the type conversion that is performed internally as data is passed back and forth between LAMMPS and Python.

Note that it is permissible to use a `python-style variable` in a LAMMPS command that allows for an equal-style variable as an argument, but only if the output of the Python function is flagged as a numeric value (“i” or “f”) via the `format` keyword.

If the `return` keyword is used and the `format` keyword specifies the output as a string, then the default maximum length of that string is 63 characters (64-1 for the string terminator). If you want to return a longer string, the `length` keyword can be specified with its Nlen value set to a larger number (the code allocates space for Nlen+1 to include the string terminator). If the Python function generates a string longer than the default 63 or the specified `Nlen`, it will be truncated.

Either the `file`, `here`, or `exists` keyword must be used, but only one of them. These keywords specify what Python code to load into the Python interpreter. The `file` keyword gives the name of a file, which should end with a `.py` suffix, which contains Python code. The code will be immediately loaded into and run in the “main” module of the Python interpreter. Note that Python code which contains a function definition does not “execute” the function when it is run; it simply defines the function so that it can be invoked later.

The `here` keyword does the same thing, except that the Python code follows as a single argument to the `here` keyword. This can be done using triple quotes as delimiters, as in the examples above. This allows Python code to be listed verbatim in your input script, with proper indentation, blank lines, and comments, as desired. See the `Commands parse` doc page, for an explanation of how triple quotes can be used as part of input script syntax.

The `exists` keyword takes no argument. It means that Python code containing the required Python function defined by the `func` setting, is assumed to have been previously loaded by another python command.

Note that the Python code that is loaded and run must contain a function with the specified `func` name. To operate properly when later invoked, the function code must match the `input` and `return` and `format` keywords specified by the python command. Otherwise Python will generate an error.

This section describes how Python code can be written to work with LAMMPS.

Whether you load Python code from a file or directly from your input script, via the `file` and `here` keywords, the code can be identical. It must be indented properly as Python requires. It can contain comments or blank lines. If the code is in your input script, it cannot however contain triple-quoted Python strings, since that will conflict with the triple-quote parsing that the LAMMPS input script performs.

All the Python code you specify via one or more python commands is loaded into the Python “main” module, i.e. `__main__`. The code can define global variables or statements that are outside of function definitions. It can contain multiple functions, only one of which matches the `func` setting in the python command. This means you can use the `file` keyword once to load several functions, and the `exists` keyword thereafter in subsequent python commands to access the other functions previously loaded.

A Python function you define (or more generally, the code you load) can import other Python modules or classes, it can make calls to other system functions or functions you define, and it can access or modify global variables (in the “main” module) which will persist between successive function calls. The latter can be useful, for example, to prevent a function from being invoke multiple times per timestep by different commands in a LAMMPS input script that access the returned python-style variable associated with the function. For example, consider this function loaded with two global variables defined outside the function:
nsteplast = -1
nvaluelast = 0

def expensive(nstep):
    global nsteplast, nvaluelast
    if nstep == nsteplast: return nvaluelast
    nsteplast = nstep
    # perform complicated calculation
    nvalue = ...
    nvaluelast = nvalue
    return nvalue

Nsteplast stores the previous timestep the function was invoked (passed as an argument to the function). Nvaluelast stores the return value computed on the last function invocation. If the function is invoked again on the same timestep, the previous value is simply returned, without re-computing it. The “global” statement inside the Python function allows it to overwrite the global variables.

Note that if you load Python code multiple times (via multiple python commands), you can overwrite previously loaded variables and functions if you are not careful. E.g. if the code above were loaded twice, the global variables would be re-initialized, which might not be what you want. Likewise, if a function with the same name exists in two chunks of Python code you load, the function loaded second will override the function loaded first.

It’s important to realize that if you are running LAMMPS in parallel, each MPI task will load the Python interpreter and execute a local copy of the Python function(s) you define. There is no connection between the Python interpreters running on different processors. This implies three important things.

First, if you put a print statement in your Python function, you will see P copies of the output, when running on P processors. If the prints occur at (nearly) the same time, the P copies of the output may be mixed together. Welcome to the world of parallel programming and debugging.

Second, if your Python code loads modules that are not pre-loaded by the Python library, then it will load the module from disk. This may be a bottleneck if 1000s of processors try to load a module at the same time. On some large supercomputers, loading of modules from disk by Python may be disabled. In this case you would need to pre-build a Python library that has the required modules pre-loaded and link LAMMPS with that library.

Third, if your Python code calls back to LAMMPS (discussed in the next section) and causes LAMMPS to perform an MPI operation requires global communication (e.g. via MPI_Allreduce), such as computing the global temperature of the system, then you must insure all your Python functions (running independently on different processors) call back to LAMMPS. Otherwise the code may hang.

Your Python function can “call back” to LAMMPS through its library interface, if you use the SELF input to pass Python a pointer to LAMMPS. The mechanism for doing this in your Python function is as follows:

def foo(lmpptr,...):
    from lammps import lammps
    lmp = lammps(ptr=lmpptr)
    lmp.command('print "Hello from inside Python"')
    ...

The function definition must include a variable (lmpptr in this case) which corresponds to SELF in the python command. The first line of the function imports the “lammps” Python module. The second line creates a Python object lmp which wraps the instance of LAMMPS that called the function. The “ptr=lmpptr” argument is what makes that happen. The third line invokes the command() function in the LAMMPS library interface. It takes a single string argument which is a LAMMPS input script command for LAMMPS to execute, the same as if it appeared in your input script. In this case, LAMMPS should output
Hello from inside Python

to the screen and log file. Note that since the LAMMPS print command itself takes a string in quotes as its argument, the Python string must be delimited with a different style of quotes.

The Use Python with LAMMPS page describes the syntax for how Python wraps the various functions included in the LAMMPS library interface.

A more interesting example is in the examples/python/in.python script which loads and runs the following function from examples/python/funcs.py:

```python
def loop(N,cut0,thresh,lmpptr):
    print("LOOP ARGS", N, cut0, thresh, lmpptr)
    from lammps import lammps
    lmp = lammps(ptr=lmpptr)
    natoms = lmp.get_natoms()
    for i in range(N):
        cut = cut0 + i*0.1
        lmp.set_variable("cut",cut)  # set a variable in LAMMPS
        lmp.command("pair_style lj/cut ${cut}" )  # LAMMPS command
        lmp.command("pair_style lj/cut %d %d")  # LAMMPS command option
        lmp.command("pair_coeff * * 1.0 1.0")  # ditto
        lmp.command("run 10")  # ditto
        pe = lmp.extract_compute("thermo_pe",0,0)  # extract total PE from LAMMPS
        print("PE", pe/natoms, thresh)
        if pe/natoms < thresh: return
```

with these input script commands:

```bash
cpython loop input 4 10 1.0 -4.0 SELF format iffp file funcs.py
cpython loop invoke
```

This has the effect of looping over a series of 10 short runs (10 timesteps each) where the pair style cutoff is increased from a value of 1.0 in distance units, in increments of 0.1. The looping stops when the per-atom potential energy falls below a threshold of -4.0 in energy units. More generally, Python can be used to implement a loop with complex logic, much more so than can be created using the LAMMPS jump and if commands.

Several LAMMPS library functions are called from the loop function. Get_natoms() returns the number of atoms in the simulation, so that it can be used to normalize the potential energy that is returned by extract_compute() for the “thermo_pe” compute that is defined by default for LAMMPS thermodynamic output. Set_variable() sets the value of a string variable defined in LAMMPS. This library function is a useful way for a Python function to return multiple values to LAMMPS, more than the single value that can be passed back via a return statement. This cutoff value in the “cut” variable is then substituted (by LAMMPS) in the pair_style command that is executed next. Alternatively, the “LAMMPS command option” line could be used in place of the 2 preceding lines, to have Python insert the value into the LAMMPS command string.

Note: When using the callback mechanism just described, recognize that there are some operations you should not attempt because LAMMPS cannot execute them correctly. If the Python function is invoked between runs in the LAMMPS input script, then it should be OK to invoke any LAMMPS input script command via the library interface command() or file() functions, so long as the command would work if it were executed in the LAMMPS input script directly at the same point.
However, a Python function can also be invoked during a run, whenever an associated LAMMPS variable it is assigned to is evaluated. If the variable is an input argument to another LAMMPS command (e.g. `fix setforce`), then the Python function will be invoked inside the class for that command, in one of its methods that is invoked in the middle of a timestep. You cannot execute arbitrary input script commands from the Python function (again, via the `command()` or `file()` functions) at that point in the run and expect it to work. Other library functions such as those that invoke computes or other variables may have hidden side effects as well. In these cases, LAMMPS has no simple way to check that something illogical is being attempted.

The same applies to Python functions called during a simulation run at each time step using `fix python/invoke`.

If you run Python code directly on your workstation, either interactively or by using Python to launch a Python script stored in a file, and your code has an error, you will typically see informative error messages. That is not the case when you run Python code from LAMMPS using an embedded Python interpreter. The code will typically fail silently. LAMMPS will catch some errors but cannot tell you where in the Python code the problem occurred. For example, if the Python code cannot be loaded and run because it has syntax or other logic errors, you may get an error from Python pointing to the offending line, or you may get one of these generic errors from LAMMPS:

```
Could not process Python file
Could not process Python string
```

When the Python function is invoked, if it does not return properly, you will typically get this generic error from LAMMPS:

```
Python function evaluation failed
```

Here are three suggestions for debugging your Python code while running it under LAMMPS.

First, don’t run it under LAMMPS, at least to start with! Debug it using plain Python. Load and invoke your function, pass it arguments, check return values, etc.

Second, add Python print statements to the function to check how far it gets and intermediate values it calculates. See the discussion above about printing from Python when running in parallel.

Third, use Python exception handling. For example, say this statement in your Python function is failing, because you have not initialized the variable `foo`:

```
foo += 1
```

If you put one (or more) statements inside a “try” statement, like this:

```
import exceptions
print("Inside simple function")
try:
    foo += 1               # one or more statements here
except Exception as e:
    print("FOO error:", e)
```

then you will get this message printed to the screen:

```
FOO error: local variable 'foo' referenced before assignment
```

If there is no error in the try statements, then nothing is printed. Either way the function continues on (unless you put a return or `sys.exit()` in the except clause).
16.103.4 Restrictions

This command is part of the PYTHON package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

Building LAMMPS with the PYTHON package will link LAMMPS with the Python library on your system. Settings to enable this are in the lib/python/Makefile.lammps file. See the lib/python/README file for information on those settings.

If you use Python code which calls back to LAMMPS, via the SELF input argument explained above, there is an extra step required when building LAMMPS. LAMMPS must also be built as a shared library and your Python function must be able to load the “lammps” Python module that wraps the LAMMPS library interface. These are the same steps required to use Python by itself to wrap LAMMPS. Details on these steps are explained on the Python doc page. Note that it is important that the stand-alone LAMMPS executable and the LAMMPS shared library be consistent (built from the same source code files) in order for this to work. If the two have been built at different times using different source files, problems may occur.

16.104 quit command

16.104.1 Syntax

quit status

status = numerical exit status (optional)

16.104.2 Examples

| quit | if "$n > 10000" then "quit 1"

16.104.3 Description

This command causes LAMMPS to exit, after shutting down all output cleanly.

It can be used as a debug statement in an input script, to terminate the script at some intermediate point.

It can also be used as an invoked command inside the “then” or “else” portion of an if command.

The optional status argument is an integer which signals the return status to a program calling LAMMPS. A return status of 0 usually indicates success. A status != 0 is failure, where the specified value can be used to distinguish the kind of error, e.g. where in the input script the quit was invoked. If not specified, a status of 0 is returned.

16.105.3 Description

Read in a data file containing information LAMMPS needs to run a simulation. The file can be ASCII text or a gzipped text file (detected by a .gz suffix). This is one of 3 ways to specify initial atom coordinates; see the read_restart and create_atoms commands for alternative methods. Also see the explanation of the -restart command-line switch which can convert a restart file to a data file.

This command can be used multiple times to add new atoms and their properties to an existing system by using the add, offset, and shift keywords. See more details below, which includes the use case for the extra keywords.

The group keyword adds all the atoms in the data file to the specified group-ID. The group will be created if it does not already exist. This is useful if you are reading multiple data files and wish to put sets of atoms into different groups so they can be operated on later. E.g. a group of added atoms can be moved to new positions via the displace_atoms command. Note that atoms read from the data file are also always added to the “all” group. The group command discusses atom groups, as used in LAMMPS.

The nocoeff keyword tells read_data to ignore force field parameters. The various Coeff sections are still read and have to have the correct number of lines, but they are not applied. This also allows to read a data file without having any pair, bond, angle, dihedral or improper styles defined, or to read a data file for a different force field.

The use of the fix keyword is discussed below.

16.105.4 Reading multiple data files

The read_data command can be used multiple times with the same or different data files to build up a complex system from components contained in individual data files. For example one data file could contain fluid in a confined domain; a second could contain wall atoms, and the second file could be read a third time to create a wall on the other side of the fluid. The third set of atoms could be rotated to an opposing direction using the displace_atoms command, after the third read_data command is used.

The add, offset, shift, extra, and group keywords are useful in this context.

If a simulation box does not yet exist, the add keyword cannot be used; the read_data command is being used for the first time. If a simulation box does exist, due to using the create_box command, or a previous read_data command, then the add keyword must be used.
**Note:** The simulation box size (xlo to xhi, ylo to yhi, zlo to zhi) in the new data file will be merged with the existing simulation box to create a large enough box in each dimension to contain both the existing and new atoms. Each box dimension never shrinks due to this merge operation, it only stays the same or grows. Care must be used if you are growing the existing simulation box in a periodic dimension. If there are existing atoms with bonds that straddle that periodic boundary, then the atoms may become far apart if the box size grows. This will separate the atoms in the bond, which can lead to “lost” bond atoms or bad dynamics.

The three choices for the `add` argument affect how the atom IDs and molecule IDs of atoms in the data file are treated. If `append` is specified, atoms in the data file are added to the current system, with their atom IDs reset so that an atom-ID = M in the data file becomes atom-ID = N+M, where N is the largest atom ID in the current system. This rule is applied to all occurrences of atom IDs in the data file, e.g. in the Velocity or Bonds section. This is also done for molecule IDs, if the atom style does support molecule IDs or they are enabled via fix property/atom. If IDoffset is specified, then IDoffset is a numeric value is given, e.g. 1000, so that an atom-ID = M in the data file becomes atom-ID = 1000+M. For systems with enabled molecule IDs, another numerical argument MOLoffset is required representing the equivalent offset for molecule IDs. If `merge` is specified, the data file atoms are added to the current system without changing their IDs. They are assumed to merge (without duplication) with the currently defined atoms. It is up to you to insure there are no multiply defined atom IDs, as LAMMPS only performs an incomplete check that this is the case by insuring the resulting max atom-ID >= the number of atoms. For molecule IDs, there is no check done at all.

The `offset` and `shift` keywords can only be used if the `add` keyword is also specified.

The `offset` keyword adds the specified offset values to the atom types, bond types, angle types, dihedral types, and improper types as they are read from the data file. E.g. if `off` = 2, and the file uses atom types 1,2,3, then the added atoms will have atom types 3,4,5. These offsets apply to all occurrences of types in the data file, e.g. for the Atoms or Masses or Pair Coeffs or Bond Coeffs sections. This makes it easy to use atoms and molecules and their attributes from a data file in different simulations, where you want their types (atom, bond, angle, etc) to be different depending on what other types already exist. All five offset values must be specified, but individual values will be ignored if the data file does not use that attribute (e.g. no bonds).

The `shift` keyword can be used to specify an (Sx, Sy, Sz) displacement applied to the coordinates of each atom. Sz must be 0.0 for a 2d simulation. This is a mechanism for adding structured collections of atoms at different locations within the simulation box, to build up a complex geometry. It is up to you to insure atoms do not end up overlapping unphysically which would lead to bad dynamics. Note that the `displace_atoms` command can be used to move a subset of atoms after they have been read from a data file. Likewise, the `delete_atoms` command can be used to remove overlapping atoms. Note that the shift values (Sx, Sy, Sz) are also added to the simulation box information (xlo, ylo, yhi, zlo, zhi) in the data file to shift its boundaries. E.g. `xlo_new = xlo + Sx, xhi_new = xhi + Sx`.

The `extra` keywords can only be used the first time the `read_data` command is used. They are useful if you intend to add new atom, bond, angle, etc types later with additional `read_data` commands. This is because the maximum number of allowed atom, bond, angle, etc types is set by LAMMPS when the system is first initialized. If you do not use the `extra` keywords, then the number of these types will be limited to what appears in the first data file you read. For example, if the first data file is a solid substrate of Si, it will likely specify a single atom type. If you read a second data file with a different material (water molecules) that sit on top of the substrate, you will want to use different atom types for those atoms. You can only do this if you set the `extra/atom/types` keyword to a sufficiently large value when reading the substrate data file. Note that use of the `extra` keywords also allows each data file to contain sections like Masses or Pair Coeffs or Bond Coeffs which are sized appropriately for the number of types in that data file. If the `offset` keyword is used appropriately when each data file is read, the values in those sections will be stored correctly in the larger data structures allocated by the use of the `extra` keywords. E.g. the substrate file can list mass and pair coefficients for type 1 silicon atoms. The water file can list mass and pair coefficients for type 1 and type 2 hydrogen and oxygen atoms. Use of the `extra` and `offset` keywords will store those mass and pair coefficient values appropriately in data structures that allow for 3 atom types (Si, H, O). Of course, you would still need to specify coefficients for H/Si and O/Si interactions in your input script to have a complete pairwise interaction model.

An alternative to using the `extra` keywords with the `read_data` command, is to use the `create_box` command to initialize the simulation box and all the various type limits you need via its `extra` keywords. Then use the `read_data` command
one or more times to populate the system with atoms, bonds, angles, etc, using the offset keyword if desired to alter types used in the various data files you read.

16.105.5 Format of a data file

The structure of the data file is important, though many settings and sections are optional or can come in any order. See the examples directory for sample data files for different problems.

The file will be read line by line, but there is a limit of 254 characters per line and characters beyond that limit will be ignored.

A data file has a header and a body. The header appears first. The first line of the header is always skipped; it typically contains a description of the file. Then lines are read one at a time. Lines can have a trailing comment starting with ‘#’ that is ignored. If the line is blank (only white-space after comment is deleted), it is skipped. If the line contains a header keyword, the corresponding value(s) is read from the line. If it does not contain a header keyword, the line begins the body of the file.

The body of the file contains zero or more sections. The first line of a section has only a keyword. This line can have a trailing comment starting with ‘#’ that is either ignored or can be used to check for a style match, as described below. The next line is skipped. The remaining lines of the section contain values. The number of lines depends on the section keyword as described below. Zero or more blank lines can be used between sections. Sections can appear in any order, with a few exceptions as noted below.

The keyword fix can be used one or more times. Each usage specifies a fix that will be used to process a specific portion of the data file. Any header line containing header-string and any section that is an exact match to section-string will be passed to the specified fix. See the fix property/atom command for an example of a fix that operates in this manner. The doc page for the fix defines the syntax of the header line(s) and section that it reads from the data file. Note that the header-string can be specified as NULL, in which case no header lines are passed to the fix. This means the fix can infer the length of its Section from standard header settings, such as the number of atoms. Also the section-string may be specified as NULL, and in that case the fix ID is used as section name.

The formatting of individual lines in the data file (indentation, spacing between words and numbers) is not important except that header and section keywords (e.g., atoms, xlo xhi, Masses, Bond Coefs) must be capitalized as shown and cannot have extra white-space between their words - e.g. two spaces or a tab between the 2 words in “xlo xhi” or the 2 words in “Bond Coefs”, is not valid.

16.105.6 Format of the header of a data file

These are the recognized header keywords. Header lines can come in any order. The value(s) are read from the beginning of the line. Thus the keyword atoms should be in a line like “1000 atoms”; the keyword ylo yhi should be in a line like “-10.0 10.0 ylo yhi”; the keyword x y z should be in a line like “0.0 5.0 6.0 x y z”. All these settings have a default value of 0, except the lo/hi box size defaults are -0.5 and 0.5. A line need only appear if the value is different than the default.

- atoms = # of atoms in system
- bonds = # of bonds in system
- angles = # of angles in system
- dihedrals = # of dihedrals in system
- impropers = # of impropers in system
- **atom types** = # of atom types in system
- **bond types** = # of bond types in system
- **angle types** = # of angle types in system
- **dihedral types** = # of dihedral types in system
- **improper types** = # of improper types in system
- **extra bond per atom** = leave space for this many new bonds per atom (deprecated, use extra/bond/per/atom keyword)
- **extra angle per atom** = leave space for this many new angles per atom (deprecated, use extra/angle/per/atom keyword)
- **extra dihedral per atom** = leave space for this many new dihedrals per atom (deprecated, use extra/dihedral/per/atom keyword)
- **extra improper per atom** = leave space for this many new impropers per atom (deprecated, use extra/improper/per/atom keyword)
- **extra special per atom** = leave space for this many new special bonds per atom (deprecated, use extra/special/per/atom keyword)
- **ellipsoids** = # of ellipsoids in system
- **lines** = # of line segments in system
- **triangles** = # of triangles in system
- **bodies** = # of bodies in system
- **xlo xhi** = simulation box boundaries in x dimension
- **ylo yhi** = simulation box boundaries in y dimension
- **zlo zhi** = simulation box boundaries in z dimension
- **xy xz yz** = simulation box tilt factors for triclinic system

The initial simulation box size is determined by the lo/hi settings. In any dimension, the system may be periodic or non-periodic; see the `boundary` command. When the simulation box is created it is also partitioned into a regular 3d grid of rectangular bricks, one per processor, based on the number of processors being used and the settings of the `processors` command. The partitioning can later be changed by the `balance` or `fix balance` commands.

If the `xy xz yz` line does not appear, LAMMPS will set up an axis-aligned (orthogonal) simulation box. If the line does appear, LAMMPS creates a non-orthogonal simulation domain shaped as a parallelepiped with triclinic symmetry. The parallelepiped has its “origin” at (xlo,ylo,zlo) and is defined by 3 edge vectors starting from the origin given by \( A = (xhi-xlo,0,0) \); \( B = (xy,yhi-ylo,0) \); \( C = (xz,yz,zhi-zlo) \). \( xy, xz, yz \) can be 0.0 or positive or negative values and are called “tilt factors” because they are the amount of displacement applied to faces of an originally orthogonal box to transform it into the parallelepiped.

By default, the tilt factors \((xy,xz,yz)\) can not skew the box more than half the distance of the corresponding parallel box length. For example, if \( xlo = 2 \) and \( xhi = 12 \), then the x box length is 10 and the xy tilt factor must be between -5 and 5. Similarly, both \( xz \) and \( yz \) must be between \(-(xhi-xlo)/2 \) and \( +(yhi-ylo)/2 \). Note that this is not a limitation, since if the maximum tilt factor is 5 (as in this example), then configurations with tilt = ..., -15, -5, 5, 15, 25, ... are all geometrically equivalent. If you wish to define a box with tilt factors that exceed these limits, you can use the `box tilt` command, with a setting of `large`; a setting of `small` is the default.

See the `Howto triclinic` page for a geometric description of triclinic boxes, as defined by LAMMPS, and how to transform these parameters to and from other commonly used triclinic representations.

When a triclinic system is used, the simulation domain should normally be periodic in the dimension that the tilt is applied to, which is given by the second dimension of the tilt factor (e.g. \( y \) for \( xy \) tilt). This is so that pairs of atoms...
interacting across that boundary will have one of them shifted by the tilt factor. Periodicity is set by the `boundary` command. For example, if the xy tilt factor is non-zero, then the y dimension should be periodic. Similarly, the z dimension should be periodic if xz or yz is non-zero. LAMMPS does not require this periodicity, but you may lose atoms if this is not the case.

Also note that if your simulation will tilt the box, e.g. via the `fix deform` command, the simulation box must be setup to be triclinic, even if the tilt factors are initially 0.0. You can also change an orthogonal box to a triclinic box or vice versa by using the `change box` command with its `ortho` and `triclinic` options.

For 2d simulations, the `zlo zhi` values should be set to bound the z coords for atoms that appear in the file; the default of -0.5 0.5 is valid if all z coords are 0.0. For 2d triclinic simulations, the xz and yz tilt factors must be 0.0.

If the system is periodic (in a dimension), then atom coordinates can be outside the bounds (in that dimension); they will be remapped (in a periodic sense) back inside the box. Note that if the `add` option is being used to add atoms to a simulation box that already exists, this periodic remapping will be performed using simulation box bounds that are the union of the existing box and the box boundaries in the new data file.

If the system is non-periodic (in a dimension), then an image flag for that direction has no meaning, since there cannot be periodic images without periodicity and the data file is therefore - technically speaking - invalid. This situation would happen when a data file was written with periodic boundaries and then read back for non-periodic boundaries. Accepting a non-zero image flag can lead to unexpected results for any operations and computations in LAMMPS that internally use unwrapped coordinates (for example computing the center of mass of a group of atoms). Thus all non-zero image flags for non-periodic dimensions will be reset to zero on reading the data file and LAMMPS will print a warning message, if that happens. This is equivalent to wrapping atoms individually back into the principal unit cell in that direction. This operation is equivalent to the behavior of the `change_box command` when used to change periodicity.

If those atoms with non-zero image flags are involved in bonded interactions, this reset can lead to undesired changes, when the image flag values differ between the atoms, i.e. the bonded interaction straddles domain boundaries. For example a bond can become stretched across the unit cell if one of its atoms is wrapped to one side of the cell and the second atom to the other. In those cases the data file needs to be pre-processed externally to become valid again. This can be done by first unwrapping coordinates and then wrapping entire molecules instead of individual atoms back into the principal simulation cell and finally expanding the cell dimensions in the non-periodic direction as needed, so that the image flag would be zero.

**Note:** If the system is non-periodic (in a dimension), then all atoms in the data file must have coordinates (in that dimension) that are “greater than or equal to” the lo value and “less than or equal to” the hi value. If the non-periodic dimension is of style “fixed” (see the `boundary` command), then the atom coords must be strictly “less than” the hi value, due to the way LAMMPS assign atoms to processors. Note that you should not make the lo/hi values radically smaller/larger than the extent of the atoms. For example, if your atoms extend from 0 to 50, you should not specify the box bounds as -10000 and 10000 unless you also use the `processors command`. This is because LAMMPS uses the specified box size to layout the 3d grid of processors. A huge (mostly empty) box will be sub-optimal for performance when using “fixed” boundary conditions (see the `boundary` command). When using “shrink-wrap” boundary conditions (see the `boundary` command), a huge (mostly empty) box may cause a parallel simulation to lose atoms when LAMMPS shrink-wraps the box around the atoms. The `read_data` command will generate an error in this case.

The “extra bond per atom” setting (angle, dihedral, improper) is only needed if new bonds (angles, dihedrals, impropers) will be added to the system when a simulation runs, e.g. by using the `fix bond/create` command. Using this header flag is deprecated; please use the `extra/bond/per/atom` keyword (and correspondingly for angles, dihedrals and impropers) in the `read_data` command instead. Either will pre-allocate space in LAMMPS data structures for storing the new bonds (angles, dihedrals, impropers).

The “extra special per atom” setting is typically only needed if new bonds/angles/etc will be added to the system, e.g. by using the `fix bond/create` command. Or if entire new molecules will be added to the system, e.g. by using the `fix deposit` or `fix pour` commands, which will have more special 1-2,1-3,1-4 neighbors than any other molecules defined in the data file. Using this header flag is deprecated; please use the `extra/special/per/atom` keyword instead. Using this
setting will pre-allocate space in the LAMMPS data structures for storing these neighbors. See the `special_bonds` and `molecule` doc pages for more discussion of 1-2,1-3,1-4 neighbors.

**Note:** All of the “extra” settings are only applied in the first data file read and when no simulation box has yet been created; as soon as the simulation box is created (and `read_data` implies that), these settings are locked and cannot be changed anymore. Please see the description of the `add` keyword above for reading multiple data files. If they appear in later data files, they are ignored.

The “ellipsoids” and “lines” and “triangles” and “bodies” settings are only used with `atom_style ellipsoid or line or tri or body` and specify how many of the atoms are finite-size ellipsoids or lines or triangles or bodies; the remainder are point particles. See the discussion of `ellipsoidflag` and the `Ellipsoids` section below. See the discussion of `lineflag` and the `Lines` section below. See the discussion of `triangleflag` and the `Triangles` section below. See the discussion of `bodyflag` and the `Bodies` section below.

**Note:** For `atom_style template`, the molecular topology (bonds, angles, etc) is contained in the molecule templates read-in by the `molecule` command. This means you cannot set the `bonds`, `angles`, etc header keywords in the data file, nor can you define `Bonds`, `Angles`, etc sections as discussed below. You can set the `bond types`, `angle types`, etc header keywords, though it is not necessary. If specified, they must match the maximum values defined in any of the template molecules.

### 16.105.7 Format of the body of a data file

These are the section keywords for the body of the file.

- **Atoms, Velocities, Masses, Ellipsoids, Lines, Triangles, Bodies** = atom-property sections
- **Bonds, Angles, Dihedrals, Impropers** = molecular topology sections
- **Pair Coeffs, PairIJ Coeffs, Bond Coeffs, Angle Coeffs, Dihedral Coeffs, Improper Coeffs** = force field sections
- **BondBond Coeffs, BondAngle Coeffs, MiddleBondTorsion Coeffs, EndBondTorsion Coeffs, AngleTorsion Coeffs, AngleAngleTorsion Coeffs, BondBond13 Coeffs, AngleAngle Coeffs** = class 2 force field sections

These keywords will check an appended comment for a match with the currently defined style:

- **Atoms, Pair Coeffs, PairIJ Coeffs, Bond Coeffs, Angle Coeffs, Dihedral Coeffs, Improper Coeffs**

For example, these lines:

```
Atoms # sphere
Pair Coeffs # lj/cut
```

will check if the currently-defined `atom_style` is `sphere`, and the current `pair_style` is `lj/cut`. If not, LAMMPS will issue a warning to indicate that the data file section likely does not contain the correct number or type of parameters expected for the currently-defined style.

Each section is listed below in alphabetic order. The format of each section is described including the number of lines it must contain and rules (if any) for where it can appear in the data file.

Any individual line in the various sections can have a trailing comment starting with “#” for annotation purposes. E.g. in the Atoms section:

```
10 1 17 -1.0 10.0 5.0 6.0  # salt ion
```

### 16.105. read_data command

931
Angle Coeffs section:

- one line per angle type
- line syntax: ID coeffs

```
ID = angle type (1-N)
coeffs = list of coeffs
```

- example:

```
6 70 108.5 0 0
```

The number and meaning of the coefficients are specific to the defined angle style. See the angle_style and angle_coeff commands for details. Coefficients can also be set via the angle_coeff command in the input script.

AngleAngle Coeffs section:

- one line per improper type
- line syntax: ID coeffs

```
ID = improper type (1-N)
coeffs = list of coeffs (see improper_coeff)
```

AngleTorsion Coeffs section:

- one line per dihedral type
- line syntax: ID coeffs

```
ID = dihedral type (1-N)
coeffs = list of coeffs (see dihedral_coeff)
```

Angles section:

- one line per angle
- line syntax: ID type atom1 atom2 atom3

```
ID = number of angle (1-Nangles)
type = angle type (1-Nangletype)
atom1,atom2,atom3 = IDs of 1st,2nd,3rd atom in angle
```

example:

```
2 2 17 29 430
```

The 3 atoms are ordered linearly within the angle. Thus the central atom (around which the angle is computed) is the atom2 in the list. E.g. H,O,H for a water molecule. The Angles section must appear after the Atoms section. All values in this section must be integers (1, not 1.0).

AngleTorsion Coeffs section:
• one line per dihedral type
• line syntax: ID coeffs

    ID = dihedral type (1-N)
    coeffs = list of coeffs (see dihedral_coeff)

**Atoms section:**

• one line per atom
• line syntax: depends on atom style

An *Atoms* section must appear in the data file if natoms > 0 in the header section. The atoms can be listed in any order. These are the line formats for each *atom style* in LAMMPS. As discussed below, each line can optionally have 3 flags (nx,ny,nz) appended to it, which indicate which image of a periodic simulation box the atom is in. These may be important to include for some kinds of analysis.

The per-atom values have these meanings and units, listed alphabetically:

• atom-ID = integer ID of atom
• atom-type = type of atom (1-Ntype)
• bodyflag = 1 for body particles, 0 for point particles
• bond_nt = bond NT factor for MESONT particles (?? units)
• buckling = buckling factor for MESONT particles (?? units)
- $ccN$ = chemical concentration for tDPD particles for each species (mole/volume units)
- $cradius$ = contact radius for SMD particles (distance units)
- $cs\_re,cs\_im$ = real/imaginary parts of wave packet coefficients
- $cv$ = heat capacity (need units) for SPH particles
- $density$ = density of particle (mass/distance^3 or mass/distance^2 or mass/distance units, depending on dimensionality of particle)
- $diameter$ = diameter of spherical atom (distance units)
- $esph$ = energy (need units) for SPH particles
- $edpd\_temp$ = temperature for eDPD particles (temperature units)
- $edpd\_cv$ = volumetric heat capacity for eDPD particles (energy/temperature/volume units)
- $ellipsoidflag$ = 1 for ellipsoidal particles, 0 for point particles
- $eradius$ = electron radius (or fixed-core radius)
- $etag$ = integer ID of electron that each wave packet belongs to
- $kradius$ = kernel radius for SMD particles (distance units)
- $lineflag$ = 1 for line segment particles, 0 for point or spherical particles
- $mass$ = mass of particle (mass units)
- $mlength$ = ?? length for MESONT particles (distance units)
- $molecule-ID$ = integer ID of molecule the atom belongs to
- $mradius$ = ?? radius for MESONT particles (distance units)
- $mux,muy,muz$ = components of dipole moment of atom (dipole units)
- $q$ = charge on atom (charge units)
- $rho$ = density (need units) for SPH particles
- $spin$ = electron spin (+1/-1), 0 = nuclei, 2 = fixed-core, 3 = pseudo-cores (i.e. ECP)
- $sp$ = magnitude of magnetic spin of atom (Bohr magnetons)
- $spx,spy,spz$ = components of magnetic spin of atom (unit vector)
- $template-atom$ = which atom within a template molecule the atom is
- $template-index$ = which molecule within the molecule template the atom is part of
- $theta$ = internal temperature of a DPD particle
- $triangleflag$ = 1 for triangular particles, 0 for point or spherical particles
- $volume$ = volume of Peridynamic particle (distance^3 units)
- $x,y,z$ = coordinates of atom (distance units)
- $x0,y0,z0$ = original (strain-free) coordinates of atom (distance units)

The units for these quantities depend on the unit style; see the $units$ command for details.

For 2d simulations specify $z$ as 0.0, or a value within the $zlo$ $zhi$ setting in the data file header.

The atom-ID is used to identify the atom throughout the simulation and in dump files. Normally, it is a unique value from 1 to Natoms for each atom. Unique values larger than Natoms can be used, but they will cause extra memory to be allocated on each processor, if an atom map array is used, but not if an atom map hash is used; see the $atom\_modify$
command for details. If an atom map is not used (e.g. an atomic system with no bonds), and you don’t care if unique atom IDs appear in dump files, then the atom-IDs can all be set to 0.

The molecule ID is a second identifier attached to an atom. Normally, it is a number from 1 to N, identifying which molecule the atom belongs to. It can be 0 if it is a non-bonded atom or if you don’t care to keep track of molecule assignments.

The diameter specifies the size of a finite-size spherical particle. It can be set to 0.0, which means that atom is a point particle.

The ellipsoidflag, lineflag, triangleflag, and bodyflag determine whether the particle is a finite-size ellipsoid or line or triangle or body of finite size, or whether the particle is a point particle. Additional attributes must be defined for each ellipsoid, line, triangle, or body in the corresponding Ellipsoids, Lines, Triangles, or Bodies section.

The template-index and template-atom are only defined used by atom_style template. In this case the molecule command is used to define a molecule template which contains one or more molecules (as separate files). If an atom belongs to one of those molecules, its template-index and template-atom are both set to positive integers; if not the values are both 0. The template-index is which molecule (1 to Nmols) the atom belongs to. The template-atom is which atom (1 to Natoms) within the molecule the atom is.

Some pair styles and fixes and computes that operate on finite-size particles allow for a mixture of finite-size and point particles. See the doc pages of individual commands for details.

For finite-size particles, the density is used in conjunction with the particle volume to set the mass of each particle as mass = density * volume. In this context, volume can be a 3d quantity (for spheres or ellipsoids), a 2d quantity (for triangles), or a 1d quantity (for line segments). If the volume is 0.0, meaning a point particle, then the density value is used as the mass. One exception is for the body atom style, in which case the mass of each particle (body or point particle) is specified explicitly. This is because the volume of the body is unknown.

Note that for 2d simulations of spheres, this command will treat them as spheres when converting density to mass. However, they can also be modeled as 2d discs (circles) if the set density/disc command is used to reset their mass after the read_data command is used. A disc keyword can also be used with time integration fixes, such as fix nve/sphere and fix nvt/sphere to time integrate their motion as 2d discs (not 3d spheres), by changing their moment of inertia.

For atom_style hybrid, following the 5 initial values (ID,type,x,y,z), specific values for each sub-style must be listed. The order of the sub-styles is the same as they were listed in the atom_style command. The specific values for each sub-style are those that are the 5 standard ones (ID,type,x,y,z). For example, for the “charge” sub-style, a “q” value would appear. For the “full” sub-style, a “molecule-ID” and “q” would appear. These are listed in the same order they appear as listed above. Thus if

```
atom_style hybrid charge sphere
```

were used in the input script, each atom line would have these fields:

```
atom-ID atom-type x y z q diameter density
```

Note that if a non-standard value is defined by multiple sub-styles, it only appears once in the atom line. E.g. the atom line for atom_style hybrid dipole full would list “q” only once, with the dipole sub-style fields; “q” does not appear with the full sub-style fields.

```
atom-ID atom-type x y z qmux muy myz molecule-ID
```

Atom lines specify the (x,y,z) coordinates of atoms. These can be inside or outside the simulation box. When the data file is read, LAMMPS wraps coordinates outside the box back into the box for dimensions that are periodic. As discussed above, if an atom is outside the box in a non-periodic dimension, it will be lost.

LAMMPS always stores atom coordinates as values which are inside the simulation box. It also stores 3 flags which indicate which image of the simulation box (in each dimension) the atom would be in if its coordinates were unwrapped across periodic boundaries. An image flag of 0 means the atom is still inside the box when unwrapped. A value of
2 means add 2 box lengths to get the unwrapped coordinate. A value of -1 means subtract 1 box length to get the unwrapped coordinate. LAMMPS updates these flags as atoms cross periodic boundaries during the simulation. The `dump` command can output atom coordinates in wrapped or unwrapped form, as well as the 3 image flags.

In the data file, atom lines (all lines or none of them) can optionally list 3 trailing integer values (nx,ny,nz), which are used to initialize the atom’s image flags. If nx,ny,nz values are not listed in the data file, LAMMPS initializes them to 0. Note that the image flags are immediately updated if an atom’s coordinates need to wrapped back into the simulation box.

It is only important to set image flags correctly in a data file if a simulation model relies on unwrapped coordinates for some calculation; otherwise they can be left unspecified. Examples of LAMMPS commands that use unwrapped coordinates internally are as follows:

- Atoms in a rigid body (see `fix rigid`, `fix rigid/small`) must have consistent image flags, so that when the atoms are unwrapped, they are near each other, i.e. as a single body.

- If the `replicate` command is used to generate a larger system, image flags must be consistent for bonded atoms when the bond crosses a periodic boundary. I.e. the values of the image flags should be different by 1 (in the appropriate dimension) for the two atoms in such a bond.

- If you plan to `dump` image flags and perform post-analysis that will unwrap atom coordinates, it may be important that a continued run (restarted from a data file) begins with image flags that are consistent with the previous run.

**Note:** If your system is an infinite periodic crystal with bonds then it is impossible to have fully consistent image flags. This is because some bonds will cross periodic boundaries and connect two atoms with the same image flag.

Atom velocities and other atom quantities not defined above are set to 0.0 when the Atoms section is read. Velocities can be set later by a `Velocities` section in the data file or by a `velocity` or `set` command in the input script.

**Bodies section:**

- one or more lines per body

- first line syntax: atom-ID Ninteger Ndouble

  \[
  \begin{align*}
  &\text{Ninteger = # of integer quantities for this particle} \\
  &\text{Ndouble = # of floating-point quantities for this particle}
  \end{align*}
  \]

- 0 or more integer lines with total of Ninteger values

- 0 or more double lines with total of Ndouble values

- example:

  \[
  \begin{align*}
  &\text{12 3 6} \\
  &2 3 2 \\
  &1.0 2.0 3.0 1.0 2.0 4.0
  \end{align*}
  \]

- example:

  \[
  \begin{align*}
  &\text{12 0 14} \\
  &1.0 2.0 3.0 1.0 2.0 4.0 1.0 \\
  &2.0 3.0 1.0 2.0 4.0 4.0 2.0
  \end{align*}
  \]

The `Bodies` section must appear if `atom_style body` is used and any atoms listed in the `Atoms` section have a bodyflag = 1. The number of bodies should be specified in the header section via the “bodies” keyword.
Each body can have a variable number of integer and/or floating-point values. The number and meaning of the values is defined by the body style, as described in the `Howto body ` doc page. The body style is given as an argument to the `atom_style body ` command.

The Ninteger and Ndouble values determine how many integer and floating-point values are specified for this particle. Ninteger and Ndouble can be as large as needed and can be different for every body. Integer values are then listed next on subsequent lines. Lines are read one at a time until Ninteger values are read. Floating-point values follow on subsequent lines. Again lines are read one at a time until Ndouble values are read. Note that if there are no values of a particular type, no lines appear for that type.

The `Bodies` section must appear after the `Atoms` section.

**Bond Coeffs** section:
- one line per bond type
- line syntax: ID coeffs
  
  \[
  \begin{align*}
  \text{ID} & = \text{bond type (1-N)} \\
  \text{coeffs} & = \text{list of coeffs}
  \end{align*}
  \]

  - example:

    \[
    \begin{align*}
    4 & 250 & 1.49
    \end{align*}
    \]

  The number and meaning of the coefficients are specific to the defined bond style. See the `bond_style` and `bond_coeff` commands for details. Coefficients can also be set via the `bond_coeff` command in the input script.

**BondAngle Coeffs** section:
- one line per angle type
- line syntax: ID coeffs
  
  \[
  \begin{align*}
  \text{ID} & = \text{angle type (1-N)} \\
  \text{coeffs} & = \text{list of coeffs (see class 2 section of angle_coeff)}
  \end{align*}
  \]

**BondBond Coeffs** section:
- one line per angle type
- line syntax: ID coeffs
  
  \[
  \begin{align*}
  \text{ID} & = \text{angle type (1-N)} \\
  \text{coeffs} & = \text{list of coeffs (see class 2 section of angle_coeff)}
  \end{align*}
  \]

**BondBond13 Coeffs** section:
- one line per dihedral type
- line syntax: ID coeffs
  
  \[
  \begin{align*}
  \text{ID} & = \text{dihedral type (1-N)} \\
  \text{coeffs} & = \text{list of coeffs (see class 2 section of dihedral_coeff)}
  \end{align*}
  \]

**Bonds** section:
• one line per bond

  - line syntax: ID type atom1 atom2

  | ID = bond number (1-Nbonds) |
  | type = bond type (1-Nbondtype) |
  | atom1,atom2 = IDs of 1st,2nd atom in bond |

  • example:

    12 3 17 29

The Bonds section must appear after the Atoms section. All values in this section must be integers (1, not 1.0).

**Dihedral Coeffs section:**

- one line per dihedral type

  - line syntax: ID coeffs

  | ID = dihedral type (1-N) |
  | coeffs = list of coeffs |

  • example:

    3 0.6 1 0 1

The number and meaning of the coefficients are specific to the defined dihedral style. See the dihedral_style and dihedral_coeff commands for details. Coefficients can also be set via the dihedral_coeff command in the input script.

**Dihedrals section:**

- one line per dihedral

  - line syntax: ID type atom1 atom2 atom3 atom4

  | ID = number of dihedral (1-Ndihedrals) |
  | type = dihedral type (1-Ndihedraltype) |
  | atom1,atom2,atom3,atom4 = IDs of 1st,2nd,3rd,4th atom in dihedral |

  • example:

    12 4 17 29 30 21

The 4 atoms are ordered linearly within the dihedral. The Dihedrals section must appear after the Atoms section. All values in this section must be integers (1, not 1.0).

**Ellipsoids section:**

- one line per ellipsoid

  - line syntax: atom-ID shapex shapey shapez quatw quati quatj quatk

  | atom-ID = ID of atom which is an ellipsoid |
  | shapex,shapey,shapez = 3 diameters of ellipsoid (distance units) |
  | quatw,quati,quatj,quatk = quaternion components for orientation of atom |

938 Chapter 16. Commands
• example:

```
12 1 1 1 0 0 0
```

The *Ellipsoids* section must appear if *atom_style ellipsoid* is used and any atoms are listed in the *Atoms* section with an ellipsoidflag = 1. The number of ellipsoids should be specified in the header section via the “ellipsoids” keyword.

The 3 shape values specify the 3 diameters or aspect ratios of a finite-size ellipsoidal particle, when it is oriented along the 3 coordinate axes. They must all be non-zero values.

The values *quatw*, *quati*, *quatj*, and *quatk* set the orientation of the atom as a quaternion (4-vector). Note that the shape attributes specify the aspect ratios of an ellipsoidal particle, which is oriented by default with its x-axis along the simulation box’s x-axis, and similarly for y and z. If this body is rotated (via the right-hand rule) by an angle theta around a unit vector (a,b,c), then the quaternion that represents its new orientation is given by (cos(theta/2), a*sin(theta/2), b*sin(theta/2), c*sin(theta/2)). These 4 components are *quatw*, *quati*, *quatj*, and *quatk* as specified above. LAMMPS normalizes each atom’s quaternion in case (a,b,c) is not specified as a unit vector.

The *Ellipsoids* section must appear after the *Atoms* section.

---

**EndBondTorsion Coeffs** section:

- one line per dihedral type
- line syntax: ID coeffs

  ID = dihedral type (1-N)
  coeffs = list of coeffs (see class 2 section of *dihedral_coeff*)

---

**Improper Coeffs** section:

- one line per improper type
- line syntax: ID coeffs

  ID = improper type (1-N)
  coeffs = list of coeffs

- example:

```
2 20 0.0548311
```

The number and meaning of the coefficients are specific to the defined improper style. See the *improper_style* and *improper_coeff* commands for details. Coefficients can also be set via the *improper_coeff* command in the input script.

---

**Improper** section:

- one line per improper
- line syntax: ID type atom1 atom2 atom3 atom4

  ID = number of improper (1-Nimpropers)
  type = improper type (1-Nimproptype)
  atom1,atom2,atom3,atom4 = IDs of 1st,2nd,3rd,4th atom in improper

- example:
The ordering of the 4 atoms determines the definition of the improper angle used in the formula for each improper style. See the doc pages for individual styles for details.

The Improper section must appear after the Atoms section. All values in this section must be integers (1, not 1.0).

### Lines section:
- one line per line segment
- line syntax: atom-ID x1 y1 x2 y2

<table>
<thead>
<tr>
<th>atom-ID</th>
<th>x1, y1</th>
<th>x2, y2</th>
</tr>
</thead>
<tbody>
<tr>
<td>12</td>
<td>1.0</td>
<td>0.0</td>
</tr>
</tbody>
</table>

The Lines section must appear if `atom_style line` is used and any atoms are listed in the Atoms section with a lineflag = 1. The number of lines should be specified in the header section via the “lines” keyword.

The 2 end points are the end points of the line segment. The ordering of the 2 points should be such that using a right-hand rule to cross the line segment with a unit vector in the +z direction, gives an “outward” normal vector perpendicular to the line segment. I.e. normal = (c2-c1) x (0,0,1). This orientation may be important for defining some interactions.

The Lines section must appear after the Atoms section.

### Masses section:
- one line per atom type
- line syntax: ID mass

<table>
<thead>
<tr>
<th>ID</th>
<th>mass</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>1.01</td>
</tr>
</tbody>
</table>

This defines the mass of each atom type. This can also be set via the `mass` command in the input script. This section cannot be used for atom styles that define a mass for individual atoms - e.g. `atom_style sphere`.

### MiddleBondTorsion Coeffs section:
- one line per dihedral type
- line syntax: ID coeffs

<table>
<thead>
<tr>
<th>ID</th>
<th>coeffs</th>
</tr>
</thead>
<tbody>
<tr>
<td>7</td>
<td>c1, c2, c3</td>
</tr>
</tbody>
</table>

This section is required if the `atom_style line` style is used and at least one atom has a lineflag = 1. The number of dihedrals should be specified in the header section via the “dihedrals” keyword.

The ordering of the dihedrals should be such that attending to the line segment, the dihedrals are defined in the clockwise sense.

This section cannot be used for atom styles that define a dihedral for individual atoms - e.g. `atom_style sphere` or `atom_style rigid`.
**Pair Coeffs** section:

- one line per atom type
- line syntax: ID coeffs

<table>
<thead>
<tr>
<th>ID = atom type (1-N)</th>
</tr>
</thead>
<tbody>
<tr>
<td>coeffs = list of coeffs</td>
</tr>
</tbody>
</table>

- example:

```
3 0.022 2.35197 0.022 2.35197
```

The number and meaning of the coefficients are specific to the defined pair style. See the `pair_style` and `pair_coeff` commands for details. Since pair coefficients for types I != J are not specified, these will be generated automatically by the pair style’s mixing rule. See the individual pair_style doc pages and the `pair_modify mix` command for details. Pair coefficients can also be set via the `pair_coeff` command in the input script.

**PairIJ Coeffs** section:

- one line per pair of atom types for all I,J with I <= J
- line syntax: ID1 ID2 coeffs

<table>
<thead>
<tr>
<th>ID1 = atom type I = 1-N</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID2 = atom type J = I-N, with I &lt;= J</td>
</tr>
<tr>
<td>coeffs = list of coeffs</td>
</tr>
</tbody>
</table>

- examples:

```
3 3 0.022 2.35197 0.022 2.35197
3 5 0.022 2.35197 0.022 2.35197
```

This section must have N*(N+1)/2 lines where N = # of atom types. The number and meaning of the coefficients are specific to the defined pair style. See the `pair_style` and `pair_coeff` commands for details. Since pair coefficients for types I != J are all specified, these values will turn off the default mixing rule defined by the pair style. See the individual pair_style doc pages and the `pair_modify mix` command for details. Pair coefficients can also be set via the `pair_coeff` command in the input script.

**Triangles** section:

- one line per triangle
- line syntax: atom-ID x1 y1 z1 x2 y2 z2 x3 y3 z3

<table>
<thead>
<tr>
<th>atom-ID = ID of atom which is a line segment</th>
</tr>
</thead>
<tbody>
<tr>
<td>x1,y1,z1 = 1st corner point</td>
</tr>
<tr>
<td>x2,y2,z2 = 2nd corner point</td>
</tr>
<tr>
<td>x3,y3,z3 = 3rd corner point</td>
</tr>
</tbody>
</table>

- example:
The *Triangles* section must appear if *atom_style tri* is used and any atoms are listed in the *Atoms* section with a triangleflag = 1. The number of lines should be specified in the header section via the “triangles” keyword.

The 3 corner points are the corner points of the triangle. The ordering of the 3 points should be such that using a right-hand rule to go from point1 to point2 to point3 gives an “outward” normal vector to the face of the triangle. I.e. normal = (c2-c1) x (c3-c1). This orientation may be important for defining some interactions.

The *Triangles* section must appear after the *Atoms* section.

**Velocities section:**

- one line per atom
- line syntax: depends on atom style

<table>
<thead>
<tr>
<th>all styles except those listed</th>
<th>atom-ID vx vy vz</th>
</tr>
</thead>
<tbody>
<tr>
<td>electron</td>
<td>atom-ID vx vy vz ervel</td>
</tr>
<tr>
<td>ellipsoid</td>
<td>atom-ID vx vy vz lx ly lz</td>
</tr>
<tr>
<td>sphere</td>
<td>atom-ID vx vy vz wx wy wz</td>
</tr>
<tr>
<td>hybrid</td>
<td>atom-ID vx vy vz sub-style1 sub-style2 …</td>
</tr>
</tbody>
</table>

where the keywords have these meanings:

vx, vy, vz = translational velocity of atom
lx, ly, lz = angular momentum of aspherical atom
wx, wy, wz = angular velocity of spherical atom
ervel = electron radial velocity (0 for fixed-core):ul

The velocity lines can appear in any order. This section can only be used after an *Atoms* section. This is because the *Atoms* section must have assigned a unique atom ID to each atom so that velocities can be assigned to them.

Vx, vy, vz, and ervel are in units of velocity. Lx, ly, lz are in units of angular momentum (distance-velocity-mass). Wx, Wy, Wz are in units of angular velocity (radians/time).

For *atom_style hybrid*, following the 4 initial values (ID,vx,vy,vz), specific values for each sub-style must be listed. The order of the sub-styles is the same as they were listed in the *atom_style* command. The sub-style specific values are those that are not the 5 standard ones (ID,vx,vy,vz). For example, for the “sphere” sub-style, “wx”, “wy”, “wz” values would appear. These are listed in the same order they appear as listed above. Thus if

```plaintext
atom_style hybrid electron sphere
```

were used in the input script, each velocity line would have these fields:

```plaintext
atom-ID vx vy vz ervel wx wy wz
```

Translational velocities can also be set by the *velocity* command in the input script.
16.105.8 Restrictions

To read gzipped data files, you must compile LAMMPS with the -DLAMMPS_GZIP option. See the Build settings doc page for details.

16.105.9 Related commands

read_dump, read_restart, create_atoms, write_data

16.105.10 Default

The default for all the extra keywords is 0.

16.106 read_dump command

16.106.1 Syntax

```
read_dump file Nstep field1 field2 ... keyword values ...
```

- file = name of dump file to read
- Nstep = snapshot timestep to read from file
- one or more fields may be appended
  - field = x or y or z or vx or vy or vz or q or ix or iy or iz or fx or fy or fz
    - x,y,z = atom coordinates
    - vx,vy,vz = velocity components
    - q = charge
    - ix,iy,iz = image flags in each dimension
    - fx, fy, fz = force components
- zero or more keyword/value pairs may be appended
- keyword = nfile or box or replace or purge or trim or add or label or scaled or wrapped or format
  - nfile value = Nfiles = how many parallel dump files exist
  - box value = yes or no = replace simulation box with dump box
  - replace value = yes or no = overwrite atoms with dump atoms
  - purge value = yes or no = delete all atoms before adding dump atoms
  - trim value = yes or no = trim atoms not in dump snapshot
  - add value = yes or keep or no = add new dump atoms to system
  - label value = field column
    - field = one of the listed fields or id or type
    - column = label on corresponding column in dump file
  - scaled value = yes or no = coords in dump file are scaled/unscaled
  - wrapped value = yes or no = coords in dump file are wrapped/unwrapped
  - format values = format of dump file, must be last keyword if used
    - native = native LAMMPS dump file
    - xyz = XYZ file
    - adios [timeout value] = dump file written by the dump adios command
    - timeout = specify waiting time for the arrival of the timestep when running concurrently.
The value is a float number and is interpreted in seconds.

molfile style path = VMD molfile plugin interface
style = dcd or xyz or others supported by molfile plugins
path = optional path for location of molfile plugins

### 16.106.2 Examples

- `read_dump` dump.file 5000 x y z
- `read_dump` dump.xyz 5 x y z box no format xyz
- `read_dump` dump.xyz 10 x y z box no format molfile xyz "../plugins"
- `read_dump` dump.dcd 0 x y z box yes format molfile dcd
- `read_dump` dump.file 1000 x y z vx vy vz box yes format molfile lammpstrj /usr/local/lib/
  ...vmd/plugins/LINUXAMD64/plugins/molfile
- `read_dump` dump.dcd 0 x y z box yes format molfile dcd
- `read_dump` dump.xyz 10 x y z box no format molfile xyz ..:/plugins
- `read_dump` dump.dcd 0 x y z box yes format molfile dcd
- `read_dump` dump.file 1000 x y z vx vy vz box yes format molfile lammpstrj /usr/local/lib/vmd/
  ...plugins/LINUXAMD64/plugins/molfile
- `read_dump` dump.bp 5000 x y z vx vy vz format adios
- `read_dump` dump.bp 5000 x y z vx vy vz format adios timeout 60.0

### 16.106.3 Description

Read atom information from a dump file to overwrite the current atom coordinates, and optionally the atom velocities and image flags and the simulation box dimensions. This is useful for restarting a run from a particular snapshot in a dump file. See the `read_restart` and `read_data` commands for alternative methods to do this. Also see the `rerun` command for a means of reading multiple snapshots from a dump file.

Note that a simulation box must already be defined before using the `read_dump` command. This can be done by the `create_box`, `read_data`, or `read_restart` commands. The `read_dump` command can reset the simulation box dimensions, as explained below.

Also note that reading per-atom information from a dump snapshot is limited to the atom coordinates, velocities and image flags, as explained below. Other atom properties, which may be necessary to run a valid simulation, such as atom charge, or bond topology information for a molecular system, are not read from (or even contained in) dump files. Thus this auxiliary information should be defined in the usual way, e.g. in a data file read in by a `read_data` command, before using the `read_dump` command, or by the `set` command, after the dump snapshot is read.

If the dump filename specified as `file` ends with ".gz", the dump file is read in gzipped format.

You can read dump files that were written (in parallel) to multiple files via the “%” wild-card character in the dump file name. If any specified dump file name contains a “%”, they must all contain it. See the `dump` command for details. The “%” wild-card character is only supported by the `native` format for dump files, described next.

If reading parallel dump files, you must also use the `nfile` keyword to tell LAMMPS how many parallel files exist, via its specified `Nfiles` value.

The format of the dump file is selected through the `format` keyword. If specified, it must be the last keyword used, since all remaining arguments are passed on to the dump reader. The `native` format is for native LAMMPS dump files, written with a `dump atom` or `dump custom` command. The `xyz` format is for generic XYZ formatted dump files. These formats take no additional values.
The `molfile` format supports reading data through using the VMD molfile plugin interface. This dump reader format is only available, if the MOLFILE package has been installed when compiling LAMMPS.

The `molfile` format takes one or two additional values. The `style` value determines the file format to be used and can be any format that the molfile plugins support, such as DCD or XYZ. Note that DCD dump files can be written by LAMMPS via the `dump dcd` command. The `path` value specifies a list of directories which LAMMPS will search for the molfile plugins appropriate to the specified `style`. The syntax of the `path` value is like other search paths: it can contain multiple directories separated by a colon (or semi-colon on windows). The `path` keyword is optional and defaults to “.”, i.e. the current directory.

The `adios` format supports reading data that was written by the `dump adios` command. The entire dump is read in parallel across all the processes, dividing the atoms evenly among the processes. The number of writers that has written the dump file does not matter. Using the adios style for dump and read_dump is a convenient way to dump all atoms from `N` writers and read it back by `M` readers. If one is running two LAMMPS instances concurrently where one dumps data and the other is reading it with the rerun command, the timeout option can be specified to wait on the reader side for the arrival of the requested step.

Support for other dump format readers may be added in the future.

Global information is first read from the dump file, namely timestep and box information.

The dump file is scanned for a snapshot with a timestamp that matches the specified `Nstep`. This means the LAMMPS timestep the dump file snapshot was written on for the native or adios formats.

The list of timestamps available in an adios .bp file is stored in the variable `ntimestep`:

```
$ bpls dump.bp -d ntimestep
uint64_t ntimestep 5*scalar
  (0)  0  50 100 150 200
```

Note that the `xyz` and `molfile` formats do not store the timestep. For these formats, timesteps are numbered logically, in a sequential manner, starting from 0. Thus to access the 10th snapshot in an `xyz` or `molfile` formatted dump file, use `Nstep = 9`.

The dimensions of the simulation box for the selected snapshot are also read; see the `box` keyword discussion below. For the native format, an error is generated if the snapshot is for a triclinic box and the current simulation box is orthogonal or vice versa. A warning will be generated if the snapshot box boundary conditions (periodic, shrink-wrapped, etc) do not match the current simulation boundary conditions, but the boundary condition information in the snapshot is otherwise ignored. See the “boundary” command for more details. The adios reader does the same as the native format reader.

For the `xyz` format, no information about the box is available, so you must set the `box` flag to `no`. See details below.

For the `molfile` format, reading simulation box information is typically supported, but the location of the simulation box origin is lost and no explicit information about periodicity or orthogonal/triclinic box shape is available. The MOLFILE package makes a best effort to guess based on heuristics, but this may not always work perfectly.

Per-atom information from the dump file snapshot is then read from the dump file snapshot. This corresponds to the specified `fields` listed in the read_dump command. It is an error to specify a z-dimension field, namely `z`, `vz`, or `iz`, for a 2d simulation.

For dump files in native format, each column of per-atom data has a text label listed in the file. A matching label for each field must appear, e.g. the label “vy” for the field `vy`. For the `x`, `y`, `z` fields any of the following labels are considered a match:

```
x, xs, xu, xsu for field x
y, ys, yu, ysu for field y
z, zs, zu, zsu for field z
```

16.106. read_dump command
The meaning of xs (scaled), xu (unwrapped), and xsu (scaled and unwrapped) is explained on the dump command documentation page. These labels are searched for in the list of column labels in the dump file, in order, until a match is found.

The dump file must also contain atom IDs, with a column label of “id”.

If the add keyword is specified with a value of yes or keep, as discussed below, the dump file must contain atom types, with a column label of “type”.

If a column label you want to read from the dump file is not a match to a specified field, the label keyword can be used to specify the specific column label from the dump file to associate with that field. An example is if a time-averaged coordinate is written to the dump file via the fix ave/atom command. The column will then have a label corresponding to the fix-ID rather than “x” or “xs”. The label keyword can also be used to specify new column labels for fields id and type.

For dump files in xyz format, only the x, y, and z fields are supported. The dump file does not store atom IDs, so these are assigned consecutively to the atoms as they appear in the dump file, starting from 1. Thus you should insure that order of atoms is consistent from snapshot to snapshot in the XYZ dump file. See the dump_modify sort command if the XYZ dump file was written by LAMMPS.

For dump files in molfile format, the x, y, z, vx, vy, and vz fields can be specified. However, not all molfile formats store velocities, or their respective plugins may not support reading of velocities. The molfile dump files do not store atom IDs, so these are assigned consecutively to the atoms as they appear in the dump file, starting from 1. Thus you should insure that order of atoms are consistent from snapshot to snapshot in the molfile dump file. See the dump_modify sort command if the dump file was written by LAMMPS.

The adios format supports all fields that the native format supports except for the q charge field. The list of fields stored in an adios .bp file is recorded in the attributes columns (array of short strings) and columnsstr (space-separated single string).

```
$ bpls -la dump.bp column*
string columns attr = {"id", "type", "x", "y", "z", "vx", "vy", "vz"}
string columnsstr attr = "id type x y z vx vy vz "
```

Information from the dump file snapshot is used to overwrite or replace properties of the current system. There are various options for how this is done, determined by the specified fields and optional keywords.

The timestep of the snapshot becomes the current timestep for the simulation. See the reset_timestep command if you wish to change this after the dump snapshot is read.

If the box keyword is specified with a yes value, then the current simulation box dimensions are replaced by the dump snapshot box dimensions. If the box keyword is specified with a no value, the current simulation box is unchanged.

If the purge keyword is specified with a yes value, then all current atoms in the system are deleted before any of the operations invoked by the replace, trim, or add keywords take place.

If the replace keyword is specified with a yes value, then atoms with IDs that are in both the current system and the dump snapshot have their properties overwritten by field values. If the replace keyword is specified with a no value, atoms with IDs that are in both the current system and the dump snapshot are not modified.

If the trim keyword is specified with a yes value, then atoms with IDs that are in the current system but not in the dump snapshot are deleted. These atoms are unaffected if the trim keyword is specified with a no value.

If the add keyword is specified with a no value (default), then dump file atoms with IDs that are not in the current system are not added to the system. They are simply ignored.

If a yes value is specified, the atoms with new IDs are added to the system but their atom IDs are not preserved. Instead, after all the atoms are added, new IDs are assigned to them in the same manner as is described for the create_atoms command. Basically the largest existing atom ID in the system is identified, and all the added atoms are assigned IDs that consecutively follow the largest ID.
If a *keep* value is specified, the atoms with new IDs are added to the system and their atom IDs are preserved. This may lead to non-contiguous IDs for the combined system.

Note that atoms added via the *add* keyword will only have the attributes read from the dump file due to the *field* arguments. For example, if *x* or *y* or *z* or *q* is not specified as a field, a value of 0.0 is used for added atoms. Added atoms must have an atom type, so this value must appear in the dump file.

Any other attributes (e.g. charge or particle diameter for spherical particles) will be set to default values, the same as if the *create_atoms* command were used.

Atom coordinates read from the dump file are first converted into unscaled coordinates, relative to the box dimensions of the snapshot. These coordinates are then be assigned to an existing or new atom in the current simulation. The coordinates will then be remapped to the simulation box, whether it is the original box or the dump snapshot box. If periodic boundary conditions apply, this means the atom will be remapped back into the simulation box if necessary. If shrink-wrap boundary conditions apply, the new coordinates may change the simulation box dimensions. If fixed boundary conditions apply, the atom will be lost if it is outside the simulation box.

For *native* format dump files, the 3 *xyz* image flags for an atom in the dump file are set to the corresponding values appearing in the dump file if the *ix*, *iy*, *iz* fields are specified. If not specified, the image flags for replaced atoms are not changed and image flags for new atoms are set to default values. If coordinates read from the dump file are in unwrapped format (e.g. *xu*) then the image flags for read-in atoms are also set to default values. The remapping procedure described in the previous paragraph will then change images flags for all atoms (old and new) if periodic boundary conditions are applied to remap an atom back into the simulation box.

**Note:** If you get a warning about inconsistent image flags after reading in a dump snapshot, it means one or more pairs of bonded atoms now have inconsistent image flags. As discussed on the *Errors common* page this may or may not cause problems for subsequent simulations. One way this can happen is if you read image flag fields from the dump file but do not also use the dump file box parameters.

LAMMPS knows how to compute unscaled and remapped coordinates for the snapshot column labels discussed above, e.g. *x*, *xs*, *xu*, *xsu*. If another column label is assigned to the *x* or *y* or *z* field via the *label* keyword, e.g. for coordinates output by the *fix ave/atom* command, then LAMMPS needs to know whether the coordinate information in the dump file is scaled and/or wrapped. This can be set via the *scaled* and *wrapped* keywords. Note that the value of the *scaled* and *wrapped* keywords is ignored for fields *x* or *y* or *z* if the *label* keyword is not used to assign a column label to that field.

The scaled/unscaled and wrapped/unwrapped setting must be identical for any of the *x*, *y*, *z* fields that are specified. Thus you cannot read *xs* and *yu* from the dump file. Also, if the dump file coordinates are scaled and the simulation box is triclinic, then all 3 of the *x*, *y*, *z* fields must be specified, since they are all needed to generate absolute, unscaled coordinates.

### 16.10.6.4 Restrictions

To read gzipped dump files, you must compile LAMMPS with the -DLAMMPS_GZIP option. See the *Build settings* doc page for details.

The *molfile* dump file formats are part of the MOLFILE package. They are only enabled if LAMMPS was built with that packages. See the *Build package* page for more info.

To write and read adios .bp files, you must compile LAMMPS with the ADIOS package.
16.106.5 Related commands

dump, dump molfile, dump adios, read_data, read_restart, rerun

16.106.6 Default

The option defaults are box = yes, replace = yes, purge = no, trim = no, add = no, scaled = no, wrapped = yes, and
format = native.

16.107 read_restart command

16.107.1 Syntax

```
read_restart file flag
```

- file = name of binary restart file to read in

16.107.2 Examples

```
read_restart save.10000
read_restart restart.*
read_restart restart.*.mpiio
```

16.107.3 Description

Read in a previously saved system configuration from a restart file. This allows continuation of a previous run. Details
about what information is stored (and not stored) in a restart file is given below. Basically this operation will re-create
the simulation box with all its atoms and their attributes as well as some related global settings, at the point in time it
was written to the restart file by a previous simulation. The simulation box will be partitioned into a regular 3d grid of
rectangular bricks, one per processor, based on the number of processors in the current simulation and the settings of
the processors command. The partitioning can later be changed by the balance or fix balance commands.

Restart files are saved in binary format to enable exact restarts, meaning that the trajectories of a restarted run will
precisely match those produced by the original run had it continued on.

The binary restart file format was not designed with backward, forward, or cross-platform compatibility in mind, so
the files are only expected to be read correctly by the same LAMMPS executable on the same platform. Changes to
the architecture, compilation settings, or LAMMPS version can render a restart file unreadable or it may read the data
incorrectly. If you want a more portable format, you can use the data file format as created by the write_data command.
Binary restart files can also be converted into a data file from the command line by the LAMMPS executable that wrote
them using the -restart2data command line flag.

Several things can prevent exact restarts due to round-off effects, in which case the trajectories in the 2 runs will slowly
diverge. These include running on a different number of processors or changing certain settings such as those set by
the newton or processors commands. LAMMPS will issue a warning in these cases.

Certain fixes will not restart exactly, though they should provide statistically similar results. These include fix shake
and fix langevin.

Certain pair styles will not restart exactly, though they should provide statistically similar results. This is because the
forces they compute depend on atom velocities, which are used at half-step values every timestep when forces are
computed. When a run restarts, forces are initially evaluated with a full-step velocity, which is different than if the run had continued. These pair styles include granular pair styles, pair dpd, and pair lubricate.

If a restarted run is immediately different than the run which produced the restart file, it could be a LAMMPS bug, so consider reporting it if you think the behavior is a bug.

Because restart files are binary, they may not be portable to other machines. In this case, you can use the -restart command-line switch to convert a restart file to a data file.

Similar to how restart files are written (see the write_restart and restart commands), the restart filename can contain two wild-card characters. If a "*" appears in the filename, the directory is searched for all filenames that match the pattern where "*" is replaced with a timestep value. The file with the largest timestep value is read in. Thus, this effectively means, read the latest restart file. It’s useful if you want your script to continue a run from where it left off. See the run command and its "upto" option for how to specify the run command so it does not need to be changed either.

If a "%" character appears in the restart filename, LAMMPS expects a set of multiple files to exist. The restart and write_restart commands explain how such sets are created. Read_restart will first read a filename where "%" is replaced by "base". This file tells LAMMPS how many processors created the set and how many files are in it. Read_restart then reads the additional files. For example, if the restart file was specified as save.% when it was written, then read_restart reads the files save.base, save.0, save.1, ... save.P-1, where P is the number of processors that created the restart file.

Note that P could be the total number of processors in the previous simulation, or some subset of those processors, if the fileper or nfile options were used when the restart file was written; see the restart and write_restart commands for details. The processors in the current LAMMPS simulation share the work of reading these files; each reads a roughly equal subset of the files. The number of processors which created the set can be different the number of processors in the current LAMMPS simulation. This can be a fast mode of input on parallel machines that support parallel I/O.

A restart file can also be read in parallel as one large binary file via the MPI-IO library, assuming it was also written with MPI-IO. MPI-IO is part of the MPI standard for versions 2.0 and above. Using MPI-IO requires two steps. First, build LAMMPS with its MPIIO package installed, e.g.

```
make yes-mpiio  # installs the MPIIO package
make mpi        # build LAMMPS for your platform
```

Second, use a restart filename which contains "%.mpiio". Note that it does not have to end in "%.mpiio", just contain those characters. Unlike MPI-IO dump files, a particular restart file must be both written and read using MPI-IO.

Here is the list of information included in a restart file, which means these quantities do not need to be re-specified in the input script that reads the restart file, though you can redefine many of these settings after the restart file is read.

- units
- newton bond (see discussion of newton command below)
- atom style and atom_modify settings id, map, sort
- comm style and comm_modify settings mode, cutoff, vel
- timestep
- simulation box size and shape and boundary settings
- atom group definitions
- per-type atom settings such as mass
- per-atom attributes including their group assignments and molecular topology attributes (bonds, angles, etc)
- force field styles (pair, bond, angle, etc)
- force field coefficients (pair, bond, angle, etc) in some cases (see below)
• *pair_modify* settings, except the compute option

• *special_bonds* settings

Here is a list of information not stored in a restart file, which means you must re-issue these commands in your input script, after reading the restart file.

• *newton pair* (see discussion of newton command below)

• *fix* commands (see below)

• *compute* commands (see below)

• *variable* commands

• *region* commands

• *neighbor list* criteria including *neigh_modify* settings

• *kspace_style* and *kspace_modify* settings

• info for *thermodynamic*, *dump*, or *restart* output

The *newton* command has two settings, one for pairwise interactions, the other for bonded. Both settings are stored in the restart file. For the bond setting, the value in the file will overwrite the current value (at the time the read_restart command is issued) and warn if the two values are not the same and the current value is not the default. For the pair setting, the value in the file will not overwrite the current value (so that you can override the previous run’s value), but a warning is issued if the two values are not the same and the current value is not the default.

Note that some force field styles (pair, bond, angle, etc) do not store their coefficient info in restart files. Typically these are many-body or tabulated potentials which read their parameters from separate files. In these cases you will need to re-specify the *pair_coeff*, *bond_coeff*, etc commands in your restart input script. The doc pages for individual force field styles mention if this is the case. This is also true of *pair_style hybrid* (bond hybrid, angle hybrid, etc) commands; they do not store coefficient info.

As indicated in the above list, the *fixes* used for a simulation are not stored in the restart file. This means the new input script should specify all fixes it will use. However, note that some fixes store an internal “state” which is written to the restart file. This allows the fix to continue on with its calculations in a restarted simulation. To re-enable such a fix, the fix command in the new input script must be of the same style and use the same fix-ID as was used in the input script that wrote the restart file.

If a match is found, LAMMPS prints a message indicating that the fix is being re-enabled. If no match is found before the first run or minimization is performed by the new script, the “state” information for the saved fix is discarded. At the time the discard occurs, LAMMPS will also print a list of fixes for which the information is being discarded. See the doc pages for individual fixes for info on which ones can be restarted in this manner. Note that fixes which are created internally by other LAMMPS commands (computes, fixes, etc) will have style names which are all-capitalized, and IDs which are generated internally.

Likewise, the *computes* used for a simulation are not stored in the restart file. This means the new input script should specify all computes it will use. However, some computes create a fix internally to store “state” information that persists from timestep to timestep. An example is the *compute msd* command which uses a fix to store a reference coordinate for each atom, so that a displacement can be calculated at any later time. If the compute command in the new input script uses the same compute-ID and group-ID as was used in the input script that wrote the restart file, then it will create the same fix in the restarted run. This means the re-created fix will be re-enabled with the stored state information as described in the previous paragraph, so that the compute can continue its calculations in a consistent manner.

**Note:** There are a handful of commands which can be used before or between runs which may require a system initialization. Examples include the “balance”, “displace_atoms”, “delete_atoms”, “set” (some options), and “velocity” (some options) commands. This is because they can migrate atoms to new processors. Thus they will also discard unused “state” information from fixes. You will know the discard has occurred because a list of discarded fixes will be
printed to the screen and log file, as explained above. This means that if you wish to retain that info in a restarted run, you must re-specify the relevant fixes and computes (which create fixes) before those commands are used.

Some pair styles, like the granular pair styles, also use a fix to store “state” information that persists from timestep to timestep. In the case of granular potentials, it is contact information between pairs of touching particles. This info will also be re-enabled in the restart script, assuming you re-use the same granular pair style.

LAMMPS allows bond interactions (angle, etc) to be turned off or deleted in various ways, which can affect how their info is stored in a restart file.

If bonds (angles, etc) have been turned off by the fix shake or delete_bonds command, their info will be written to a restart file as if they are turned on. This means they will need to be turned off again in a new run after the restart file is read.

Bonds that are broken (e.g. by a bond-breaking potential) are written to the restart file as broken bonds with a type of 0. Thus these bonds will still be broken when the restart file is read.

Bonds that have been broken by the fix bond/break command have disappeared from the system. No information about these bonds is written to the restart file.

### 16.107.4 Restrictions

To write and read restart files in parallel with MPI-IO, the MPIIO package must be installed.

### 16.108 region command

#### 16.108.1 Syntax

```
region ID style args keyword arg ...
```

- ID = user-assigned name for the region
- style = `delete` or `block` or `cone` or `cylinder` or `ellipsoid` or `plane` or `prism` or `sphere` or `union` or `intersect`
  - `delete` = no args
  - `block` args = `xlo xhi ylo yhi zlo zhi`
    - `xlo,xhi,ylo,yhi,zlo,zhi` = bounds of block in all dimensions (distance units)
  - `cone` args = `dim c1 c2 radlo radhi lo hi`
    - `dim = x or y or z` = axis of cone
    - `c1,c2 = coords of cone axis in other 2 dimensions (distance units)`
    - `radlo,radhi = cone radii at lo and hi end (distance units)`
    - `lo,hi = bounds of cone in dim (distance units)`
cylinder args = dim c1 c2 radius lo hi
  dim = x or y or z = axis of cylinder
  c1,c2 = coords of cylinder axis in other 2 dimensions (distance units)
  radius = cylinder radius (distance units)
  c1,c2, and radius can be a variable (see below)
  lo,hi = bounds of cylinder in dim (distance units)

ellipsoid args = x y z a b c
  x,y,z = center of ellipsoid (distance units)
  a,b,c = half the length of the principal axes of the ellipsoid (distance units)
  x,y,z,a,b and c can be a variable (see below)

plane args = px py pz nx ny nz
  px,py,pz = point on the plane (distance units)
  nx,ny,nz = direction normal to plane (distance units)

prism args = xlo xhi ylo yhi zlo zhi xy xz yz
  xlo,xhi,ylo,yhi,zlo,zhi = bounds of untilted prism (distance units)
  xy = distance to tilt y in x direction (distance units)
  xz = distance to tilt z in x direction (distance units)
  yz = distance to tilt z in y direction (distance units)

sphere args = x y z radius
  x,y,z = center of sphere (distance units)
  radius = radius of sphere (distance units)
  x,y,z, and radius can be a variable (see below)

union args = N reg-ID1 reg-ID2 ...
  N = # of regions to follow, must be 2 or greater
  reg-ID1,reg-ID2, ... = IDs of regions to join together

intersect args = N reg-ID1 reg-ID2 ...
  N = # of regions to follow, must be 2 or greater
  reg-ID1,reg-ID2, ... = IDs of regions to intersect

• zero or more keyword/arg pairs may be appended
• keyword = side or units or move or rotate or open

  side value = in or out
  in = the region is inside the specified geometry
  out = the region is outside the specified geometry

  units value = lattice or box
  lattice = the geometry is defined in lattice units
  box = the geometry is defined in simulation box units

  move args = v_x v_y v_z
  v_x,v_y,v_z = equal-style variables for x,y,z displacement of region over time (distance units)

  rotate args = v_theta Px Py Pz Rx Ry Rz
  v_theta = equal-style variable for rotation of region over time (in radians)
  Px,Py,Pz = origin for axis of rotation (distance units)
  Rx,Ry,Rz = axis of rotation vector

  open value = integer from 1-6 corresponding to face index (see below)

• accelerated styles (with same args) = block/kk
16.108.2 Examples

```
region 1 block -3.0 5.0 INF 10.0 INF INF
region 2 sphere 0.0 0.0 0.0 5 side out

region openbox block 0 10 0 10 0 10 open 5 open 6 units box
region funnel cone z 10 10 2 5 0 10 open 1 units box
```

16.108.3 Description

This command defines a geometric region of space. Various other commands use regions. For example, the region can be filled with atoms via the `create_atoms` command. Or a bounding box around the region, can be used to define the simulation box via the `create_box` command. Or the atoms in the region can be identified as a group via the `group` command, or deleted via the `delete_atoms` command. Or the surface of the region can be used as a boundary wall via the `fix wall/region` command.

Commands which use regions typically test whether an atom’s position is contained in the region or not. For this purpose, coordinates exactly on the region boundary are considered to be interior to the region. This means, for example, for a spherical region, an atom on the sphere surface would be part of the region if the sphere were defined with the `side in` keyword, but would not be part of the region if it were defined using the `side out` keyword. See more details on the `side` keyword below.

Normally, regions in LAMMPS are “static”, meaning their geometric extent does not change with time. If the `move` or `rotate` keyword is used, as described below, the region becomes “dynamic”, meaning it’s location or orientation changes with time. This may be useful, for example, when thermostatting a region, via the compute temp/region command, or when the `fix wall/region` command uses a region surface as a bounding wall on particle motion, i.e. a rotating container.

The `delete` style removes the named region. Since there is little overhead to defining extra regions, there is normally no need to do this, unless you are defining and discarding large numbers of regions in your input script.

The lo/hi values for `block` or `cone` or `cylinder` or `prism` styles can be specified as EDGE or INF. EDGE means they extend all the way to the global simulation box boundary. Note that this is the current box boundary; if the box changes size during a simulation, the region does not. INF means a large negative or positive number (1.0e20), so it should encompass the simulation box even if it changes size. If a region is defined before the simulation box has been created (via `create_box` or `read_data` or `read_restart` commands), then an EDGE or INF parameter cannot be used. For a `prism` region, a non-zero tilt factor in any pair of dimensions cannot be used if both the lo/hi values in either of those dimensions are INF. E.g. if the xy tilt is non-zero, then xlo and xhi cannot both be INF, nor can ylo and yhi.

Note: Regions in LAMMPS do not get wrapped across periodic boundaries, as specified by the `boundary` command. For example, a spherical region that is defined so that it overlaps a periodic boundary is not treated as 2 half-spheres, one on either side of the simulation box.

Note: Regions in LAMMPS are always 3d geometric objects, regardless of whether the `dimension` of a simulation is 2d or 3d. Thus when using regions in a 2d simulation, you should be careful to define the region so that its intersection with the 2d x-y plane of the simulation has the 2d geometric extent you want.

For style `cone`, an axis-aligned cone is defined which is like a `cylinder` except that two different radii (one at each end) can be defined. Either of the radii (but not both) can be 0.0.
For style *cone* and *cylinder*, the c1,c2 params are coordinates in the 2 other dimensions besides the cylinder axis dimension. For dim = x, c1/c2 = y/z; for dim = y, c1/c2 = x/z; for dim = z, c1/c2 = x/y. Thus the third example above specifies a cylinder with its axis in the y-direction located at x = 2.0 and z = 3.0, with a radius of 5.0, and extending in the y-direction from -5.0 to the upper box boundary.

For style *ellipsoid*, an axis-aligned ellipsoid is defined. The ellipsoid has its center at (x,y,z) and is defined by 3 axis-aligned vectors given by A = (a,0,0); B = (0,b,0); C = (0,0,c). Note that although the ellipsoid is specified as axis-aligned it can be rotated via the optional *rotate* keyword.

For style *plane*, a plane is defined which contain the point (px,py,pz) and has a normal vector (nx,ny,nz). The normal vector does not have to be of unit length. The “inside” of the plane is the half-space in the direction of the normal vector; see the discussion of the *side* option below.

For style *prism*, a parallelepiped is defined (it’s too hard to spell parallelepiped in an input script!). The parallelepiped has its “origin” at (xlo,ylo,zlo) and is defined by 3 edge vectors starting from the origin given by A = (xhi-xlo,0,0); B = (xy,yhi-ylo,0); C = (xz,yz,zhi-zlo). Xy,xz,yz can be 0.0 or positive or negative values and are called “tilt factors” because they are the amount of displacement applied to faces of an originally orthogonal box to transform it into the parallelepiped.

A prism region that will be used with the `create_box` command to define a triclinic simulation box must have tilt factors (xy,xz,yz) that do not skew the box more than half the distance of corresponding the parallel box length. For example, if xlo = 2 and xhi = 12, then the x box length is 10 and the xy tilt factor must be between -5 and 5. Similarly, both xz and yz must be between -(xhi-xlo)/2 and +(yhi-ylo)/2. Note that this is not a limitation, since if the maximum tilt factor is 5 (as in this example), then configurations with tilt = ..., -15, -5, 5, 15, 25, ... are all geometrically equivalent.

For style *sphere*, a sphere is defined with its center at (x,y,z) and with radius as its radius.

The *radius* value for styles *sphere* and *cylinder*, and the parameters a,b,c for style *ellipsoid*, can each be specified as an equal-style variable. Likewise, for style *sphere* and *ellipsoid* the x-, y-, and z- coordinates of the center of the sphere/ellipsoid can be specified as an equal-style variable. And for style *cylinder* the two center positions c1 and c2 for the location of the cylinder axes can be specified as an equal-style variable.

If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the radius of the region.

Equal-style variables can specify formulas with various mathematical functions, and include *thermo_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent radius or have a time dependent position of the sphere or cylinder region.

See the *Howto tricilinc* page for a geometric description of triclinic boxes, as defined by LAMMPS, and how to transform these parameters to and from other commonly used triclinic representations.

The *union* style creates a region consisting of the volume of all the listed regions combined. The *intersect* style creates a region consisting of the volume that is common to all the listed regions.

**Note:** The *union* and *intersect* regions operate by invoking methods from their list of sub-regions. Thus you cannot delete the sub-regions after defining a *union* or *intersection* region.

The *side* keyword determines whether the region is considered to be inside or outside of the specified geometry. Using this keyword in conjunction with *union* and *intersect* regions, complex geometries can be built up. For example, if the interior of two spheres were each defined as regions, and a *union* style with *side* = out was constructed listing the region-IDs of the 2 spheres, the resulting region would be all the volume in the simulation box that was outside both of the spheres.

The *units* keyword determines the meaning of the distance units used to define the region for any argument above listed as having distance units. It also affects the scaling of the velocity vector specified with the *vel* keyword, the amplitude
A box value selects standard distance units as defined by the units command, e.g. Angstroms for units = real or metal. A lattice value means the distance units are in lattice spacings. The lattice command must have been previously used to define the lattice spacings which are used as follows:

- For style block, the lattice spacing in dimension x is applied to xlo and xhi, similarly the spacings in dimensions y,z are applied to ylo/yhi and zlo/zhi.
- For style cone, the lattice spacing in argument dim is applied to lo and hi. The spacings in the two radial dimensions are applied to c1 and c2. The two cone radii are scaled by the lattice spacing in the dimension corresponding to c1.
- For style cylinder, the lattice spacing in argument dim is applied to lo and hi. The spacings in the two radial dimensions are applied to c1 and c2. The cylinder radius is scaled by the lattice spacing in the dimension corresponding to c1.
- For style ellipsoid, the lattice spacing in dimensions x,y,z are applied to the ellipsoid center x,y,z. The spacing in dimensions x,y,z are applied to the ellipsoid radii a,b,c respectively.
- For style plane, the lattice spacing in dimension x is applied to px and nx, similarly the spacings in dimensions y,z are applied to py/ny and pz/nz.
- For style prism, the lattice spacing in dimension x is applied to xlo and xhi, similarly for ylo/yhi and zlo/zhi. The lattice spacing in dimension x is applied to xy and xz, and the spacing in dimension y to yz.
- For style sphere, the lattice spacing in dimensions x,y,z are applied to the sphere center x,y,z. The spacing in dimension x is applied to the sphere radius.

If the move or rotate keywords are used, the region is “dynamic”, meaning its location or orientation changes with time. These keywords cannot be used with a union or intersect style region. Instead, the keywords should be used to make the individual sub-regions of the union or intersect region dynamic. Normally, each sub-region should be “dynamic” in the same manner (e.g. rotate around the same point), though this is not a requirement.

The move keyword allows one or more equal-style variables to be used to specify the x,y,z displacement of the region, typically as a function of time. A variable is specified as v_name, where name is the variable name. Any of the three variables can be specified as NULL, in which case no displacement is calculated in that dimension.

Note that equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a region displacement that change as a function of time or spans consecutive runs in a continuous fashion. For the latter, see the start and stop keywords of the run command and the elaplong keyword of thermo_style custom for details.

For example, these commands would displace a region from its initial position, in the positive x direction, effectively at a constant velocity:

```plaintext
variable dx equal ramp(0,10)
region 2 sphere 10.0 10.0 0.0 5 move v_dx NULL NULL
```

Note that the initial displacement is 0.0, though that is not required.

Either of these variables would “wiggle” the region back and forth in the y direction:

```plaintext
variable dy equal swiggle(0,5,100)
variable dysame equal 5*sin(2*PI*elaplong*dt/100)
region 2 sphere 10.0 10.0 0.0 5 move NULL v_dy NULL
```
The *rotate* keyword rotates the region around a rotation axis \( R = (R_x, R_y, R_z) \) that goes through a point \( P = (P_x, P_y, P_z) \). The rotation angle is calculated, presumably as a function of time, by a variable specified as \( v_{\theta} \), where \( \theta \) is the variable name. The variable should generate its result in radians. The direction of rotation for the region around the rotation axis is consistent with the right-hand rule: if your right-hand thumb points along \( R \), then your fingers wrap around the axis in the direction of rotation.

The *move* and *rotate* keywords can be used together. In this case, the displacement specified by the *move* keyword is applied to the \( P \) point of the *rotate* keyword.

The *open* keyword can be used (multiple times) to indicate that one or more faces of the region are ignored for purposes of particle/wall interactions. This keyword is only relevant for regions used by the *fix wall/region* and *fix wall/gran/region* commands. It can be used to create "open" containers where only some of the region faces are walls. For example, a funnel can be created with a *cone* style region that has an open face at the smaller radius for particles to flow out, or at the larger radius for pouring particles into the cone, or both.

Note that using the *open* keyword partly overrides the *side* keyword, since both exterior and interior surfaces of an open region are tested for particle contacts. The exception to this is a *union* or *intersect* region which includes an open sub-region. In that case the *side* keyword is still used to define the union/intersect region volume, and the *open* settings are only applied to the individual sub-regions that use them.

The indices specified as part of the *open* keyword have the following meanings:

For style *block*, indices 1-6 correspond to the xlo, xhi, ylo, yhi, zlo, zhi surfaces of the block. I.e. 1 is the yz plane at \( x = xlo \), 2 is the yz-plane at \( x = xhi \), 3 is the xz plane at \( y = ylo \), 4 is the xz plane at \( y = yhi \), 5 is the xy plane at \( z = zlo \), 6 is the xy plane at \( z = zhi \). In the second-to-last example above, the region is a box open at both xy planes.

For style *prism*, values 1-6 have the same mapping as for style *block*. I.e. in an un-tilted *prism*, *open* indices correspond to the xlo, xhi, ylo, yhi, zlo, zhi surfaces.

For style *cylinder*, index 1 corresponds to the flat end cap at the low coordinate along the cylinder axis, index 2 corresponds to the high-coordinate flat end cap along the cylinder axis, and index 3 is the curved cylinder surface. For example, a *cylinder* region with *open 1 open 2* keywords will be open at both ends (e.g. a section of pipe), regardless of the cylinder orientation.

For style *cone*, the mapping is the same as for style *cylinder*. Index 1 is the low-coordinate flat end cap, index 2 is the high-coordinate flat end cap, and index 3 is the curved cone surface. In the last example above, a *cone* region is defined along the z-axis that is open at the zlo value (e.g. for use as a funnel).

For all other styles, the *open* keyword is ignored. As indicated above, this includes the *intersect* and *union* regions, though their sub-regions can be defined with the *open* keyword.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

**Note:** Currently, only *block* style regions are supported by Kokkos. The code using the region (such as a fix or compute) must also be supported by Kokkos or no acceleration will occur.
16.108.4 Restrictions

A prism cannot be of 0.0 thickness in any dimension; use a small z thickness for 2d simulations. For 2d simulations, the xz and yz parameters must be 0.0.

16.108.5 Related commands

lattice, create_atoms, delete_atoms, group

16.108.6 Default

The option defaults are side = in, units = lattice, and no move or rotation.

16.109 replicate command

16.109.1 Syntax

replicate nx ny nz keyword

nx, ny, nz = replication factors in each dimension

• optional keyword = bbox

bbox = only check atoms in replicas that overlap with a processor’s sub-domain

16.109.2 Examples

replicate 2 3 2

16.109.3 Description

Replicate the current simulation one or more times in each dimension. For example, replication factors of 2,2,2 will create a simulation with 8x as many atoms by doubling the simulation domain in each dimension. A replication factor of 1 in a dimension leaves the simulation domain unchanged. When the new simulation box is created it is also partitioned into a regular 3d grid of rectangular bricks, one per processor, based on the number of processors being used and the settings of the processors command. The partitioning can later be changed by the balance or fix balance commands.

All properties of the atoms are replicated, including their velocities, which may or may not be desirable. New atom IDs are assigned to new atoms, as are molecule IDs. Bonds and other topology interactions are created between pairs of new atoms as well as between old and new atoms. This is done by using the image flag for each atom to “unwrap” it out of the periodic box before replicating it.

This means that any molecular bond you specify in the original data file that crosses a periodic boundary should be between two atoms with image flags that differ by 1. This will allow the bond to be unwrapped appropriately.

The optional keyword bbox uses a bounding box to only check atoms in replicas that overlap with a processor’s sub-domain when assigning atoms to processors. It typically results in a substantial speedup when using the replicate
command on a large number of processors. It does require temporary use of more memory, specifically that each processor can store all atoms in the entire system before it is replicated.

16.109.4 Restrictions

A 2d simulation cannot be replicated in the z dimension.

If a simulation is non-periodic in a dimension, care should be used when replicating it in that dimension, as it may put atoms nearly on top of each other.

**Note:** You cannot use the replicate command on a system which has a molecule that spans the box and is bonded to itself across a periodic boundary, so that the molecule is effectively a loop. A simple example would be a linear polymer chain that spans the simulation box and bonds back to itself across the periodic boundary. More realistic examples would be a CNT (meant to be an infinitely long CNT) or a graphene sheet or a bulk periodic crystal where there are explicit bonds specified between near neighbors. (Note that this only applies to systems that have permanent bonds as specified in the data file. A CNT that is just atoms modeled with the AIREBO potential has no such permanent bonds, so it can be replicated.) The reason replication does not work with those systems is that the image flag settings described above cannot be made consistent. I.e. it is not possible to define images flags so that when every pair of bonded atoms is unwrapped (using the image flags), they will be close to each other. The only way the replicate command could work in this scenario is for it to break a bond, insert more atoms, and re-connect the loop for the larger simulation box. But it is not clever enough to do this. So you will have to construct a larger version of your molecule as a pre-processing step and input a new data file to LAMMPS.

If the current simulation was read in from a restart file (before a run is performed), there must not be any fix information stored in the file for individual atoms. Similarly, no fixes can be defined at the time the replicate command is used that require vectors of atom information to be stored. This is because the replicate command does not know how to replicate that information for new atoms it creates. To work around this restriction, restart files may be converted into data files and fixes may be undefined via the **unfix** command before and redefined after the replicate command.

### 16.110.3 Description

Perform a pseudo simulation run where atom information is read one snapshot at a time from a dump file(s), and energies and forces are computed on the snapshot to produce thermodynamic or other output.

This can be useful in the following kinds of scenarios, after an initial simulation produced the dump file:

- Compute the energy and forces of snapshots using a different potential.
- Calculate one or more diagnostic quantities on the snapshots that were not computed in the initial run. These can also be computed with settings not used in the initial run, e.g., computing an RDF via the `compute rdf` command with a longer cutoff than was used initially.
- Calculate the portion of per-atom forces resulting from a subset of the potential. E.g., compute only Coulombic forces. This can be done by only defining only a Coulombic pair style in the rerun script. Doing this in the original script would result in different (bad) dynamics.

Conceptually, using the rerun command is like running an input script that has a loop in it (see the `next` and `jump` commands). Each iteration of the loop reads one snapshot from the dump file via the `read_dump` command, sets the timestep to the appropriate value, and then invokes a `run` command for zero timesteps to simply compute energy and forces, and any other thermodynamic output or diagnostic info you have defined. This computation also invokes any fixes you have defined that apply constraints to the system, such as `fix shake` or `fix indent`.

Note that a simulation box must already be defined before using the rerun command. This can be done by the `create_box`, `read_data`, or `read_restart` commands.

Also note that reading per-atom information from dump snapshots is limited to the atom coordinates, velocities and image flags as explained in the `read_dump` command. Other atom properties, which may be necessary to compute energies and forces, such as atom charge, or bond topology information for a molecular system, are not read from (or even contained in) dump files. Thus this auxiliary information should be defined in the usual way, e.g., in a data file read in by a `read_data` command, before using the rerun command.
Also note that the frequency of thermodynamic or dump output from the rerun simulation will depend on settings made in the rerun script, the same as for output from any LAMMPS simulation. See further info below as to what that means if the timesteps for snapshots read from dump files do not match the specified output frequency.

If more than one dump file is specified, the dump files are read one after the other in the order specified. It is assumed that snapshot timesteps will be in ascending order. If a snapshot is encountered that is not in ascending order, it will skip the snapshot until it reads one that is. This allows skipping of a duplicate snapshot (same timestep), e.g. that appeared at the end of one file and beginning of the next. However if you specify a series of dump files in an incorrect order (with respect to the timesteps they contain), you may skip large numbers of snapshots.

Note that the dump files specified as part of the dump keyword can be parallel files, i.e. written as multiple files either per processor and/or per snapshot. If that is the case they will also be read in parallel which can make the rerun command operate dramatically faster for large systems. See the page for the read_dump and dump commands which describe how to read and write parallel dump files.

The first, last, every, skip keywords determine which snapshots are read from the dump file(s). Snapshots are skipped until they have a timestep >= Nfirst. When a snapshot with a timestep > Nlast is encountered, the rerun command finishes. Note that the defaults for first and last are to read all snapshots. If the every keyword is set to a value > 0, then only snapshots with timesteps that are a multiple of Nevery are read (the first snapshot is always read). If Nevery = 0, then this criterion is ignored, i.e. every snapshot is read that meets the other criteria. If the skip keyword is used, then after the first snapshot is read, every Nths snapshot is read, where N = Nskip. E.g. if Nskip = 3, then only 1 out of every 3 snapshots is read, assuming the snapshot timestep is also consistent with the other criteria.

Note: Not all dump formats contain the timestep and not all dump readers support reading it. In that case individual snapshots are assigned consecutive timestep numbers starting at 1.

The start and stop keywords do not affect which snapshots are read from the dump file(s). Rather, they have the same meaning that they do for the run command. They only need to be defined if (a) you are using a fix command that changes some value over time, and (b) you want the reference point for elapsed time (from start to stop) to be different than the first and last settings. See the page for individual fixes to see which ones can be used with the start/stop keywords. Note that if you define neither of the start/stop or first/last keywords, then LAMMPS treats the pseudo run as going from 0 to a huge value (effectively infinity). This means that any quantity that a fix scales as a fraction of elapsed time in the run, will essentially remain at its initial value. Also note that an error will occur if you read a snapshot from the dump file with a timestep value larger than the stop setting you have specified.

The post keyword can be used to minimize the output to the screen that happens after a rerun command, similar to the post keyword of the run command. It is set to no by default.

The dump keyword is required and must be the last keyword specified. Its arguments are passed internally to the read_dump command. The first argument following the dump keyword should be the field1 argument of the read_dump command. See the read_dump page for details on the various options it allows for extracting information from the dump file snapshots, and for using that information to alter the LAMMPS simulation.

In general, a LAMMPS input script that uses a rerun command can include and perform all the usual operations of an input script that uses the run command. There are a few exceptions and points to consider, as discussed here.

Fixes that perform time integration, such as fix nve or fix npt are not invoked, since no time integration is performed. Fixes that perturb or constrain the forces on atoms will be invoked, just as they would during a normal run. Examples are fix indent and fix langevin. So you should think carefully as to whether that makes sense for the manner in which you are reprocessing the dump snapshots.

If you only want the rerun script to perform an analysis that does not involve pair interactions, such as use compute msd to calculated displacements over time, you do not need to define a pair style, which may also mean neighbor lists
will not need to be calculated which saves time. The *comm_modify cutoff* command can also be used to insure ghost atoms are acquired from far enough away for operations like bond and angle evaluations, if no pair style is being used.

Every time a snapshot is read, the timestep for the simulation is reset, as if the *reset_timestep* command were used. This command has some restrictions as to what fixes can be defined. See its page for details. For example, the *fix deposit* and *fix dt/reset* fixes are in this category. They also make no sense to use with a rerun command.

If time-averaging fixes like *fix ave/time* are used, they are invoked on timesteps that are a function of their *Nevery*, *Nrepeat*, and *Nfreq* settings. As an example, see the *fix ave/time* page for details. You must insure those settings are consistent with the snapshot timestamps that are read from the dump file(s). If an averaging fix is not invoked on a timestep it expects to be, LAMMPS will flag an error.

The various forms of LAMMPS output, as defined by the *thermo_style*, *thermo*, *dump*, and *restart* commands occur with specified frequency, e.g. every N steps. If the timestep for a dump snapshot is not a multiple of N, then it will be read and processed, but no output will be produced. If you want output for every dump snapshot, you can simply use N=1 for an output frequency, e.g. for thermodynamic output or new dump file output.

---

### 16.110.4 Restrictions

The *rerun* command is subject to all restrictions of the *read_dump* command.

### 16.110.5 Related commands

*read_dump*

### 16.110.6 Default

The option defaults are *first* = 0, *last* = a huge value (effectively infinity), *start* = same as *first*, *stop* = same as *last*, *every* = 0, *skip* = 1, *post* = no;

### 16.111 reset_atom_ids command

#### 16.111.1 Syntax

```
reset_atom_ids keyword values ...

* zero or more keyword/value pairs may be appended
* keyword = *sort*
```

```
sort value = yes or no
```
16.111.2 Examples

reset_atom_ids
reset_atom_ids sort yes

16.111.3 Description

Reset atom IDs for the system, including all the global IDs stored for bond, angle, dihedral, improper topology data. This will create a set of IDs that are numbered contiguously from 1 to N for a N atoms system.

This can be useful to do after performing a “delete_atoms” command for a molecular system. The delete_atoms compress yes option will not perform this operation due to the existence of bond topology. It can also be useful to do after any simulation which has lost atoms, e.g. due to atoms moving outside a simulation box with fixed boundaries (see the “boundary command”), or due to evaporation (see the “fix evaporate” command).

If the sort keyword is used with a setting of yes, then the assignment of new atom IDs will be the same no matter how many processors LAMMPS is running on. This is done by first doing a spatial sort of all the atoms into bins and sorting them within each bin. Because the set of bins is independent of the number of processors, this enables a consistent assignment of new IDs to each atom.

This can be useful to do after using the “create_atoms” command and/or “replicate” command. In general those commands do not guarantee assignment of the same atom ID to the same physical atom when LAMMPS is run on different numbers of processors. Enforcing consistent IDs can be useful for debugging or comparing output from two different runs.

Note that the spatial sort requires communication of atom IDs and coordinates between processors in an all-to-all manner. This is done efficiently in LAMMPS, but it is more expensive than how atom IDs are reset without sorting.

Note: If this command is used before a pair style is defined, an error about bond topology atom IDs not being found may result. This is because the cutoff distance for ghost atom communication was not sufficient to find atoms in bonds, angles, etc that are owned by other processors. The comm_modify cutoff command can be used to correct this issue. Or you can define a pair style before using this command. If you do the former, you should unset the comm_modify cutoff after using reset_atom_ids so that subsequent communication is not inefficient.

16.111.4 Restrictions

16.111.5 Related commands

delete_atoms
16.111.6 Default

By default, sort is no.

16.112 reset_mol_ids command

16.112.1 Syntax

```
reset_mol_ids group-ID keyword value ...
```

- group-ID = ID of group of atoms whose molecule IDs will be reset
- zero or more keyword/value pairs may be appended
- keyword = compress or offset or single
  
  compress value = yes or no
  offset value = Noffset >= -1
  single value = yes or no to treat single atoms (no bonds) as molecules

16.112.2 Examples

```
reset_mol_ids all
reset_mol_ids all offset 10 single yes
reset_mol_ids solvent compress yes offset 100
reset_mol_ids solvent compress no
```

16.112.3 Description

Reset molecule IDs for a group of atoms based on current bond connectivity. This will typically create a new set of molecule IDs for atoms in the group. Only molecule IDs for atoms in the specified group are reset; molecule IDs for atoms not in the group are not changed.

For purposes of this operation, molecules are identified by the current bond connectivity in the system, which may or may not be consistent with the current molecule IDs. A molecule in this context is a set of atoms connected to each other with explicit bonds. The specific algorithm used is the one of compute fragment/atom. Once the molecules are identified and a new molecule ID computed for each, this command will update the current molecule ID for all atoms in the group with the new molecule ID. Note that if the group excludes atoms within molecules, one (physical) molecule may become two or more (logical) molecules. For example if the group excludes atoms in the middle of a linear chain, then each end of the chain is considered an independent molecule and will be assigned a different molecule ID.

This can be a useful operation to perform after running reactive molecular dynamics run with fix bond/react, fix bond/create, or fix bond/break, all of which can change molecule topologies. It can also be useful after molecules have been deleted with the delete_atoms command or after a simulation which has lost molecules, e.g. via the fix evaporate command.

The compress keyword determines how new molecule IDs are computed. If the setting is yes (the default) and there are N molecules in the group, the new molecule IDs will be a set of N contiguous values. See the offset keyword for details on selecting the range of these values. If the setting is no, the molecule ID of every atom in the molecule will be set to the smallest atom ID of any atom in the molecule.

The single keyword determines whether single atoms (not bonded to another atom) are treated as one-atom molecules or not, based on the yes or no setting. If the setting is no (the default), their molecule IDs are set to 0. This setting can
be important if the new molecule IDs will be used as input to other commands such as `compute chunk/atom molecule` or `fix rigid molecule`.

The `offset` keyword is only used if the `compress` setting is `yes`. Its default value is `Noffset = -1`. In that case, if the specified group is `all`, then the new compressed molecule IDs will range from 1 to N. If the specified group is not `all` and the largest molecule ID of atoms outside that group is M, then the new compressed molecule IDs will range from M+1 to M+N, to avoid collision with existing molecule IDs. If an `Noffset` >= 0 is specified, then the new compressed molecule IDs will range from `Noffset`+1 to `Noffset`+N. If the group is not `all` there may be collisions with the molecule IDs of other atoms.

**Note:** The same as explained for the `compute fragment/atom` command, molecules are identified using the current bond topology. This will not account for bonds broken by the `bond_style quartic` command because it does not perform a full update of the bond topology data structures within LAMMPS.

### 16.112.4 Restrictions

none

### 16.112.5 Related commands

`reset_atom_ids, fix bond/react, fix bond/create, fix bond/break, fix evaporate, delete_atoms, compute fragment/atom`

### 16.112.6 Default

The default keyword settings are compress = yes, single = no, and offset = -1.

### 16.113 reset_timestep command

#### 16.113.1 Syntax

```
reset_timestep N keyword values ...
```

- N = timestep number
- zero or more keyword/value pairs may be appended
- keyword = `time`
  - `time value = atime`
  - `atime = accumulated simulation time`
16.113.2 Examples

reset_timestep 0
reset_timestep 4000000
reset_timestep 1000 time 100.0

16.113.3 Description

Set the timestep counter to the specified value. This command usually comes after the timestep has been set by reading a restart file via the `read_restart` command, or a previous simulation run or minimization advanced the timestep.

The optional `time` keyword allows to also set the accumulated simulation time. This is usually the number of timesteps times the size of the timestep, but when using variable size timesteps with `fix dt/reset` it can differ.

The `read_data` and `create_box` commands set the timestep to 0; the `read_restart` command sets the timestep to the value it had when the restart file was written. The same applies to the accumulated simulation time.

16.113.4 Restrictions

This command cannot be used when any fixes are defined that keep track of elapsed time to perform certain kinds of time-dependent operations. Examples are the `fix deposit` and `fix dt/reset` commands. The former adds atoms on specific timesteps. The latter keeps track of accumulated time.

Various fixes use the current timestep to calculate related quantities. If the timestep is reset, this may produce unexpected behavior, but LAMMPS allows the fixes to be defined even if the timestep is reset. For example, commands which thermostat the system, e.g. `fix nvt`, allow you to specify a target temperature which ramps from Tstart to Tstop which may persist over several runs. If you change the timestep, you may induce an instantaneous change in the target temperature.

Resetting the timestep clears flags for `computes` that may have calculated some quantity from a previous run. This means these quantity cannot be accessed by a variable in between runs until a new run is performed. See the `variable` command for more details.

16.113.5 Related commands

16.114 restart command

16.114.1 Syntax

restart 0
restart N root keyword value ...
restart N file1 file2 keyword value ...

16.114. restart command
• \( N \) = write a restart file every this many timesteps
• \( N \) can be a variable (see below)
• \( \text{root} \) = filename to which timestep # is appended
• \( \text{file1,file2} \) = two full filenames, toggle between them when writing file
• zero or more keyword/value pairs may be appended
• keyword = \( \text{fileper or nfile} \)

\[
\text{fileper arg} = Np
\]
\( Np \) = write one file for every this many processors

\[
\text{nfile arg} = Nf
\]
\( Nf \) = write this many files, one from each of \( Nf \) processors

16.114.2 Examples

```
restart 0
restart 1000 poly.restart
restart 1000 poly.restart.mpiio
restart 1000 restart.*.equil
restart 10000 poly.%.1 poly.%.2 nfile 10
restart v_mystep poly.restart
```

16.114.3 Description

Write out a binary restart file with the current state of the simulation every so many timesteps, in either or both of two modes, as a run proceeds. A value of 0 means do not write out any restart files. The two modes are as follows. If one filename is specified, a series of filenames will be created which include the timestep in the filename. If two filenames are specified, only 2 restart files will be created, with those names. LAMMPS will toggle between the 2 names as it writes successive restart files.

Note that you can specify the restart command twice, once with a single filename and once with two filenames. This would allow you, for example, to write out archival restart files every 100000 steps using a single filename, and more frequent temporary restart files every 1000 steps, using two filenames. Using restart 0 will turn off both modes of output.

Similar to \texttt{dump} files, the restart filename(s) can contain two wild-card characters.

If a “*” appears in the single filename, it is replaced with the current timestep value. This is only recognized when a single filename is used (not when toggling back and forth). Thus, the third example above creates restart files as follows: restart.1000.equil, restart.2000.equil, etc. If a single filename is used with no “*”, then the timestep value is appended. E.g. the second example above creates restart files as follows: poly.restart.1000, poly.restart.2000, etc.

If a “%” character appears in the restart filename(s), then one file is written for each processor and the “%” character is replaced with the processor ID from 0 to \( P-1 \). An additional file with the “%” replaced by “base” is also written, which contains global information. For example, the files written on step 1000 for filename restart.% would be restart.base.1000, restart.0.1000, restart.1.1000, …, restart.P-1.1000. This creates smaller files and can be a fast mode of output and subsequent input on parallel machines that support parallel I/O. The optional \texttt{fileper} and \texttt{nfile} keywords discussed below can alter the number of files written.

The restart file can also be written in parallel as one large binary file via the MPI-IO library, which is part of the MPI standard for versions 2.0 and above. Using MPI-IO requires two steps. First, build LAMMPS with its MPIIO package installed, e.g.
Second, use a restart filename which contains “.mpiio”. Note that it does not have to end in “.mpiio”, just contain those characters. Unlike MPI-IO dump files, a particular restart file must be both written and read using MPI-IO.

Restart files are written on timesteps that are a multiple of N but not on the first timestep of a run or minimization. You can use the `write_restart` command to write a restart file before a run begins. A restart file is not written on the last timestep of a run unless it is a multiple of N. A restart file is written on the last timestep of a minimization if N > 0 and the minimization converges.

Instead of a numeric value, N can be specified as an `equal-style variable`, which should be specified as `v_name`, where name is the variable name. In this case, the variable is evaluated at the beginning of a run to determine the next timestep at which a restart file will be written out. On that timestep, the variable will be evaluated again to determine the next timestep, etc. Thus the variable should return timestep values. See the `stagger()` and `logfreq()` and `stride()` math functions for `equal-style variables`, as examples of useful functions to use in this context. Other similar math functions could easily be added as options for `equal-style variables`.

For example, the following commands will write restart files every step from 1100 to 1200, and could be useful for debugging a simulation where something goes wrong at step 1163:

```plaintext
variable s equal stride(1100,1200,1)
restart v_s tmp.restart
```

See the `read_restart` command for information about what is stored in a restart file.

Restart files can be read by a `read_restart` command to restart a simulation from a particular state. Because the file is binary (to enable exact restarts), it may not be readable on another machine. In this case, you can use the `-r command-line switch` to convert a restart file to a data file.

**Note:** Although the purpose of restart files is to enable restarting a simulation from where it left off, not all information about a simulation is stored in the file. For example, the list of fixes that were specified during the initial run is not stored, which means the new input script must specify any fixes you want to use. Even when restart information is stored in the file, as it is for some fixes, commands may need to be re-specified in the new input script, in order to re-use that information. See the `read_restart` command for information about what is stored in a restart file.

The optional `nfile` or `fileper` keywords can be used in conjunction with the “%” wildcard character in the specified restart file name(s). As explained above, the “%” character causes the restart file to be written in pieces, one piece for each of P processors. By default P = the number of processors the simulation is running on. The `nfile` or `fileper` keyword can be used to set P to a smaller value, which can be more efficient when running on a large number of processors.

The `nfile` keyword sets P to the specified Nf value. For example, if Nf = 4, and the simulation is running on 100 processors, 4 files will be written, by processors 0,25,50,75. Each will collect information from itself and the next 24 processors and write it to a restart file.

For the `fileper` keyword, the specified value of Np means write one file for every Np processors. For example, if Np = 4, every fourth processor (0,4,8,12,etc) will collect information from itself and the next 3 processors and write it to a restart file.
16.114.4 Restrictions

To write and read restart files in parallel with MPI-IO, the MPIIO package must be installed.

16.114.5 Related commands

write_restart, read_restart

16.114.6 Default

```
restart 0
```

16.115 run command

16.115.1 Syntax

```
run N keyword values ...
```

- \(N\) = \# of timesteps
- zero or more keyword/value pairs may be appended
- keyword = upto or start or stop or pre or post or every
  - upto \(\) value = none
  - start \(\) value = \(N1\)
    - \(N1\) = timestep at which 1st run started
  - stop \(\) value = \(N2\)
    - \(N2\) = timestep at which last run will end
  - pre \(\) value = no or yes
  - post \(\) value = no or yes
  - every \(\) values = \(M\) \(c1\), \(c2\), \(\ldots\), \(cN\) = one or more LAMMPS commands, each enclosed in quotes
  - \(c1\) = NULL means no command will be invoked

16.115.2 Examples

```
run 10000
run 1000000 upto
run 100 start 0 stop 1000
run 1000 pre no post yes
run 100000 start 0 stop 1000000 every 1000 "print 'Protein Rg = $r'"
run 100000 every 1000 NULL
```
16.115.3 Description

Run or continue dynamics for a specified number of timesteps.

When the run style is respa, N refers to outer loop (largest) timesteps.

A value of N = 0 is acceptable; only the thermodynamics of the system are computed and printed without taking a timestep.

The upto keyword means to perform a run starting at the current timestep up to the specified timestep. E.g. if the current timestep is 10,000 and “run 100000 upto” is used, then an additional 90,000 timesteps will be run. This can be useful for very long runs on a machine that allocates chunks of time and terminate your job when time is exceeded. If you need to restart your script multiple times (reading in the last restart file), you can keep restarting your script with the same run command until the simulation finally completes.

The start or stop keywords can be used if multiple runs are being performed and you want a fix command that changes some value over time (e.g. temperature) to make the change across the entire set of runs and not just a single run. See the page for individual fixes to see which ones can be used with the start/stop keywords.

For example, consider this fix followed by 10 run commands:

```
fix 1 all nvt 200.0 300.0 1.0
run 1000 start 0 stop 10000
run 1000 start 0 stop 10000
...
run 1000 start 0 stop 10000
```

The NVT fix ramps the target temperature from 200.0 to 300.0 during a run. If the run commands did not have the start/stop keywords (just “run 1000”), then the temperature would ramp from 200.0 to 300.0 during the 1000 steps of each run. With the start/stop keywords, the ramping takes place over the 10000 steps of all runs together.

The pre and post keywords can be used to streamline the setup, clean-up, and associated output to the screen that happens before and after a run. This can be useful if you wish to do many short runs in succession (e.g. LAMMPS is being called as a library which is doing other computations between successive short LAMMPS runs).

By default (pre and post = yes), LAMMPS creates neighbor lists, computes forces, and imposes fix constraints before every run. And after every run it gathers and prints timings statistics. If a run is just a continuation of a previous run (i.e. no settings are changed), the initial computation is not necessary; the old neighbor list is still valid as are the forces. So if pre is specified as “no” then the initial setup is skipped, except for printing thermodynamic info. Note that if pre is set to “no” for the very first run LAMMPS performs, then it is overridden, since the initial setup computations must be done.

Note: If your input script changes the system between 2 runs, then the initial setup must be performed to insure the change is recognized by all parts of the code that are affected. Examples are adding a fix or dump or compute, changing a neighbor list parameter, or writing restart file which can migrate atoms between processors. LAMMPS has no easy way to check if this has happened, but it is an error to use the pre no option in this case.

If post is specified as “no”, the full timing summary is skipped; only a one-line summary timing is printed.

The every keyword provides a means of breaking a LAMMPS run into a series of shorter runs. Optionally, one or more LAMMPS commands (c1, c2, ..., cN) will be executed in between the short runs. If used, the every keyword must be the last keyword, since it has a variable number of arguments. Each of the trailing arguments is a single LAMMPS command, and each command should be enclosed in quotes, so that the entire command will be treated as a single argument. This will also prevent any variables in the command from being evaluated until it is executed multiple times during the run. Note that if a command itself needs one of its arguments quoted (e.g. the print command), then you can use a combination of single and double quotes, as in the example above or below.
The every keyword is a means to avoid listing a long series of runs and interleaving commands in your input script. For example, a print command could be invoked or a fix could be redefined, e.g. to reset a thermostat temperature. Or this could be useful for invoking a command you have added to LAMMPS that wraps some other code (e.g. as a library) to perform a computation periodically during a long LAMMPS run. See the Modify doc page for info about how to add new commands to LAMMPS. See the Howto couple page for ideas about how to couple LAMMPS to other codes.

With the every option, N total steps are simulated, in shorter runs of M steps each. After each M-length run, the specified commands are invoked. If only a single command is specified as NULL, then no command is invoked. Thus these lines:

\begin{verbatim}
variable q equal x[100]
run 6000 every 2000 "print 'Coord = $q'"
\end{verbatim}

are the equivalent of:

\begin{verbatim}
variable q equal x[100]
run 2000
print "Coord = $q"
run 2000
print "Coord = $q"
run 2000
print "Coord = $q"
\end{verbatim}

which does 3 runs of 2000 steps and prints the x-coordinate of a particular atom between runs. Note that the variable “$q” will be evaluated afresh each time the print command is executed.

Note that by using the line continuation character “\&”, the run every command can be spread across many lines, though it is still a single command:

\begin{verbatim}
run 10000 every 1000 &
 "print 'Minimum value = $a'" &
 "print 'Maximum value = $b'" &
 "print 'Temp = $c'" &
 "print 'Press = $d'"
\end{verbatim}

If the pre and post options are set to “no” when used with the every keyword, then the first run will do the full setup and the last run will print the full timing summary, but these operations will be skipped for intermediate runs.

**Note:** You might wish to specify a command that exits the run by jumping out of the loop, e.g.

\begin{verbatim}
variable t equal temp
run 10000 every 100 "if '$t < 300.0' then 'jump SELF afterrun'"
\end{verbatim}

However, this will not work. The run command simply executes each command one at a time each time it pauses, then continues the run.

Instead, you should use the fix halt command, which has additional options for how to exit the run.
16.115.4 Restrictions

When not using the *upto* keyword, the number of specified timesteps $N$ must fit in a signed 32-bit integer, so you are limited to slightly more than 2 billion steps ($2^{31}$) in a single run. When using *upto*, $N$ can be larger than a signed 32-bit integer, however the difference between $N$ and the current timestep must still be no larger than $2^{31}$ steps.

However, with or without the *upto* keyword, you can perform successive runs to run a simulation for any number of steps (ok, up to $2^{63}$ total steps). I.e. the timestep counter within LAMMPS is a 64-bit signed integer.

16.115.5 Related commands

`minimize, run_style, temper, fix halt`

16.115.6 Default

The option defaults are start = the current timestep, stop = current timestep + $N$, pre = yes, and post = yes.

16.116 run_style command

16.116.1 Syntax

```
run_style  style  args
```

- **style** = verlet or verlet/split or respa or respa/omp
  
  **verlet** args = none
  
  **verlet/split** args = none
  
  **respa** args = $N$ n1 n2 ... keyword values ...  
                       $N$ = # of levels of rRESPA
                       n1, n2, ... = loop factors between rRESPA levels (N-1 values)
  
  zero or more keyword/value pairings may be appended to the loop factors
  
  keyword = bond or angle or dihedral or improper or
               pair or inner or middle or outer or hybrid or kspace
  
  **bond** value = $M$
                   $M$ = which level (1-N) to compute bond forces in
  
  **angle** value = $M$
                   $M$ = which level (1-N) to compute angle forces in
  
  **dihedral** value = $M$
                     $M$ = which level (1-N) to compute dihedral forces in
  
  **improper** value = $M$
                      $M$ = which level (1-N) to compute improper forces in
  
  **pair** value = $M$
                   $M$ = which level (1-N) to compute pair forces in
  
  **inner** values = $M$ cut1 cut2
                     $M$ = which level (1-N) to compute pair inner forces in
  
  **middle** values = $M$ cut1 cut2
                    $M$ = which level (1-N) to compute pair middle forces in
cut1 = inner cutoff between pair middle and pair outer (distance units)
cut2 = outer cutoff between pair middle and pair outer (distance units)

outer value = M
M = which level (1-N) to compute pair outer forces in

hybrid values = M1 M2 ... (as many values as there are hybrid sub-styles)
M1 = which level (1-N) to compute the first pair_style hybrid sub-style in
M2 = which level (1-N) to compute the second pair_style hybrid sub-style in
M3, etc

kspace value = M
M = which level (1-N) to compute kspace forces in

16.116.2 Examples

run_style verlet
run_style respa 4 2 2 2 bond 1 dihedral 2 pair 3 kspace 4
run_style respa 4 2 2 2 bond 1 dihedral 2 inner 3 5.0 6.0 outer 4 kspace 4
run_style respa 3 4 2 bond 1 hybrid 2 2 1 kspace 3

16.116.3 Description

Choose the style of time integrator used for molecular dynamics simulations performed by LAMMPS.
The verlet style is the velocity form of the Stoermer-Verlet time integration algorithm (velocity-Verlet)

The verlet/split style is also a velocity-Verlet integrator, but it splits the force calculation within each timestep over 2 partitions of processors. See the -partition command-line switch for info on how to run LAMMPS with multiple partitions.

Specifically, this style performs all computation except the kspace_style portion of the force field on the first partition. This include the pair_style, bond_style, neighbor list building, fixes including time integration, and output. The kspace_style portion of the calculation is performed on the second partition.

This is most useful for the PPPM kspaceStyle when its performance on a large number of processors degrades due to the cost of communication in its 3d FFTs. In this scenario, splitting your total processors into 2 subsets of processors, P1 in the first partition and P2 in the second partition, can enable your simulation to run faster. This is because the long-range forces in PPPM can be calculated at the same time as pairwise and bonded forces are being calculated, and the FFTs can actually speed up when running on fewer processors.

To use this style, you must define 2 partitions where P1 is a multiple of P2. Typically having P1 be 3x larger than P2 is a good choice. The 3d processor layouts in each partition must overlay in the following sense. If P1 is a Px1 by Py1 by Pz1 grid, and P2 = Px2 by Py2 by Pz2, then Px1 must be an integer multiple of Px2, and similarly for Py1 a multiple of Py2, and Pz1 a multiple of Pz2.

Typically the best way to do this is to let the first partition choose its own optimal layout, then require the second partition’s layout to match the integer multiple constraint. See the processors command with its part keyword for a way to control this, e.g.

processors * * * part 1 2 multiple

You can also use the partition command to explicitly specify the processor layout on each partition. E.g. for 2 partitions of 60 and 15 processors each:
When you run in 2-partition mode with the `verlet/split` style, the thermodynamic data for the entire simulation will be output to the log and screen file of the first partition, which are `log.lammps.0` and `screen.0` by default; see the `-plog` and `-pscreen` command-line switches to change this. The log and screen file for the second partition will not contain thermodynamic output beyond the first timestep of the run.

See the Accelerator packages page for performance details of the speed-up offered by the `verlet/split` style. One important performance consideration is the assignment of logical processors in the 2 partitions to the physical cores of a parallel machine. The `processors` command has options to support this, and strategies are discussed in Section 5 of the manual.

The `respa` style implements the rRESPA multi-timescale integrator (Tuckerman) with N hierarchical levels, where level 1 is the innermost loop (shortest timestep) and level N is the outermost loop (largest timestep). The loop factor arguments specify what the looping factor is between levels. N1 specifies the number of iterations of level 1 for a single iteration of level 2, N2 is the iterations of level 2 per iteration of level 3, etc. N-1 looping parameters must be specified.

Thus with a 4-level respa setting of “2 2 2” for the 3 loop factors, you could choose to have bond interactions computed 8x per large timestep, angle interactions computed 4x, pair interactions computed 2x, and long-range interactions once per large timestep.

The `timestep` command sets the large timestep for the outermost rRESPA level. Thus if the 3 loop factors are “2 2 2” for 4-level rRESPA, and the outer timestep is set to 4.0 fs, then the inner timestep would be 8x smaller or 0.5 fs. All other LAMMPS commands that specify number of timesteps (e.g. `thermo` for thermo output every N steps, `neigh_modify delay/every` parameters, `dump` every N steps, etc) refer to the outermost timesteps.

The rRESPA keywords enable you to specify at what level of the hierarchy various forces will be computed. If not specified, the defaults are that bond forces are computed at level 1 (innermost loop), angle forces are computed where bond forces are, dihedral forces are computed where angle forces are, improper forces are computed where dihedral forces are, pair forces are computed at the outermost level, and kspace forces are computed where pair forces are. The inner, middle, outer forces have no defaults.

For fixes that support it, the rRESPA level at which a given fix is active, can be selected through the `fix_modify` command.

The `inner` and `middle` keywords take additional arguments for cutoffs that are used by the pairwise force computations. If the 2 cutoffs for `inner` are 5.0 and 6.0, this means that all pairs up to 6.0 apart are computed by the inner force. Those between 5.0 and 6.0 have their force go ramped to 0.0 so the overlap with the next regime (middle or outer) is smooth. The next regime (middle or outer) will compute forces for all pairs from 5.0 outward, with those from 5.0 to 6.0 having their value ramped in an inverse manner.

Note that you can use `inner` and `outer` without using `middle` to split the pairwise computations into two portions instead of three. Unless you are using a very long pairwise cutoff, a 2-way split is often faster than a 3-way split, since it avoids too much duplicate computation of pairwise interactions near the intermediate cutoffs.

Also note that only a few pair potentials support the use of the `inner` and `middle` and `outer` keywords. If not, only the `pair` keyword can be used with that pair style, meaning all pairwise forces are computed at the same rRESPA level. See the doc pages for individual pair styles for details.

Another option for using pair potentials with rRESPA is with the `hybrid` keyword, which requires the use of the `pair_style hybrid` or `hybrid/overlay` command. In this scenario, different sub-styles of the hybrid pair style are evaluated at different rRESPA levels. This can be useful, for example, to set different timesteps for hybrid coarse-grained/all-atom models. The `hybrid` keyword requires as many level assignments as there are hybrid sub-styles, which assigns each sub-style to a rRESPA level, following their order of definition in the `pair_style` command. Since the `hybrid` keyword operates on pair style computations, it is mutually exclusive with either the `pair` or the `inner/middle/outer` keywords.

When using rRESPA (or for any MD simulation) care must be taken to choose a timestep size(s) that insures the Hamiltonian for the chosen ensemble is conserved. For the constant NVE ensemble, total energy must be conserved.
Unfortunately, it is difficult to know *a priori* how well energy will be conserved, and a fairly long test simulation (~10 ps) is usually necessary in order to verify that no long-term drift in energy occurs with the trial set of parameters.

With that caveat, a few rules-of-thumb may be useful in selecting *respa* settings. The following applies mostly to biomolecular simulations using the CHARMM or a similar all-atom force field, but the concepts are adaptable to other problems. Without SHAKE, bonds involving hydrogen atoms exhibit high-frequency vibrations and require a timestep on the order of 0.5 fs in order to conserve energy. The relatively inexpensive force computations for the bonds, angles, impropers, and dihedrals can be computed on this innermost 0.5 fs step. The outermost timestep cannot be greater than 4.0 fs without risking energy drift. Smooth switching of forces between the levels of the rRESPA hierarchy is also necessary to avoid drift, and a 1-2 angstrom “healing distance” (the distance between the outer and inner cutoffs) works reasonably well. We thus recommend the following settings for use of the *respa* style without SHAKE in biomolecular simulations:

```
timestep  4.0
run_style respa 4 2 2 2 inner 2 4.5 6.0 middle 3 8.0 10.0 outer 4
```

With these settings, users can expect good energy conservation and roughly a 2.5 fold speedup over the *verlet* style with a 0.5 fs timestep.

If SHAKE is used with the *respa* style, time reversibility is lost, but substantially longer time steps can be achieved. For biomolecular simulations using the CHARMM or similar all-atom force field, bonds involving hydrogen atoms exhibit high frequency vibrations and require a time step on the order of 0.5 fs in order to conserve energy. These high frequency modes also limit the outer time step sizes since the modes are coupled. It is therefore desirable to use SHAKE with respa in order to freeze out these high frequency motions and increase the size of the time steps in the respa hierarchy. The following settings can be used for biomolecular simulations with SHAKE and rRESPA:

```
fix        2 all shake 0.000001 500 0 m 1.0 a 1
timestep   4.0
run_style  respa 2 2 inner 1 4.0 5.0 outer 2
```

With these settings, users can expect good energy conservation and roughly a 1.5 fold speedup over the *verlet* style with SHAKE and a 2.0 fs timestep.

For non-biomolecular simulations, the *respa* style can be advantageous if there is a clear separation of time scales - fast and slow modes in the simulation. For example, a system of slowly-moving charged polymer chains could be setup as follows:

```
timestep  4.0
run_style respa 2 8
```

This is two-level rRESPA with an 8x difference between the short and long timesteps. The bonds, angles, dihedrals will be computed every 0.5 fs (assuming real units), while the pair and kspace interactions will be computed once every 4 fs. These are the default settings for each kind of interaction, so no additional keywords are necessary.

Even a LJ system can benefit from rRESPA if the interactions are divided by the inner, middle and outer keywords. A 2-fold or more speedup can be obtained while maintaining good energy conservation. In real units, for a pure LJ fluid at liquid density, with a sigma of 3.0 angstroms, and epsilon of 0.1 Kcal/mol, the following settings seem to work well:

```
timestep  36.0
run_style respa 3 3 4 inner 1 3.0 4.0 middle 2 6.0 7.0 outer 3
```

The *respa/omp* style is a variant of *respa* adapted for use with pair, bond, angle, dihedral, improper, or kspace styles with an *omp* suffix. It is functionally equivalent to *respa* but performs additional operations required for managing *omp* styles. For more on *omp* styles see the *Speed omp* doc page. Accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.
You can specify \texttt{respa/omp} explicitly in your input script, or you can use the \texttt{-suffix command-line switch} when you invoke LAMMPS, or you can use the \texttt{suffix} command in your input script.

See the \textit{Accelerator packages} page for more instructions on how to use the accelerated styles effectively.

### 16.116.4 Restrictions

The \texttt{verlet/split} style can only be used if LAMMPS was built with the REPLICA package. Correspondingly the \texttt{respa/omp} style is available only if the OPENMP package was included. See the \textit{Build package} page for more info.

Whenever using rRESPA, the user should experiment with trade-offs in speed and accuracy for their system, and verify that they are conserving energy to adequate precision.

### 16.116.5 Related commands

\texttt{timestep, run}

### 16.116.6 Default

\texttt{run_style verlet}

For \texttt{run_style respa}, the default assignment of interactions to rRESPA levels is as follows:

- bond forces = level 1 (innermost loop)
- angle forces = same level as bond forces
- dihedral forces = same level as angle forces
- improper forces = same level as dihedral forces
- pair forces = level N (outermost level)
- \texttt{kspace} forces = same level as pair forces
- inner, middle, outer forces = no default

### 16.117 set command

#### 16.117.1 Syntax

\texttt{set style ID keyword values ...}

- style = \texttt{atom} or \texttt{type} or \texttt{mol} or \texttt{group} or \texttt{region}
- ID = atom ID range or type range or mol ID range or group ID or region ID
- one or more keyword/value pairs may be appended
keyword = type or type/fraction or type/ratio or type/subset or mol or x or y or z or charge or dipole or dipole/random or quat or spin or spin/random or quat or quat/random or diameter or shape or length or tri or theta or theta/random or angmom or omega or mass or density or density/disc or volume or image or bond or angle or dihedral or improper or sph/e or sph/cv or sph/rho or sph/contact/radius or sph/mass/density or dpd/theta or edpd/temp or edpd/cv or cc or epsilon or i_name or d_name or i2_name or d2_name

**type** value = atom type
  value can be an atom-style variable (see below)

**type/fraction** values = type fraction seed
  type = new atom type
  fraction = approximate fraction of selected atoms to set to new atom type
  seed = random # seed (positive integer)

**type/ratio** values = type fraction seed
  type = new atom type
  fraction = exact fraction of selected atoms to set to new atom type
  seed = random # seed (positive integer)

**type/subset** values = type Nsubset seed
  type = new atom type
  Nsubset = exact number of selected atoms to set to new atom type
  seed = random # seed (positive integer)

**mol** value = molecule ID
  value can be an atom-style variable (see below)

**x, y, z** value = atom coordinate (distance units)
  value can be an atom-style variable (see below)

**vx, vy, vz** value = atom velocity (velocity units)
  value can be an atom-style variable (see below)

**charge** value = atomic charge (charge units)
  value can be an atom-style variable (see below)

**dipole** values = x y z
  x, y, z = orientation of dipole moment vector
  any of x, y, z can be an atom-style variable (see below)

**dipole/random** value = seed Dlen
  seed = random # seed (positive integer) for dipole moment orientations
  Dlen = magnitude of dipole moment (dipole units)

**spin** values = g x y z
  g = magnitude of magnetic spin vector (in Bohr magneton's unit)
  x, y, z = orientation of magnetic spin vector
  any of x, y, z can be an atom-style variable (see below)

**spin/random** value = seed Dlen
  seed = random # seed (positive integer) for magnetic spin orientations
  Dlen = magnitude of magnetic spin vector (in Bohr magneton's unit)

**quat** values = a b c theta
  a, b, c = unit vector to rotate particle around via right-hand rule
  theta = rotation angle (degrees)
  any of a, b, c, theta can be an atom-style variable (see below)

**quat/random** value = seed
  seed = random # seed (positive integer) for quaternion orientations

**diameter** value = diameter of spherical particle (distance units)
  value can be an atom-style variable (see below)

**shape** value = Sx Sy Sz
  Sx, Sy, Sz = 3 diameters of ellipsoid (distance units)

**length** value = len
  len = length of line segment (distance units)
  len can be an atom-style variable (see below)
 tri value = side
   side = side length of equilateral triangle (distance units)
   side can be an atom-style variable (see below)
 theta value = angle (degrees)
   angle = orientation of line segment with respect to x-axis
   angle can be an atom-style variable (see below)
 theta/random value = seed
   seed = random # seed (positive integer) for line segment orientations
 angmom values = Lx Ly Lz
   Lx, Ly, Lz = components of angular momentum vector (distance-mass-velocity units)
   any of Lx, Ly, Lz can be an atom-style variable (see below)
 omega values = Wx Wy Wz
   Wx, Wy, Wz = components of angular velocity vector (radians/time units)
   any of Wx, Wy, Wz can be an atom-style variable (see below)
 mass value = per-atom mass (mass units)
   value can be an atom-style variable (see below)
 density value = particle density for a sphere or ellipsoid (mass/distance^3 units),
   or for a triangle (mass/distance^2 units) or line (mass/distance units) particle
   value can be an atom-style variable (see below)
 density/disc value = particle density for a 2d disc or ellipse (mass/distance^2 units)
   value can be an atom-style variable (see below)
 volume value = particle volume for Peridynamic particle (distance^3 units)
   value can be an atom-style variable (see below)
 image nx ny nz
   nx, ny, nz = which periodic image of the simulation box the atom is in
   any of nx, ny, nz can be an atom-style variable (see below)
 bond value = bond type for all bonds between selected atoms
 angle value = angle type for all angles between selected atoms
 dihedral value = dihedral type for all dihedrals between selected atoms
 improper value = improper type for all impropers between selected atoms
 sph/e value = energy of SPH particles (need units)
   value can be an atom-style variable (see below)
 sph/cv value = heat capacity of SPH particles (need units)
   value can be an atom-style variable (see below)
 sph/rho value = density of SPH particles (need units)
   value can be an atom-style variable (see below)
 smd/mass/density = set particle mass based on volume by providing a mass density
   value can be an atom-style variable (see below)
 dpd/theta value = internal temperature of DPD particles (temperature units)
   value can be an atom-style variable (see below)
   value can be NULL which sets internal temp of each particle to KE temp
 edpd/temp value = temperature of eDPD particles (temperature units)
   value can be an atom-style variable (see below)
 edpd/cv value = volumetric heat capacity of eDPD particles (energy/temperature/volume units)
   value can be an atom-style variable (see below)
 cc values = index cc
   index = index of a chemical species (1 to Nspecies)
   cc = chemical concentration of tDPD particles for a species (mole/volume units)
 epsilon value = dielectric constant of the medium where the atoms reside
 i_name value = custom integer vector with name

```

**16.117.3 Description**

Set one or more properties of one or more atoms. Since atom properties are initially assigned by the `read_data`, `read_restart` or `create_atoms` commands, this command changes those assignments. This can be useful for overriding the default values assigned by the `create_atoms` command (e.g. charge = 0.0). It can be useful for altering pairwise and molecular force interactions, since force-field coefficients are defined in terms of types. It can be used to change the labeling of atoms by atom type or molecule ID when they are output in `dump` files. It can also be useful for debugging purposes; i.e. positioning an atom at a precise location to compute subsequent forces or energy.

Note that the `style` and `ID` arguments determine which atoms have their properties reset. The remaining keywords specify which properties to reset and what the new values are. Some strings like `type` or `mol` can be used as a style and/or a keyword.

This section describes how to select which atoms to change the properties of, via the `style` and `ID` arguments.

The style `atom` selects all the atoms in a range of atom IDs. The style `type` selects all the atoms in a range of types. The style `mol` selects all the atoms in a range of molecule IDs.

In each of the range cases, the range can be specified as a single numeric value, or a wildcard asterisk can be used to specify a range of values. This takes the form “*” or “*n” or “n*” or “m*n”. For example, for the style `type`, if N = the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive). For all the styles except `mol`, the lowest value for the wildcard is 1; for `mol` it is 0.

The style `group` selects all the atoms in the specified group. The style `region` selects all the atoms in the specified geometric region. See the `group` and `region` commands for details of how to specify a group or region.

This section describes the keyword options for which properties to change, for the selected atoms.

Note that except where explicitly prohibited below, all of the keywords allow an `atom-style` or `atomfile-style variable` to be used as the specified value(s). If the value is a variable, it should be specified as v_name, where name is the variable.
name. In this case, the variable will be evaluated, and its resulting per-atom value used to determine the value assigned to each selected atom. Note that the per-atom value from the variable will be ignored for atoms that are not selected via the style and ID settings explained above. A simple way to use per-atom values from the variable to reset a property for all atoms is to use style atom with ID = "*"; this selects all atom IDs.

Atom-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. They can also include per-atom values, such as atom coordinates. Thus it is easy to specify a time-dependent or spatially-dependent set of per-atom values. As explained on the variable doc page, atomfile-style variables can be used in place of atom-style variables, and thus as arguments to the set command. Atomfile-style variables read their per-atoms values from a file.

**Note:** Atom-style and atomfile-style variables return floating point per-atom values. If the values are assigned to an integer variable, such as the molecule ID, then the floating point value is truncated to its integer portion, e.g. a value of 2.6 would become 2.

Keyword **type** sets the atom type for all selected atoms. The specified value must be from 1 to ntypes, where ntypes was set by the create_box command or the atom types field in the header of the data file read by the read_data command.

Keyword **type/fraction** sets the atom type for a fraction of the selected atoms. The actual number of atoms changed is not guaranteed to be exactly the specified fraction (0 <= fraction <= 1), but should be statistically close. Random numbers are used in such a way that a particular atom is changed or not changed, regardless of how many processors are being used. This keyword does not allow use of an atom-style variable.

Keywords **type/ratio** and **type/subset** also set the atom type for a fraction of the selected atoms. The actual number of atoms changed will be exactly the requested number. For **type/ratio** the specified fraction (0 <= fraction <= 1) determines the number. For **type/subset**, the specified Nsubset is the number. An iterative algorithm is used which insures the correct number of atoms are selected, in a perfectly random fashion. Which atoms are selected will change with the number of processors used. These keywords do not allow use of an atom-style variable.

Keyword **mol** sets the molecule ID for all selected atoms. The atom style being used must support the use of molecule IDs.

Keywords x, y, z, and charge set the coordinates or charge of all selected atoms. For charge, the atom style being used must support the use of atomic charge. Keywords vx, vy, and vz set the velocities of all selected atoms.

Keyword **dipole** uses the specified x,y,z values as components of a vector to set as the orientation of the dipole moment vectors of the selected atoms. The magnitude of the dipole moment is set by the length of this orientation vector.

Keyword **dipole/random** randomizes the orientation of the dipole moment vectors for the selected atoms and sets the magnitude of each to the specified Dlen value. For 2d systems, the z component of the orientation is set to 0.0. Random numbers are used in such a way that the orientation of a particular atom is the same, regardless of how many processors are being used. This keyword does not allow use of an atom-style variable.

Keyword **spin** uses the specified g value to set the magnitude of the magnetic spin vectors, and the x,y,z values as components of a vector to set as the orientation of the magnetic spin vectors of the selected atoms.

Keyword **spin/random** randomizes the orientation of the magnetic spin vectors for the selected atoms and sets the magnitude of each to the specified Dlen value.

Keyword **quat** uses the specified values to create a quaternion (4-vector) that represents the orientation of the selected atoms. The particles must define a quaternion for their orientation (e.g. ellipsoids, triangles, body particles) as defined by the atom_style command. Note that particles defined by atom_style ellipsoid have 3 shape parameters. The 3 values must be non-zero for each particle set by this command. They are used to specify the aspect ratios of an ellipsoidal particle, which is oriented by default with its x-axis along the simulation box’s x-axis, and similarly for y and z. If this body is rotated (via the right-hand rule) by an angle theta around a unit rotation vector (a,b,c), then the quaternion that represents its new orientation is given by (cos(theta/2), a*sin(theta/2), b*sin(theta/2), c*sin(theta/2)). The theta and a,b,c values are the arguments to the quat keyword. LAMMPS normalizes the quaternion in case (a,b,c) was not
specified as a unit vector. For 2d systems, the a,b,c values are ignored, since a rotation vector of (0,0,1) is the only valid choice.

Keyword **quat/random** randomizes the orientation of the quaternion for the selected atoms. The particles must define a quaternion for their orientation (e.g. ellipsoids, triangles, body particles) as defined by the atom_style command. Random numbers are used in such a way that the orientation of a particular atom is the same, regardless of how many processors are being used. For 2d systems, only orientations in the xy plane are generated. As with keyword **quat**, for ellipsoidal particles, the 3 shape values must be non-zero for each particle set by this command. This keyword does not allow use of an atom-style variable.

Keyword **diameter** sets the size of the selected atoms. The particles must be finite-size spheres as defined by the atom_style sphere command. The diameter of a particle can be set to 0.0, which means they will be treated as point particles. Note that this command does not adjust the particle mass, even if it was defined with a density, e.g. via the read_data command.

Keyword **shape** sets the size and shape of the selected atoms. The particles must be ellipsoids as defined by the atom_style ellipsoid command. The $S_x$, $S_y$, $S_z$ settings are the 3 diameters of the ellipsoid in each direction. All 3 can be set to the same value, which means the ellipsoid is effectively a sphere. They can also all be set to 0.0 which means the particle will be treated as a point particle. Note that this command does not adjust the particle mass, even if it was defined with a density, e.g. via the read_data command.

Keyword **length** sets the length of selected atoms. The particles must be line segments as defined by the atom_style line command. If the specified value is non-zero the line segment is (re)set to a length = the specified value, centered around the particle position, with an orientation along the x-axis. If the specified value is 0.0, the particle will become a point particle. Note that this command does not adjust the particle mass, even if it was defined with a density, e.g. via the read_data command.

Keyword **tri** sets the size of selected atoms. The particles must be triangles as defined by the atom_style tri command. If the specified value is non-zero the triangle is (re)set to be an equilateral triangle in the xy plane with side length = the specified value, with a centroid at the particle position, with its base parallel to the x axis, and the y-axis running from the center of the base to the top point of the triangle. If the specified value is 0.0, the particle will become a point particle. Note that this command does not adjust the particle mass, even if it was defined with a density, e.g. via the read_data command.

Keyword **theta** sets the orientation of selected atoms. The particles must be line segments as defined by the atom_style line command. The specified value is used to set the orientation angle of the line segments with respect to the x axis.

Keyword **theta/random** randomizes the orientation of theta for the selected atoms. The particles must be line segments as defined by the atom_style line command. Random numbers are used in such a way that the orientation of a particular atom is the same, regardless of how many processors are being used. This keyword does not allow use of an atom-style variable.

Keyword **angmom** sets the angular momentum of selected atoms. The particles must be ellipsoids as defined by the atom_style ellipsoid command or triangles as defined by the atom_style tri command. The angular momentum vector of the particles is set to the 3 specified components.

Keyword **omega** sets the angular velocity of selected atoms. The particles must be spheres as defined by the atom_style sphere command. The angular velocity vector of the particles is set to the 3 specified components.

Keyword **mass** sets the mass of all selected particles. The particles must have a per-atom mass attribute, as defined by the atom_style command. See the “mass” command for how to set mass values on a per-type basis.

Keyword **density** or **density/disc** also sets the mass of all selected particles, but in a different way. The particles must have a per-atom mass attribute, as defined by the atom_style command. If the atom has a radius attribute (see atom_style sphere) and its radius is non-zero, its mass is set from the density and particle volume for 3d systems (the input density is assumed to be in mass/distance^3 units). For 2d, the default is for LAMMPS to model particles with a radius attribute as spheres. However, if the density/disc keyword is used, then they can be modeled as 2d discs (circles). Their mass is set from the density and particle area (the input density is assumed to be in mass/distance^2 units).
If the atom has a shape attribute (see \texttt{atom_style ellipsoid}) and its 3 shape parameters are non-zero, then its mass is set from the density and particle volume (the input density is assumed to be in mass/distance$^3$ units). The \texttt{density/disc} keyword has no effect; it does not (yet) treat 3d ellipsoids as 2d ellipses.

If the atom has a length attribute (see \texttt{atom_style line}) and its length is non-zero, then its mass is set from the density and line segment length (the input density is assumed to be in mass/distance units). If the atom has an area attribute (see \texttt{atom_style tri}) and its area is non-zero, then its mass is set from the density and triangle area (the input density is assumed to be in mass/distance$^2$ units).

If none of these cases are valid, then the mass is set to the density value directly (the input density is assumed to be in mass units).

Keyword \texttt{volume} sets the volume of all selected particles. Currently, only the \texttt{atom_style peri} command defines particles with a volume attribute. Note that this command does not adjust the particle mass.

Keyword \texttt{image} sets which image of the simulation box the atom is considered to be in. An image of 0 means it is inside the box as defined. A value of 2 means add 2 box lengths to get the true value. A value of -1 means subtract 1 box length to get the true value. LAMMPS updates these flags as atoms cross periodic boundaries during the simulation. The flags can be output with atom snapshots via the \texttt{dump} command. If a value of NULL is specified for any of \texttt{nx,ny,nz}, then the current image value for that dimension is unchanged. For non-periodic dimensions only a value of 0 can be specified. This command can be useful after a system has been equilibrated and atoms have diffused one or more box lengths in various directions. This command can then reset the image values for atoms so that they are effectively inside the simulation box, e.g. if a diffusion coefficient is about to be measured via the \texttt{compute msd} command. Care should be taken not to reset the image flags of two atoms in a bond to the same value if the bond straddles a periodic boundary (rather they should be different by +/- 1). This will not affect the dynamics of a simulation, but may mess up analysis of the trajectories if a LAMMPS diagnostic or your own analysis relies on the image flags to unwrap a molecule which straddles the periodic box.

Keywords \texttt{bond}, \texttt{angle}, \texttt{dihedral}, and \texttt{improper}, set the bond type (angle type, etc) of all bonds (angles, etc) of selected atoms to the specified value from 1 to \texttt{nbondtypes} (\texttt{nangletypes}, etc). All atoms in a particular bond (angle, etc) must be selected atoms in order for the change to be made. The value of \texttt{nbondtype} (\texttt{nangletypes}, etc) was set by the \texttt{bond types} (\texttt{angle types}, etc) field in the header of the data file read by the \texttt{read_data} command. These keywords do not allow use of an atom-style variable.

Keywords \texttt{sph/e}, \texttt{sph/cv}, and \texttt{sph/rho} set the energy, heat capacity, and density of smoothed particle hydrodynamics (SPH) particles. See this PDF guide to using SPH in LAMMPS.

Keyword \texttt{smd/mass/density} sets the mass of all selected particles, but it is only applicable to the Smooth Mach Dynamics package MACHDYN. It assumes that the particle volume has already been correctly set and calculates particle mass from the provided mass density value.

Keyword \texttt{smd/contact/radius} only applies to simulations with the Smooth Mach Dynamics package MACHDYN. It sets an interaction radius for computing short-range interactions, e.g. repulsive forces to prevent different individual physical bodies from penetrating each other. Note that the SPH smoothing kernel diameter used for computing long range, nonlocal interactions, is set using the \texttt{diameter} keyword.

Keyword \texttt{dpd/theta} sets the internal temperature of a DPD particle as defined by the DPD-REACT package. If the specified value is a number it must be >= 0.0. If the specified value is NULL, then the kinetic temperature \texttt{Tkin} of each particle is computed as $3/2 \ k \ \text{KE} = 1/2 \ m \ v^2 = 1/2 \ m \ (v_x^2+v_y^2+v_z^2)$. Each particle’s internal temperature is set to \texttt{Tkin}. If the specified value is an atom-style variable, then the variable is evaluated for each particle. If a value >= 0.0, the internal temperature is set to that value. If it is < 0.0, the computation of \texttt{Tkin} is performed and the internal temperature is set to that value.

Keywords \texttt{edpd/temp} and \texttt{edpd/cv} set the temperature and volumetric heat capacity of an eDPD particle as defined by the DPD-MESO package. Currently, only \texttt{atom_style edpd} defines particles with these attributes. The values for the temperature and heat capacity must be positive.

Keyword \texttt{cc} sets the chemical concentration of a tDPD particle for a specified species as defined by the DPD-MESO package. Currently, only \texttt{atom_style tdpd} defines particles with this attribute. An integer for “index” selects a chemical
species (1 to Nspecies) where Nspecies is set by the atom_style command. The value for the chemical concentration must be $\geq 0.0$.

Keyword `epsilon` sets the dielectric constant of a particle, precisely of the medium where the particle resides as defined by the DIELECTRIC package. Currently, only atom_style dielectric defines particles with this attribute. The value for the dielectric constant must be $\geq 0.0$. Note that the set command with this keyword will rescale the particle charge accordingly so that the real charge (e.g., as read from a data file) stays intact. To change the real charges, one needs to use the set command with the `charge` keyword. Care must be taken to ensure that the real and scaled charges, and dielectric constants are consistent.

Keywords `i_name`, `d_name`, `i2_name`, `d2_name` refer to custom per-atom integer and floating-point vectors or arrays that have been added via the `fix property/atom` command. When that command is used specific names are given to each attribute which are the “name” portion of these keywords. For arrays `i2_name` and `d2_name`, the column of the array must also be included following the name in brackets: e.g. `d2_xyz[2]`, `i2_mySpin[3]`.

### 16.117.4 Restrictions

You cannot set an atom attribute (e.g. `mol` or `q` or `volume`) if the atom_style does not have that attribute.

This command requires inter-processor communication to coordinate the setting of bond types (angle types, etc). This means that your system must be ready to perform a simulation before using one of these keywords (force fields set, atom mass set, etc). This is not necessary for other keywords.

Using the region style with the bond (angle, etc) keywords can give unpredictable results if there are bonds (angles, etc) that straddle periodic boundaries. This is because the region may only extend up to the boundary and partner atoms in the bond (angle, etc) may have coordinates outside the simulation box if they are ghost atoms.

### 16.117.5 Related commands

`create_box`, `create_atoms`, `read_data`

### 16.117.6 Default

`none`

### 16.118 shell command

#### 16.118.1 Syntax

```
shell command args
```

- command = `cd` or `mkdir` or `mv` or `rm` or `rmdir` or `putenv` or arbitrary command
  - `cd` arg = `dir`
    - `dir` = directory to change to
  - `mkdir` args = `dir1 dir2 ...`
    - `dir1`, `dir2` = one or more directories to create
  - `mv` args = `old new`
    - `old` = old filename
    - `new` = new filename or destination folder
  - `rm` args = `[-f] file1 file2 ...`
    - `-f` = turn off warnings (optional)
file1, file2 = one or more filenames to delete
rmdir args = dir1 dir2 ...
dir1, dir2 = one or more directories to delete
putenv args = var1=value1 var2=value2
var=value = one of more definitions of environment variables
anything else is passed as a command to the shell for direct execution

16.118.2 Examples

```
shell cd sub1
shell cd ..
shell mkdir tmp1 tmp2/tmp3
shell rmdir tmp1 tmp2
shell mv log.lammps hold/log.1
shell rm TMP/file1 TMP/file2
shell putenv LAMMPS_POTENTIALS=../../potentials
shell my_setup file1 10 file2
shell my_post_process 100 dump.out
```

16.118.3 Description

Execute a shell command. A few simple file-based shell commands are supported directly, in Unix-style syntax. Any command not listed above is passed as-is to the C-library system() call, which invokes the command in a shell. To use the external executable instead of the built-in version one needs to use a full path, for example /bin/rm instead of rm. The built-in commands will also work on operating systems, that do not - by default - provide the corresponding external executables (like mkdir on Windows).

This command provides a ways to invoke custom commands or executables from your input script. For example, you can move files around in preparation for the next section of the input script. Or you can run a program that pre-processes data for input into LAMMPS. Or you can run a program that post-processes LAMMPS output data.

With the exception of cd, all commands, including ones invoked via a system() call, are executed by only a single processor, so that files/directories are not being manipulated by multiple processors concurrently which may result in unexpected errors or corrupted files.

The cd command changes the current working directory similar to the cd command. All subsequent LAMMPS commands that read/write files will use the new directory. All processors execute this command.

The mkdir command creates directories similar to the Unix mkdir -p command. That is, it will attempt to create the entire path of sub-directories if they do not exist yet.

The mv command renames a file and/or moves it to a new directory. It cannot rename files across filesystem boundaries or between drives.

The rm command deletes file similar to the Unix rm command.

The rmdir command deletes directories similar to Unix rmdir command. If a directory is not empty, its contents are also removed recursively similar to the Unix rm -r command.

The putenv command defines or updates an environment variable directly. Since this command does not pass through the shell, no shell variable expansion or globbing is performed, only the usual substitution for LAMMPS variables defined with the variable command is performed. The resulting string is then used literally.

Any other command is passed as-is to the shell along with its arguments as one string, invoked by the C-library system() call. For example, these lines in your input script:
variable n equal 10
variable foo string file2
shell my_setup file1 $n ${foo}

would be the same as invoking
% my_setup file1 10 file2

from a command-line prompt. The executable program “my_setup” is run with 3 arguments: file1 10 file2.

16.118.4 Restrictions
LAMMPS will do a best effort to detect errors and print suitable warnings, but due to the nature of delegating commands to the C-library system() call, this is not always reliable.

16.118.5 Related commands
none

16.118.6 Default
none

16.119 special_bonds command

16.119.1 Syntax

special_bonds keyword values ...

• one or more keyword/value pairs may be appended

• keyword = amber or charmm or dreiding or fene or lj/coul or lj or coul or angle or dihedral
  amber values = none
  charmm values = none
  dreiding values = none
  fene values = none
  lj/coul values = w1,w2,w3
    w1,w2,w3 = weights (0.0 to 1.0) on pairwise Lennard-Jones and Coulombic interactions
  lj values = w1,w2,w3
    w1,w2,w3 = weights (0.0 to 1.0) on pairwise Lennard-Jones interactions
  coul values = w1,w2,w3
    w1,w2,w3 = weights (0.0 to 1.0) on pairwise Coulombic interactions
  angle value = yes or no
  dihedral value = yes or no

special_bonds lj 0.0 0.0 0.5 coul 0.0 0.0 0.0 dihedral yes
```

16.119.3 Description

Set weighting coefficients for pairwise energy and force contributions between pairs of atoms that are also permanently bonded to each other, either directly or via one or two intermediate bonds. These weighting factors are used by nearly all pair styles in LAMMPS that compute simple pairwise interactions. Permanent bonds between atoms are specified by defining the bond topology in the data file read by the `read_data` command. Typically a `bond_style` command is also used to define a bond potential. The rationale for using these weighting factors is that the interaction between a pair of bonded atoms is all (or mostly) specified by the bond, angle, dihedral potentials, and thus the non-bonded Lennard-Jones or Coulombic interaction between the pair of atoms should be excluded (or reduced by a weighting factor).

**Note:** These weighting factors are NOT used by pair styles that compute many-body interactions, since the “bonds” that result from such interactions are not permanent, but are created and broken dynamically as atom conformations change. Examples of pair styles in this category are EAM, MEAM, Stillinger-Weber, Tersoff, COMB, AIREBO, and ReaxFF. In fact, it generally makes no sense to define permanent bonds between atoms that interact via these potentials, though such bonds may exist elsewhere in your system, e.g. when using the `pair_style hybrid` command. Thus LAMMPS ignores `special_bonds` settings when many-body potentials are calculated. Please note, that the existence of explicit bonds for atoms that are described by a many-body potential will alter the neighbor list and thus can render the computation of those interactions invalid, since those pairs are not only used to determine direct pairwise interactions but also neighbors of neighbors and more. The recommended course of action is to remove such bonds, or - if that is not possible - use a special bonds setting of 1.0 1.0 1.0.

**Note:** Unlike some commands in LAMMPS, you cannot use this command multiple times in an incremental fashion: e.g. to first set the LJ settings and then the Coulombic ones. Each time you use this command it sets all the coefficients to default values and only overrides the one you specify, so you should set all the options you need each time you use it. See more details at the bottom of this page.

The Coulomb factors are applied to any Coulomb (charge interaction) term that the potential calculates. The LJ factors are applied to the remaining terms that the potential calculates, whether they represent LJ interactions or not. The weighting factors are a scaling prefactor on the energy and force between the pair of atoms. A value of 1.0 means include the full interaction; a value of 0.0 means exclude it completely.

The first of the 3 coefficients (LJ or Coulombic) is the weighting factor on 1-2 atom pairs, which are pairs of atoms directly bonded to each other. The second coefficient is the weighting factor on 1-3 atom pairs which are those separated by 2 bonds (e.g. the two H atoms in a water molecule). The third coefficient is the weighting factor on 1-4 atom pairs which are those separated by 3 bonds (e.g. the first and fourth atoms in a dihedral interaction). Thus if the 1-2 coefficient is set to 0.0, then the pairwise interaction is effectively turned off for all pairs of atoms bonded to each other. If it is set to 1.0, then that interaction will be at full strength.

**Note:** For purposes of computing weighted pairwise interactions, 1-3 and 1-4 interactions are not defined from the list of angles or dihedrals used by the simulation. Rather, they are inferred topologically from the set of bonds specified when the simulation is defined from a data or restart file (see `read_data` or `read_restart` commands). Thus the set of
1-2,1-3,1-4 interactions that the weights apply to is the same whether angle and dihedral potentials are computed or not, and remains the same even if bonds are constrained, or turned off, or removed during a simulation.

The two exceptions to this rule are (a) if the *angle* or *dihedral* keywords are set to *yes* (see below), or (b) if the *delete_bonds* command is used with the *special* option that re-computes the 1-2,1-3,1-4 topologies after bonds are deleted; see the *delete_bonds* command for more details.

The *amber* keyword sets the 3 coefficients to 0.0, 0.0, 0.5 for LJ interactions and to 0.0, 0.0, 0.8333 for Coulombic interactions, which is the default for a commonly used version of the AMBER force field, where the last value is really $5/6$. See (Cornell) for a description of the AMBER force field.

The *charmm* keyword sets the 3 coefficients to 0.0, 0.0, 0.0 for both LJ and Coulombic interactions, which is the default for a commonly used version of the CHARMM force field. Note that in pair styles *lj*/charmm/*coul*/charmm and *lj*/charmm/*coul*/long the 1-4 coefficients are defined explicitly, and these pairwise contributions are computed as part of the charmm dihedral style - see the *pair_coeff* and *dihedral_style* commands for more information. See (MacKerell) for a description of the CHARMM force field.

The *dreiding* keyword sets the 3 coefficients to 0.0, 0.0, 1.0 for both LJ and Coulombic interactions, which is the default for the Dreiding force field, as discussed in (Mayo).

The *fene* keyword sets the 3 coefficients to 0.0, 1.0, 1.0 for both LJ and Coulombic interactions, which is consistent with a coarse-grained polymer model with FENE bonds. See (Kremer) for a description of FENE bonds.

The *lj*/coul, *lj*, and *coul* keywords allow the 3 coefficients to be set explicitly. The *lj*/coul keyword sets both the LJ and Coulombic coefficients to the same 3 values. The *lj* and *coul* keywords only set either the LJ or Coulombic coefficients. Use both of them if you wish to set the LJ coefficients to different values than the Coulombic coefficients.

The *angle* keyword allows the 1-3 weighting factor to be ignored for individual atom pairs if they are not listed as the first and last atoms in any angle defined in the simulation or as 1,3 or 2,4 atoms in any dihedral defined in the simulation. For example, imagine the 1-3 weighting factor is set to 0.5 and you have a linear molecule with 4 atoms and bonds as follows: 1-2-3-4. If your data file defines 1-2-3 as an angle, but does not define 2-3-4 as an angle or 1-2-3-4 as a dihedral, then the pairwise interaction between atoms 1 and 3 will always be weighted by 0.5, but different force fields use different rules for weighting the pairwise interaction between atoms 2 and 4. If the *angle* keyword is specified as *yes*, then the pairwise interaction between atoms 2 and 4 will be unaffected (full weighting of 1.0). If the *angle* keyword is specified as *no* which is the default, then the 2,4 interaction will also be weighted by 0.5.

The *dihedral* keyword allows the 1-4 weighting factor to be ignored for individual atom pairs if they are not listed as the first and last atoms in any dihedral defined in the simulation. For example, imagine the 1-4 weighting factor is set to 0.5 and you have a linear molecule with 5 atoms and bonds as follows: 1-2-3-4-5. If your data file defines 1-2-3-4 as a dihedral, but does not define 2-3-4-5 as an angle or 1-2-3-4 as a dihedral, then the pairwise interaction between atoms 1 and 3 will always be weighted by 0.5, but different force fields use different rules for weighting the pairwise interaction between atoms 2 and 4. If the *dihedral* keyword is specified as *yes*, then the pairwise interaction between atoms 2 and 4 will be unaffected (full weighting of 1.0). If the *dihedral* keyword is specified as *no* which is the default, then the 2,5 interaction will also be weighted by 0.5.

---

**Note:** LAMMPS stores and maintains a data structure with a list of the first, second, and third neighbors of each atom (within the bond topology of the system). If new bonds are created (or molecules added containing atoms with more special neighbors), the size of this list needs to grow. Note that adding a single bond always adds a new first neighbor but may also induce *many* new second and third neighbors, depending on the molecular topology of your system. Using the *extra/special/per/atom* keyword to either *read_data* or *create_box* reserves empty space in the list for this N additional first, second, or third neighbors to be added. If you do not do this, you may get an error when bonds (or molecules) are added.
Note: If you reuse this command in an input script, you should set all the options you need each time. This command cannot be used a second time incrementally. E.g. these two commands:

```
special_bonds lj 0.0 1.0 1.0
special_bonds coul 0.0 0.0 1.0
```

are not the same as

```
special_bonds lj 0.0 1.0 1.0 coul 0.0 0.0 1.0
```

In the first case you end up with (after the second command):

```
LJ: 0.0 0.0 0.0
Coul: 0.0 0.0 1.0
```

while only in the second case, you get the desired settings of:

```
LJ: 0.0 1.0 1.0
Coul: 0.0 0.0 1.0
```

This happens because the LJ (and Coul) settings are reset to their default values before modifying them, each time the `special_bonds` command is issued.

### 16.119.4 Restrictions

16.120 suffix command

16.120.1 Syntax

```
suffix style args
```

- **style**: `off` or `on` or `gpu` or `intel` or `kk` or `omp` or `opt` or `hybrid`
- **args**: for hybrid style, default suffix to be used and alternative suffix

16.120.2 Examples

```
suffix off
suffix on
suffix gpu
suffix intel
suffix hybrid intel omp
suffix kk
```

16.120.3 Description

This command allows you to use variants of various styles if they exist. In that respect it operates the same as the `-suffix command-line switch`. It also has options to turn off or back on any suffix setting made via the command line.

The specified style can be `gpu`, `intel`, `kk`, `omp`, `opt` or `hybrid`. These refer to optional packages that LAMMPS can be built with, as described on the `Build package` doc page. The "gpu" style corresponds to the GPU package, the "intel" style to the INTEL package, the "kk" style to the KOKKOS package, the "omp" style to the OPENMP package, and the "opt" style to the OPT package.

These are the variants these packages provide:

- **GPU** = a handful of pair styles and the PPPM kspace_style, optimized to run on one or more GPUs or multicore CPU/GPU nodes
- **INTEL** = a collection of pair styles and neighbor routines optimized to run in single, mixed, or double precision on CPUs and Intel(R) Xeon Phi(TM) co-processors.
- **KOKKOS** = a collection of atom, pair, and fix styles optimized to run using the Kokkos library on various kinds of hardware, including GPUs via CUDA and many-core chips via OpenMP or threading.
- **OPENMP** = a collection of pair, bond, angle, dihedral, improper, kspace, compute, and fix styles with support for OpenMP multi-threading
- **OPT** = a handful of pair styles, cache-optimized for faster CPU performance
- **HYBRID** = a combination of two packages can be specified (see below)

As an example, all of the packages provide a `pair_style lj/cut` variant, with style names `lj/cut/opt`, `lj/cut/omp`, `lj/cut/gpu`, `lj/cut/intel`, or `lj/cut/kk`. A variant styles can be specified explicitly in your input script, e.g. `pair_style lj/cut/gpu`. If the suffix command is used with the appropriate style, you do not need to modify your input script. The specified suffix (opt,omp,gpu,intel,kk) is automatically appended whenever your input script command creates a new `atom`, `pair`, `bond`, `angle`, `dihedral`, `improper`, `kspace`, `fix`, `compute`, or `run` style. If the variant version does not exist, the standard version is created.

For “hybrid”, two packages are specified. The first is used whenever available. If a style with the first suffix is not available, the style with the suffix for the second package will be used if available. For example, “hybrid intel omp”
will use styles from the INTEL package as a first choice and styles from the OPENMP package as a second choice if no INTEL variant is available.

If the specified style is off, then any previously specified suffix is temporarily disabled, whether it was specified by a command-line switch or a previous suffix command. If the specified style is on, a disabled suffix is turned back on. The use of these 2 commands lets your input script use a standard LAMMPS style (i.e. a non-accelerated variant), which can be useful for testing or benchmarking purposes. Of course this is also possible by not using any suffix commands, and explicitly appending or not appending the suffix to the relevant commands in your input script.

Note: The default run_style verlet is invoked prior to reading the input script and is therefore not affected by a suffix command in the input script. The KOKKOS package requires “run_style verlet/kk”, so when using the KOKKOS package it is necessary to either use the command line “-sf kk” command or add an explicit “run_style verlet” command to the input script.

  min_style cg &
  neb 0.0 0.01 200 200 20 &
  neb_style fire &
  neb_log log.neb
```

### 16.121.3 Description

Run a temperature accelerated dynamics (TAD) simulation. This method requires two or more partitions to perform NEB transition state searches.

TAD is described in *this paper* by Art Voter. It is a method that uses accelerated dynamics at an elevated temperature to generate results at a specified lower temperature. A good overview of accelerated dynamics methods (AMD) for such systems is given in *this review paper* from the same group. To quote from the review paper: “The dynamical evolution is characterized by vibrational excursions within a potential basin, punctuated by occasional transitions between basins. The transition probability is characterized by \( p(t) = k \exp(-kt) \) where \( k \) is the rate constant.”

TAD is a suitable AMD method for infrequent-event systems, where in addition, the transition kinetics are well-approximated by harmonic transition state theory (hTST). In hTST, the temperature dependence of transition rates follows the Arrhenius relation. As a consequence a set of event times generated in a high-temperature simulation can be mapped to a set of much longer estimated times in the low-temperature system. However, because this mapping involves the energy barrier of the transition event, which is different for each event, the first event at the high temperature may not be the earliest event at the low temperature. TAD handles this by first generating a set of possible events from the current basin. After each event, the simulation is reflected backwards into the current basin. This is repeated until the stopping criterion is satisfied, at which point the event with the earliest low-temperature occurrence time is selected. The stopping criterion is that the confidence measure be greater than 1-\( \delta \). The confidence measure is the probability that no earlier low-temperature event will occur at some later time in the high-temperature simulation. hTST provides an lower bound for this probability, based on the user-specified minimum pre-exponential factor (reciprocal of \( t_{max} \)).

In order to estimate the energy barrier for each event, the TAD method invokes the **NEB** method. Each NEB replica runs on a partition of processors. The current NEB implementation in LAMMPS restricts you to having exactly one processor per replica. For more information, see the documentation for the **neb** command. In the current LAMMPS
implementation of TAD, all the non-NEB TAD operations are performed on the first partition, while the other partitions remain idle. See the Howto replica doc page for further discussion of multi-replica simulations.

A TAD run has several stages, which are repeated each time an event is performed. The logic for a TAD run is as follows:

```
while (time remains):
    while (time < tstop):
        until (event occurs):
            run dynamics for t_event steps
            quench
            run neb calculation using all replicas
            compute tlo from energy barrier
            update earliest event
            update tstop
            reflect back into current basin
        execute earliest event
```

Before this outer loop begins, the initial potential energy basin is identified by quenching (an energy minimization, see below) the initial state and storing the resulting coordinates for reference.

Inside the inner loop, dynamics is run continuously according to whatever integrator has been specified by the user, stopping every $t_{event}$ steps to check if a transition event has occurred. This check is performed by quenching the system and comparing the resulting atom coordinates to the coordinates from the previous basin.

A quench is an energy minimization and is performed by whichever algorithm has been defined by the `min_style` command; its default is the CG minimizer. The tolerances and limits for each quench can be set by the `min` keyword. Note that typically, you do not need to perform a highly-converged minimization to detect a transition event.

The event check is performed by a compute with the specified `compute-ID`. Currently there is only one compute that works with the TAD command, which is the `compute event/displace` command. Other event-checking computes may be added. `Compute event/displace` checks whether any atom in the compute group has moved further than a specified threshold distance. If so, an “event” has occurred.

The NEB calculation is similar to that invoked by the `neb` command, except that the final state is generated internally, instead of being read in from a file. The style of minimization performed by NEB is determined by the `neb_style` keyword and must be a damped dynamics minimizer. The tolerances and limits for each NEB calculation can be set by the `neb` keyword. As discussed on the `neb`, it is often advantageous to use a larger timestep for NEB than for normal dynamics. Since the size of the timestep set by the `timestep` command is used by TAD for performing dynamics, there is a `neb_step` keyword which can be used to set a larger timestep for each NEB calculation if desired.

A key aspect of the TAD method is setting the stopping criterion appropriately. If this criterion is too conservative, then many events must be generated before one is finally executed. Conversely, if this criterion is too aggressive, high-entropy high-barrier events will be over-sampled, while low-entropy low-barrier events will be under-sampled. If the lowest pre-exponential factor is known fairly accurately, then it can be used to estimate $t_{max}$, and the value of $delta$ can be set to the desired confidence level e.g. $delta = 0.05$ corresponds to 95% confidence. However, for systems where the dynamics are not well characterized (the most common case), it will be necessary to experiment with the values of $delta$ and $t_{max}$ to get a good trade-off between accuracy and performance.

A second key aspect is the choice of $t_{hi}$. A larger value greatly increases the rate at which new events are generated. However, too large a value introduces errors due to anharmonicity (not accounted for within hTST). Once again, for any given system, experimentation is necessary to determine the best value of $t_{hi}$.

Five kinds of output can be generated during a TAD run: event statistics, NEB statistics, thermodynamic output by each replica, dump files, and restart files.
Event statistics are printed to the screen and master log.lammps file each time an event is executed. The quantities are the timestep, CPU time, global event number $N$, local event number $M$, event status, energy barrier, time margin, $t_{lo}$ and $delt_{lo}$. The timestep is the usual LAMMPS timestep, which corresponds to the high-temperature time at which the event was detected, in units of timestep. The CPU time is the total processor time since the start of the TAD run. The global event number $N$ is a counter that increments with each executed event. The local event number $M$ is a counter that resets to zero upon entering each new basin. The event status is $E$ when an event is executed, and is $D$ for an event that is detected, while $DF$ is for a detected event that is also the earliest (first) event at the low temperature.

The time margin is the ratio of the high temperature time in the current basin to the stopping time. This last number can be used to judge whether the stopping time is too short or too long (see above). $t_{lo}$ is the low-temperature event time when the current basin was entered, in units of timestep. $delt_{lo}$ is the time of each detected event, measured relative to $t_{lo}$. $delt_{lo}$ is equal to the high-temperature time since entering the current basin, scaled by an exponential factor that depends on the hi/lo temperature ratio and the energy barrier for that event.

On lines for executed events, with status $E$, the global event number is incremented by one, the local event number and time margin are reset to zero, while the global event number, energy barrier, and $delt_{lo}$ match the last event with status $DF$ in the immediately preceding block of detected events. The low-temperature event time $t_{lo}$ is incremented by $delt_{lo}$.

NEB statistics are written to the file specified by the *neb_log* keyword. If the keyword value is “none”, then no NEB statistics are printed out. The statistics are written every $Nevery$ timesteps. See the *neb* command for a full description of the NEB statistics. When invoked from TAD, NEB statistics are never printed to the screen.

Because the NEB calculation must run on multiple partitions, LAMMPS produces additional screen and log files for each partition, e.g. log.lammps.0, log.lammps.1, etc. For the TAD command, these contain the thermodynamic output of each NEB replica. In addition, the log file for the first partition, log.lammps.0, will contain thermodynamic output from short runs and minimizations corresponding to the dynamics and quench operations, as well as a line for each new detected event, as described above.

After the TAD command completes, timing statistics for the TAD run are printed in each replica’s log file, giving a breakdown of how much CPU time was spent in each stage (NEB, dynamics, quenching, etc).

Any *dump files* defined in the input script will be written to during a TAD run at timesteps when an event is executed. This means the requested dump frequency in the *dump* command is ignored. There will be one dump file (per dump command) created for all partitions. The atom coordinates of the dump snapshot are those of the minimum energy configuration resulting from quenching following the executed event. The timesteps written into the dump files correspond to the timestep at which the event occurred and NOT the clock. A dump snapshot corresponding to the initial minimum state used for event detection is written to the dump file at the beginning of each TAD run.

If the *restart* command is used, a single restart file for all the partitions is generated, which allows a TAD run to be continued by a new input script in the usual manner. The restart file is generated after an event is executed. The restart file contains a snapshot of the system in the new quenched state, including the event number and the low-temperature time. The restart frequency specified in the *restart* command is interpreted differently when performing a TAD run. It does not mean the timestep interval between restart files. Instead it means an event interval for executed events. Thus a frequency of 1 means write a restart file every time an event is executed. A frequency of 10 means write a restart file every 10th executed event. When an input script reads a restart file from a previous TAD run, the new script can be run on a different number of replicas or processors.

Note that within a single state, the dynamics will typically temporarily continue beyond the event that is ultimately chosen, until the stopping criterion is satisfied. When the event is eventually executed, the timestep counter is reset to the value when the event was detected. Similarly, after each quench and NEB minimization, the timestep counter is reset to the value at the start of the minimization. This means that the timesteps listed in the replica log files do not always increase monotonically. However, the timestep values printed to the master log file, dump files, and restart files are always monotonically increasing.
16.121.4 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the Build package doc page for more info.

N setting must be integer multiple of \( t_{\text{event}} \).

Runs restarted from restart files written during a TAD run will only produce identical results if the user-specified integrator supports exact restarts. So fix nvt will produce an exact restart, but fix langevin will not.

This command cannot be used when any fixes are defined that keep track of elapsed time to perform time-dependent operations. Examples include the “ave” fixes such as fix ave/chunk. Also fix dt/reset and fix deposit.

16.121.5 Related commands

compute event/displace, min_modify, min_style, run_style, minimize, temper, neb, prd

16.121.6 Default

The option defaults are min = 0.1 0.1 40 50, neb = 0.01 100 100 10, neb_style = quickmin, neb_step = the same timestep set by the timestep command, and neb_log = “none”.

16.122 temper command

16.122.1 Syntax

```
temper N M temp fix-ID seed1 seed2 index
```

- N = total # of timesteps to run
- M = attempt a tempering swap every this many steps
- temp = initial temperature for this ensemble
- fix-ID = ID of the fix that will control temperature during the run
- seed1 = random # seed used to decide on adjacent temperature to partner with
- seed2 = random # seed for Boltzmann factor in Metropolis swap
- index = which temperature (0 to N-1) I am simulating (optional)
16.122.2 Examples

```
temper 100000 100 $t tempfix 0 58728
temper 40000 100 $t tempfix 0 32285 $w
```

16.122.3 Description

Run a parallel tempering or replica exchange simulation using multiple replicas (ensembles) of a system. Two or more replicas must be used.

Each replica runs on a partition of one or more processors. Processor partitions are defined at run-time using the `-partition` command-line switch. Note that if you have MPI installed, you can run a multi-replica simulation with more replicas (partitions) than you have physical processors, e.g. you can run a 10-replica simulation on one or two processors. You will simply not get the performance speed-up you would see with one or more physical processors per replica. See the Howto replica doc page for further discussion.

Each replica’s temperature is controlled at a different value by a fix with `fix-ID` that controls temperature. Most thermostat fix styles (with and without included time integration) are supported. The command will print an error message and abort, if the chosen fix is unsupported. The desired temperature is specified by `temp`, which is typically a variable previously set in the input script, so that each partition is assigned a different temperature. See the variable command for more details. For example:

```
variable t world 300.0 310.0 320.0 330.0
fix myfix all nvt temp $t $t 100.0
temper 100000 100 $t myfix 3847 58382
```

would define 4 temperatures, and assign one of them to the thermostat used by each replica, and to the temper command.

As the tempering simulation runs for `N` timesteps, a temperature swap between adjacent ensembles will be attempted every `M` timesteps. If `seed1` is 0, then the swap attempts will alternate between odd and even pairings. If `seed1` is non-zero then it is used as a seed in a random number generator to randomly choose an odd or even pairing each time. Each attempted swap of temperatures is either accepted or rejected based on a Boltzmann-weighted Metropolis criterion which uses `seed2` in the random number generator.

As a tempering run proceeds, multiple log files and screen output files are created, one per replica. By default these files are named `log.lammps.M` and `screen.M` where `M` is the replica number from 0 to `N-1`, with `N` = # of replicas. See the `-log and -screen command-line switches` for info on how to change these names.

The main screen and log file (log.lammps) will list information about which temperature is assigned to each replica at each thermodynamic output timestep. E.g. for a simulation with 16 replicas:

```
Running on 16 partitions of processors
Step T0 T1 T2 T3 T4 T5 T6 T7 T8 T9 T10 T11 T12 T13 T14 T15
  0  0  1  2  3  4  5  6  7  8  9 10 11 12 13 14 15
500  1  0  3  2  5  4  6  7  8  9 10 11 12 13 14 15
1000  2  0  4  1  5  3  6  7  8  9 10 11 12 14 13 15
1500  2  1  4  0  5  3  6  7  9  8 10 11 12 14 13 15
2000  2  1  3  0  6  4  5  7 10  8  9 11 12 14 13 15
2500  2  1  3  0  6  4  5  7 11  8  9 10 12 14 13 15
...
```

The column headings T0 to TN-1 mean which temperature is currently assigned to the replica 0 to N-1. Thus the columns represent replicas and the value in each column is its temperature (also numbered 0 to N-1). For example, a 0 in the fourth column (column T3, step 2500) means that the fourth replica is assigned temperature 0, i.e. the lowest temperature. You can verify this time sequence of temperature assignments for the Nth replica by comparing...
the Nth column of screen output to the thermodynamic data in the corresponding log.lammps.N or screen.N files as
time proceeds.

You can have each replica create its own dump file in the following manner:

```
variable rep world 0 1 2 3 4 5 6 7
dump 1 all atom 1000 dump.temper.${rep}
```

**Note:** Each replica’s dump file will contain a continuous trajectory for its atoms where the temperature varies over
time as swaps take place involving that replica. If you want a series of dump files, each with snapshots (from all
replicas) that are all at a single temperature, then you will need to post-process the dump files using the information
from the log.lammps file. E.g. you could produce one dump file with snapshots at 300K (from all replicas), another
with snapshots at 310K, etc. Note that these new dump files will not contain “continuous trajectories” for individual
atoms, because two successive snapshots (in time) may be from different replicas. The reorder_remd_traj python script
can do the reordering for you (and additionally also calculated configurational log-weights of trajectory snapshots in
the canonical ensemble). The script can be found in the tools/replica directory while instructions on how to use it is
available in doc/Tools (in brief) and as a README file in tools/replica (in detail).

The last argument `index` in the temper command is optional and is used when restarting a tempering run from a set of
restart files (one for each replica) which had previously swapped to new temperatures. The `index` value (from 0 to N-1,
where N is the # of replicas) identifies which temperature the replica was simulating on the timestep the restart files
were written. Obviously, this argument must be a variable so that each partition has the correct value. Set the variable
to the N values listed in the log file for the previous run for the replica temperatures at that timestep. For example if
the log file listed the following for a simulation with 5 replicas:

```
500000 2 4 0 1 3
```

then a setting of

```
variable w world 2 4 0 1 3
```

would be used to restart the run with a tempering command like the example above with $w$ as the last argument.

16.122.4 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the Build package doc page
for more info.

16.122.5 Related commands

*variable*, *prd*, *neb*
16.122.6 Default

none

16.123 temper/grem command

16.123.1 Syntax

```
temper/grem N M lambda fix-ID thermostat-ID seed1 seed2 index
```

- N = total # of timesteps to run
- M = attempt a tempering swap every this many steps
- lambda = initial lambda for this ensemble
- fix-ID = ID of fix grem
- thermostat-ID = ID of the thermostat that controls kinetic temperature
- seed1 = random # seed used to decide on adjacent temperature to partner with
- seed2 = random # seed for Boltzmann factor in Metropolis swap
- index = which temperature (0 to N-1) I am simulating (optional)

16.123.2 Examples

```
temper/grem 100000 1000 \${lambda} fxgREM fxnvt 0 58728
```

```
temper/grem 40000 100 \${lambda} fxgREM fxnpt 0 32285 \${walkers}
```

16.123.3 Description

Run a parallel tempering or replica exchange simulation in LAMMPS partition mode using multiple generalized replicas (ensembles) of a system defined by `fix grem`, which stands for the generalized replica exchange method (gREM) originally developed by (Kim). It uses non-Boltzmann ensembles to sample over first order phase transitions. The is done by defining replicas with an enthalpy dependent effective temperature

Two or more replicas must be used. See the `temper` command for an explanation of how to run replicas on multiple partitions of one or more processors.

This command is a modification of the `temper` command and has the same dependencies, restraints, and input variables which are discussed there in greater detail.

Instead of temperature, this command performs replica exchanges in lambda as per the generalized ensemble enforced by `fix grem`. The desired lambda is specified by `lambda`, which is typically a variable previously set in the input script, so that each partition is assigned a different temperature. See the `variable` command for more details. For example:

```
variable lambda world 400 420 440 460
fix fxnvt all nvt temp 300.0 300.0 100.0
fix fxgREM all grem \${lambda} -0.05 -50000 fxnvt
temper/grem 100000 100 \${lambda} fxgREM fxnvt 3847 58382
```
would define 4 lambdas with constant kinetic temperature but unique generalized temperature, and assign one of them to fix grem used by each replica, and to the grem command.

As the gREM simulation runs for \( N \) timesteps, a swap between adjacent ensembles will be attempted every \( M \) timesteps. If \( \text{seed1} \) is 0, then the swap attempts will alternate between odd and even pairings. If \( \text{seed1} \) is non-zero then it is used as a seed in a random number generator to randomly choose an odd or even pairing each time. Each attempted swap of temperatures is either accepted or rejected based on a Metropolis criterion, derived for gREM by (Kim), which uses \( \text{seed2} \) in the random number generator.

File management works identical to the temper command. Dump files created by this fix contain continuous trajectories and require post-processing to obtain per-replica information.

The last argument \( \text{index} \) in the grem command is optional and is used when restarting a run from a set of restart files (one for each replica) which had previously swapped to new lambda. This is done using a variable. For example if the log file listed the following for a simulation with 5 replicas:

```
500000 2 4 0 1 3
```

then a setting of

```
variable walkers world 2 4 0 1 3
```

would be used to restart the run with a grem command like the example above with \$\{walkers\} as the last argument. This functionality is identical to temper.

### 16.123.4 Restrictions
This command can only be used if LAMMPS was built with the REPLICA package. See the Build package doc page for more info.

This command must be used with fix grem.

### 16.123.5 Related commands
```
fix grem, temper, variable
```

### 16.123.6 Default

none

### 16.124 temper/npt command

#### 16.124.1 Syntax
```
temper/npt  N  M  temp  fix-ID  seed1  seed2  pressure  index
```

- \( N \) = total # of timesteps to run
- \( M \) = attempt a tempering swap every this many steps
• temp = initial temperature for this ensemble
• fix-ID = ID of the fix that will control temperature and pressure during the run
• seed1 = random # seed used to decide on adjacent temperature to partner with
• seed2 = random # seed for Boltzmann factor in Metropolis swap
• pressure = setpoint pressure for the ensemble
• index = which temperature (0 to N-1) I am simulating (optional)

16.124.2 Examples

```
temper/npt 100000 100 $t nptfix 0 58728 1
temper/npt 2500000 1000 300 nptfix 0 32285 $p
temper/npt 5000000 2000 $t nptfix 0 12523 1 $w
```

16.124.3 Description

Run a parallel tempering or replica exchange simulation using multiple replicas (ensembles) of a system in the isothermal-isobaric (NPT) ensemble. The command temper/npt works like `temper` but requires running replicas in the NPT ensemble instead of the canonical (NVT) ensemble and allows for pressure to be set in the ensembles. These multiple ensembles can run in parallel at different temperatures or different pressures. The acceptance criteria for temper/npt is specific to the NPT ensemble and can be found in references (Okabe) and (Mori).

Apart from the difference in acceptance criteria and the specification of pressure, this command works much like the `temper` command. See the documentation on `temper` for information on how the parallel tempering is handled in general.

16.124.4 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the Build package page for more info.

This command should be used with a fix that maintains the isothermal-isobaric (NPT) ensemble.

16.124.5 Related commands

`temper, variable, fix_npt`

16.124.6 Default

16.125 thermo command

16.125.1 Syntax

```plaintext
thermo N
```

- N = output thermodynamics every N timesteps
- N can be a variable (see below)

16.125.2 Examples

```plaintext
thermo 100
```

16.125.3 Description

Compute and print thermodynamic info (e.g. temperature, energy, pressure) on timesteps that are a multiple of N and at the beginning and end of a simulation. A value of 0 will only print thermodynamics at the beginning and end.

The content and format of what is printed is controlled by the `thermo_style` and `thermo_modify` commands.

Instead of a numeric value, N can be specified as an **equal-style variable**, which should be specified as `v_name`, where name is the variable name. In this case, the variable is evaluated at the beginning of a run to determine the next timestep at which thermodynamic info will be written out. On that timestep, the variable will be evaluated again to determine the next timestep, etc. Thus the variable should return timestep values. See the `stagger()` and `logfreq()` and `stride()` math functions for **equal-style variables**, as examples of useful functions to use in this context. Other similar math functions could easily be added as options for **equal-style variables**.

For example, the following commands will output thermodynamic info at timesteps 0, 10, 20, 30, 100, 200, 300, 1000, 2000, etc:

```plaintext
variable s equal logfreq(10,3,10)
thermo v_s
```

`thermo_style, thermo_modify`
16.125.6 Default

thermo 0

16.126 thermo_modify command

16.126.1 Syntax

thermo_modify keyword value ...

- one or more keyword/value pairs may be listed
- keyword = lost or lost/bond or warn or norm or flush or line or format or temp or press

lost value = error or warn or ignore
lost/bond value = error or warn or ignore
warn value = ignore or reset or default or a number
norm value = yes or no
flush value = yes or no
line value = one or multi or yaml
colname values = ID string, or default

string = new column header name
ID = integer from 1 to N, or integer from -1 to -N, where N = # of quantities being output
- or a thermo keyword or reference to compute, fix, property or variable.
format values = line string, int string, float string, ID string, or none
string = C-style format string
ID = integer from 1 to N, or integer from -1 to -N, where N = # of quantities being output
- or a thermo keyword or reference to compute, fix, property or variable.
temp value = compute ID that calculates a temperature
press value = compute ID that calculates a pressure

16.126.2 Examples

thermo_modify lost ignore flush yes
thermo_modify temp myTemp format 3 %15.8g
thermo_modify temp myTemp format line "%ld %g %g %15.8g"
thermo_modify line multi format float %g
thermo_modify line yaml format none
thermo_modify colname 1 Timestep colname -2 Pressure colname f_1[1] AvgDensity
16.126.3 Description

Set options for how thermodynamic information is computed and printed by LAMMPS.

**Note:** These options apply to the *currently defined* thermo style. When you specify a `thermo_style` command, all thermodynamic settings are restored to their default values, including those previously reset by a thermo_modify command. Thus if your input script specifies a thermo_style command, you should use the thermo_modify command *after* it.

The `lost` keyword determines whether LAMMPS checks for lost atoms each time it computes thermodynamics and what it does if atoms are lost. An atom can be “lost” if it moves across a non-periodic simulation box *boundary* or if it moves more than a box length outside the simulation domain (or more than a processor sub-domain length) before reneighboring occurs. The latter case is typically due to bad dynamics, e.g. too large a timestep or huge forces and velocities. If the value is *ignore*, LAMMPS does not check for lost atoms. If the value is *error* or *warn*, LAMMPS checks and either issues an error or warning. The code will exit with an error and continue with a warning. A warning will only be issued once, the first time an atom is lost. This can be a useful debugging option.

The `lost/bond` keyword determines whether LAMMPS throws an error or not if an atom in a bonded interaction (bond, angle, etc) cannot be found when it creates bonded neighbor lists. By default this is a fatal error. However in some scenarios it may be desirable to only issue a warning or ignore it and skip the computation of the missing bond, angle, etc. An example would be when gas molecules in a vapor are drifting out of the box through a fixed boundary condition (see the *boundary* command). In this case one atom may be deleted before the rest of the molecule is, on a later timestep.

The `warn` keyword allows you to control whether LAMMPS will print warning messages and how many of them. Most warning messages are only printed by MPI rank 0. They are usually pointing out important issues that should be investigated, but LAMMPS cannot determine for certain whether they are an indication of an error.

Some warning messages are printed during a run (or immediately before) each time a specific MPI rank encounters the issue, e.g. bonds that are stretched too far or dihedrals in extreme configurations. These number of these can quickly blow up the size of the log file and screen output. Thus a limit of 100 warning messages is applied by default. The warning count is applied to the entire input unless reset with a `thermo_modify warn reset` command. If there are more warnings than the limit, LAMMPS will print one final warning that it will not print any additional warning messages.

**Note:** The warning limit is enforced on either the per-processor count or the total count across all processors. For efficiency reasons, however, the total count is only updated at steps with thermodynamic output. Thus when running on a large number of processors in parallel, the total number of warnings printed can be significantly larger than the given limit.

Any number after the keyword `warn` will change the warning limit accordingly. With the value *ignore* all warnings will be suppressed, with the value *always* no limit will be applied and warnings will always be printed, with the value *reset* the internal warning counter will be reset to zero, and with the value *default*, the counter is reset and the limit set to 100. An example usage of either *reset* or *default* would be to re-enable warnings that were disabled or have reached the limit during equilibration, where the warnings would be acceptable while the system is still adjusting, but then change to all warnings for the production run, where they would indicate problems that would require a closer look at what is causing them.

The `norm` keyword determines whether various thermodynamic output values are normalized by the number of atoms or not, depending on whether it is set to *yes* or *no*. Different unit styles have different defaults for this setting (see below). Even if `norm` is set to *yes*, a value is only normalized if it is an “extensive” quantity, meaning that it scales with the number of atoms in the system. For the thermo keywords described by the page for the `thermo_style` command, all energy-related keywords are extensive, such as `pe` or `ebond` or `enthalpy`. Other keywords such as `temp` or `press` are “intensive” meaning their value is independent (in a statistical sense) of the number of atoms in the system and thus are never normalized. For thermodynamic output values extracted from fixes and computes in a `thermo_style`
custom command, the page for the individual fix or compute lists whether the value is “extensive” or “intensive” and thus whether it is normalized. Thermodynamic output values calculated by a variable formula are assumed to be “intensive” and thus are never normalized. You can always include a divide by the number of atoms in the variable formula if this is not the case.

The flush keyword invokes a flush operation after thermodynamic info is written to the screen and log file. This insures the output is updated and not buffered (by the application) even if LAMMPS halts before the simulation completes. Please note that this does not affect buffering by the OS or devices, so you may still lose data in case the simulation stops due to a hardware failure.

The line keyword determines whether thermodynamics will be output as a series of numeric values on one line (“one”), in a multi-line format with 3 quantities with text strings per line and a dashed-line header containing the timestep and CPU time (“multi”), or in a YAML format block (“yaml”). This modify option overrides the one, multi, or yaml thermo_style settings.

The colname keyword can be used to change the default header keyword for a column or field of thermodynamic output. The setting for ID string replaces the default text with the provided string. ID can be a positive integer when it represents the column number counting from the left, a negative integer when it represents the column number from the right (i.e. -1 is the last column/keyword), or a thermo keyword (or compute, fix, property, or variable reference) and then it replaces the string for that specific thermo keyword.

The colname keyword can be used multiple times. If multiple colname settings refer to the same keyword, the last setting has precedence. A setting of default clears all previous settings, reverting all values to their default values.

The format keyword can be used to change the default numeric format of any of quantities the thermo_style command outputs. All the specified format strings are C-style formats, e.g. as used by the C/C++ printf() command. The line keyword takes a single argument which is the format string for the entire line of thermo output, with N fields, which you must enclose in quotes if it is more than one field. The int and float keywords take a single format argument and are applied to all integer or floating-point quantities output. The setting for ID string also takes a single format argument which is used for the indexed value in each line. The interpretation is the same as for colname, i.e. a positive integer is the n-th value corresponding to the n-th thermo keyword, a negative integer is counting backwards, and a string matches the entry with the thermo keyword., e.g. the fifth column is output in high precision for “format 5 %20.15g” and the pair energy for “format epair %20.15g”.

The format keyword can be used multiple times. The precedence is for each value in a line of output, the ID format (if specified) is used, else the int or float setting (if specified) is used, else the line setting (if specified) for that value is used, else the default setting is used. A setting of none clears all previous settings, reverting all values to their default format.

Note: The thermo output values step and atoms are stored internally as 8-byte signed integers, rather than the usual 4-byte signed integers. When specifying the format int option you can use a “%d”-style format identifier in the format string and LAMMPS will convert this to the corresponding 8-byte form when it is applied to those keywords. However, when specifying the line or format ID string option for step and natoms, you should specify a format string appropriate for an 8-byte signed integer, e.g. one with “%lld” or “%lld” depending on the platform.

The temp keyword is used to determine how thermodynamic temperature is calculated, which is used by all thermo quantities that require a temperature (“temp”, “press”, “ke”, “etotal”, “enthalpy”, “pxx”, etc). The specified compute ID must have been previously defined by the user via the compute command and it must be a style of compute that calculates a temperature. As described in the thermo_style command, thermo output uses a default compute for temperature with ID = thermo_temp. This option allows the user to override the default.

The press keyword is used to determine how thermodynamic pressure is calculated, which is used by all thermo quantities that require a pressure (“press”, “enthalpy”, “pxx”, etc). The specified compute ID must have been previously defined by the user via the compute command and it must be a style of compute that calculates a pressure. As described in the thermo_style command, thermo output uses a default compute for pressure with ID = thermo_press. This option allows the user to override the default.
Note: If both the \texttt{temp} and \texttt{press} keywords are used in a single \texttt{thermo\_modify} command (or in two separate commands), then the order in which the keywords are specified is important. Note that a \texttt{pressure\ compute} defines its own temperature compute as an argument when it is specified. The \texttt{temp} keyword will override this (for the pressure compute being used by thermodynamics), but only if the \texttt{temp} keyword comes after the \texttt{press} keyword. If the \texttt{temp} keyword comes before the \texttt{press} keyword, then the new pressure compute specified by the \texttt{press} keyword will be unaffected by the \texttt{temp} setting.

thermo_style custom step temp etotal c_myTemp[*] v_abc
```

16.127.3 Description

Set the style and content for printing thermodynamic data to the screen and log files.

Style `one` prints a single line of thermodynamic info that is the equivalent of “thermo_style custom step temp epair emol etotal press”. The line contains only numeric values.

Style `multi` prints a multiple-line listing of thermodynamic info that is the equivalent of “thermo_style custom etotal ke temp pe ebond eangle edihed eimp evdwl ecoul elong press”. The listing contains numeric values and a string ID for each quantity.

Style `yaml` is similar to style `one` but prints the output in YAML format which can be easily read by a variety of script languages and data handling packages. Since LAMMPS may print other output before, after, or in between thermodynamic output, the YAML format content needs to be separated from the rest. All YAML format thermodynamic output can be matched with a regular expression and can thus be extracted with commands like `egrep` as follows:

```plaintext
egrep '^\(keywords:\|data:\|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|--|
Note: When you use a “thermo_style” command, all thermodynamic settings are restored to their default values, including those previously set by a thermo_modify command. Thus if your input script specifies a thermo_style command, you should use the thermo_modify command after it.

Several of the thermodynamic quantities require a temperature to be computed: “temp”, “press”, “ke”, “etotal”, “enthalpy”, “pxx”, etc. By default this is done by using a temperature compute which is created when LAMMPS starts up, as if this command had been issued:

```plaintext
compute thermo_temp all temp
```

See the compute temp command for details. Note that the ID of this compute is thermo_temp and the group is all. You can change the attributes of this temperature (e.g. its degrees-of-freedom) via the compute_modify command. Alternatively, you can directly assign a new compute (that calculates temperature) which you have defined, to be used for calculating any thermodynamic quantity that requires a temperature. This is done via the thermo_modify command.

Several of the thermodynamic quantities require a pressure to be computed: “press”, “enthalpy”, “pxx”, etc. By default this is done by using a pressure compute which is created when LAMMPS starts up, as if this command had been issued:

```plaintext
compute thermo_press all pressure thermo_temp
```

See the compute pressure command for details. Note that the ID of this compute is thermo_press and the group is all. You can change the attributes of this pressure via the compute_modify command. Alternatively, you can directly assign a new compute (that calculates pressure) which you have defined, to be used for calculating any thermodynamic quantity that requires a pressure. This is done via the thermo_modify command.

Several of the thermodynamic quantities require a potential energy to be computed: “pe”, “etotal”, “ebond”, etc. This is done by using a pe compute which is created when LAMMPS starts up, as if this command had been issued:

```plaintext
compute thermo_pe all pe
```

See the compute pe command for details. Note that the ID of this compute is thermo_pe and the group is all. You can change the attributes of this potential energy via the compute_modify command.

The kinetic energy of the system ke is inferred from the temperature of the system with \( \frac{1}{2} k_B T \) of energy for each degree of freedom. Thus, using different compute commands for calculating temperature, via the thermo_modify temp command, may yield different kinetic energies, since different computes that calculate temperature can subtract out different non-thermal components of velocity and/or include different degrees of freedom (translational, rotational, etc).

The potential energy of the system pe will include contributions from fixes if the fix_modify energy yes option is set for a fix that calculates such a contribution. For example, the fix wall/lj93 fix calculates the energy of atoms interacting with the wall. See the doc pages for “individual fixes” to see which ones contribute and whether their default fix_modify energy setting is yes or no.

A long-range tail correction etail for the van der Waals pairwise energy will be non-zero only if the pair_modify tail option is turned on. The etail contribution is included in evdw, epair, pe, and etotal, and the corresponding tail correction to the pressure is included in press and pxx, pyy, etc.

Here is more information on other keywords whose meaning may not be clear:

The step, elapsed, and elaplong keywords refer to timestep count. Step is the current timestep, or iteration count when a minimization is being performed. Elapsed is the number of timesteps elapsed since the beginning of this run. Elaplong
is the number of timesteps elapsed since the beginning of an initial run in a series of runs. See the start and stop keywords for the run for info on how to invoke a series of runs that keep track of an initial starting time. If these keywords are not used, then elapsed and elaplong are the same value.

The dt keyword is the current timestep size in time units. The time keyword is the current elapsed simulation time, also in time units, which is simply (step*dt) if the timestep size has not changed and the timestep has not been reset. If the timestep has changed (e.g. via fix dt/reset) or the timestep has been reset (e.g. via the “reset_timestep” command), then the simulation time is effectively a cumulative value up to the current point.

The cpu keyword is elapsed CPU seconds since the beginning of this run. The tpcpu and spcpu keywords are measures of how fast your simulation is currently running. The tpcpu keyword is simulation time per CPU second, where simulation time is in time units. E.g. for metal units, the tpcpu value would be picoseconds per CPU second. The spcpu keyword is the number of timesteps per CPU second. Both quantities are on-the-fly metrics, measured relative to the last time they were invoked. Thus if you are printing out thermodynamic output every 100 timesteps, the two keywords will continually output the time and timestep rate for the last 100 steps. The tpcpu keyword does not attempt to track any changes in timestep size, e.g. due to using the fix dt/reset command.

The cpuremain keyword estimates the CPU time remaining in the current run, based on the time elapsed thus far. It will only be a good estimate if the CPU time/timestep for the rest of the run is similar to the preceding timesteps. On the initial timestep the value will be 0.0 since there is no history to estimate from. For a minimization run performed by the “minimize” command, the estimate is based on the maxiter parameter, assuming the minimization will proceed for the maximum number of allowed iterations.

The part keyword is useful for multi-replica or multi-partition simulations to indicate which partition this output and this file corresponds to, or for use in a variable to append to a filename for output specific to this partition. See discussion of the -partition command-line switch for details on running in multi-partition mode.

The timeremain keyword is the seconds remaining when a timeout has been configured via the timer timeout command. If the timeout timer is inactive, the value of this keyword is 0.0 and if the timer is expired, it is negative. This allows for example to exit loops cleanly, if the timeout is expired with:

```fortran
if "$\$(timeremain) < 0.0" then "quit 0"
```

The ecouple keyword is cumulative energy change in the system due to any thermostatting or barostatting fixes that are being used. A positive value means that energy has been subtracted from the system (added to the coupling reservoir). See the econserve keyword for an explanation of why this sign choice makes sense.

The econserve keyword is the sum of the potential and kinetic energy of the system as well as the energy that has been transferred by thermostating or barostatting to their coupling reservoirs. I.e. it is $pe + ke + econserve$. Ideally, for a simulation in the NVE, NPH, or NPT ensembles, the econserve quantity should remain constant over time.

The fmax and fnorm keywords are useful for monitoring the progress of an energy minimization. The fmax keyword calculates the maximum force in any dimension on any atom in the system, or the infinity-norm of the force vector for the system. The fnorm keyword calculates the 2-norm or length of the force vector.

The nbuild and ndanger keywords are useful for monitoring neighbor list builds during a run. Note that both these values are also printed with the end-of-run statistics. The nbuild keyword is the number of re-builds during the current run. The ndanger keyword is the number of re-builds that LAMMPS considered potentially “dangerous”. If atom movement triggered neighbor list rebuilding (see the neigh_modify command), then dangerous reneighborings are those that were triggered on the first timestep atom movement was checked for. If this count is non-zero you may wish to reduce the delay factor to insure no force interactions are missed by atoms moving beyond the neighbor distance before a rebuild takes place.

The keywords cella, cellb, cellc, cellalpha, cellbeta, cellgamma, correspond to the usual crystallographic quantities that define the periodic unit cell of a crystal. See the Howto triclinic page for a geometric description of triclinic periodic cells, including a precise definition of these quantities in terms of the internal LAMMPS cell dimensions lx, ly, lz, yz, xz, xy.
For output values from a compute or fix or variable, the bracketed index I used to index a vector, as in `c_ID[I]` or `f_ID[I]` or `v_name[I]`, can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “*" or “*n” or “n*” or “m*n”. If N is the size of the vector, then an asterisk with no numeric values means all indices from 1 to N. A leading asterisk means all indices from 1 to n (inclusive). A trailing asterisk means all indices from n to N (inclusive). A middle asterisk means all indices from m to n (inclusive).

Using a wildcard is the same as if the individual elements of the vector had been listed one by one. E.g. these 2 thermo_style commands are equivalent, since the `compute temp` command creates a global vector with 6 values.

```plaintext
compute myTemp all temp
thermo_style custom step temp etotal c_myTemp[*]
thermo_style custom step temp etotal &
```

**Note:** For a vector-style variable, only the wildcard forms “*n” or “m*n” are allowed. You must specify the upper bound, because vector-style variable lengths are not determined until the variable is evaluated. If n is specified larger than the vector length turns out to be, zeroes are output for missing vector values.

The `c_ID` and `c_ID[I]` and `c_ID[I][J]` keywords allow global values calculated by a compute to be output. As discussed on the `compute` doc page, computes can calculate global, per-atom, or local values. Only global values can be referenced by this command. However, per-atom compute values for an individual atom can be referenced in a variable and the variable referenced by thermo_style custom, as discussed below. See the discussion above for how the I in `c_ID[I]` can be specified with a wildcard asterisk to effectively specify multiple values from a global compute vector.

The ID in the keyword should be replaced by the actual ID of a compute that has been defined elsewhere in the input script. See the `compute` command for details. If the compute calculates a global scalar, vector, or array, then the keyword formats with 0, 1, or 2 brackets will reference a scalar value from the compute.

Note that some computes calculate “intensive” global quantities like temperature; others calculate “extensive” global quantities like kinetic energy that are summed over all atoms in the compute group. Intensive quantities are printed directly without normalization by thermo_style custom. Extensive quantities may be normalized by the total number of atoms in the simulation (NOT the number of atoms in the compute group) when output, depending on the `thermo_modify norm` option being used.

The `f_ID` and `f_ID[I]` and `f_ID[I][J]` keywords allow global values calculated by a fix to be output. As discussed on the `fix` doc page, fixes can calculate global, per-atom, or local values. Only global values can be referenced by this command. However, per-atom fix values can be referenced for an individual atom in a variable and the variable referenced by thermo_style custom, as discussed below. See the discussion above for how the I in `f_ID[I]` can be specified with a wildcard asterisk to effectively specify multiple values from a global fix vector.

The ID in the keyword should be replaced by the actual ID of a fix that has been defined elsewhere in the input script. See the `fix` command for details. If the fix calculates a global scalar, vector, or array, then the keyword formats with 0, 1, or 2 brackets will reference a scalar value from the fix.

Note that some fixes calculate “intensive” global quantities like timestep size; others calculate “extensive” global quantities like energy that are summed over all atoms in the fix group. Intensive quantities are printed directly without normalization by thermo_style custom. Extensive quantities may be normalized by the total number of atoms in the simulation (NOT the number of atoms in the fix group) when output, depending on the `thermo_modify norm` option being used.

The `v_name` keyword allow the current value of a variable to be output. The name in the keyword should be replaced by the variable name that has been defined elsewhere in the input script. Only equal-style and vector-style variables can be referenced; the latter requires a bracketed term to specify the Ith element of the vector calculated by the variable. However, an atom-style variable can be referenced for an individual atom by an equal-style variable and that variable
referenced. See the `variable` command for details. Variables of style `equal` and `vector` and `atom` define a formula which can reference per-atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when evaluated, so this is a very general means of creating thermodynamic output.

Note that equal-style and vector-style variables are assumed to produce “intensive” global quantities, which are thus printed as-is, without normalization by thermo_style custom. You can include a division by “natoms” in the variable formula if this is not the case.

16.127.4 Restrictions

This command must come after the simulation box is defined by a `read_data`, `read_restart`, or `create_box` command.

16.127.5 Related commands

`thermo`, `thermo_modify`, `fix_modify`, `compute temp`, `compute pressure`

16.127.6 Default

`thermo_style one`

16.128 third_order command

Accelerator Variants: third_order/kk

16.128.1 Syntax

`third_order` group-ID style delta args keyword value ...

- group-ID = ID of group of atoms to displace
- style = `regular` or `eskm`
- delta = finite different displacement length (distance units)
- one or more keyword/arg pairs may be appended
  
  keyword = `file` or `binary`
  
  `file` name = name of output file for the third order tensor
  
  `binary` arg = yes or no or gzip
16.128.2 Examples

| third_order | 1 | regular | 0.000001 |
| third_order | 1 | eskm | 0.000001 |
| third_order | 3 | regular | 0.000004 | file third_order.dat |
| third_order | 5 | eskm | 0.00000001 | file third_order.dat binary yes |

16.128.3 Description

Calculate the third order force constant tensor by finite difference of the selected group,

$$
\Phi_{ijk}^{\alpha\beta\gamma} = \frac{\partial^3 U}{\partial x_i,\alpha \partial x_j,\beta \partial x_k,\gamma}
$$

where Phi is the third order force constant tensor.

The output of the command is the tensor, three elements at a time. The three elements correspond to the three gamma elements for a specific i/alpha/j/beta/k. The initial five numbers are i, alpha, j, beta, and k respectively.

If the style eskm is selected, the tensor will be using energy units of 10 J/mol. These units conform to eskm style from the dynamical_matrix command, which will simplify operations using dynamical matrices with third order tensors.

16.128.4 Restrictions

The command collects a 9 times the number of atoms in the group on every single MPI rank, so the memory requirements can be very significant for large systems.

This command is part of the PHONON package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

16.128.5 Related commands

fix phonon dynamical_matrix
16.128.6 Default

The default settings are file = “third_order.dat”, binary = no

16.129 timer command

16.129.1 Syntax

```plaintext
timer args
```

- `args` = one or more of `off` or `loop` or `normal` or `full` or `sync` or `nosync` or `timeout` or `every`

- `off` = do not collect or print any timing information
- `loop` = collect only the total time for the simulation loop
- `normal` = collect timer information broken down by sections (default)
- `full` = like `normal` but also include CPU and thread utilization
- `sync` = explicitly synchronize MPI tasks between sections
- `nosync` = do not synchronize MPI tasks between sections (default)
- `timeout` = set wall time limit to `elapse`
- `every Ncheck` = perform timeout check every `Ncheck` steps

16.129.2 Examples

```plaintext
timer full sync
timer timeout 2:00:00 every 100
```

16.129.3 Description

Select the level of detail at which LAMMPS performs its CPU timings. Multiple keywords can be specified with the `timer` command. For keywords that are mutually exclusive, the last one specified takes precedence.

During a simulation run LAMMPS collects information about how much time is spent in different sections of the code and thus can provide information for determining performance and load imbalance problems. This can be done at different levels of detail and accuracy. For more information about the timing output, see the `Run output` doc page.

The `off` setting will turn all time measurements off. The `loop` setting will only measure the total time for a run and not collect any detailed per section information. With the `normal` setting, timing information for portions of the timestep (pairwise calculations, neighbor list construction, output, etc) are collected as well as information about load imbalances for those sections across processors. The `full` setting adds information about CPU utilization and thread utilization, when multi-threading is enabled.

With the `sync` setting, all MPI tasks are synchronized at each timer call which measures load imbalance for each section more accurately, though it can also slow down the simulation by prohibiting overlapping independent computations on different MPI ranks Using the `nosync` setting (which is the default) turns this synchronization off.

With the `timeout` keyword a wall time limit can be imposed, that affects the `run` and `minimize` commands. This can be convenient when calculations have to comply with execution time limits, e.g. when running under a batch system when you want to maximize the utilization of the batch time slot, especially for runs where the time per timestep varies much and thus it becomes difficult to predict how many steps a simulation can perform for a given wall time limit. This also applies for difficult to converge minimizations. The timeout `elapse` value should be somewhat smaller than
the maximum wall time requested from the batch system, as there is usually some overhead to launch jobs, and it is advisable to write out a restart after terminating a run due to a timeout.

The timeout timer starts when the command is issued. When the time limit is reached, the run or energy minimization will exit on the next step or iteration that is a multiple of the \texttt{Ncheck} value which can be set with the \texttt{every} keyword. Default is checking every 10 steps. After the timer timeout has expired all subsequent run or minimize commands in the input script will be skipped. The remaining time or timer status can be accessed with the \texttt{thermo} variable \texttt{timeremain}, which will be zero, if the timeout is inactive (default setting), it will be negative, if the timeout time is expired and positive if there is time remaining and in this case the value of the variable are the number of seconds remaining.

When the \texttt{timeout} keyword is used a second time, the timer is restarted with a new time limit. The timeout \texttt{elapse} value can be specified as \texttt{off} or \texttt{ unlimited} to impose a no timeout condition (which is the default). The \texttt{elapse} setting can be specified as a single number for seconds, two numbers separated by a colon (MM:SS) for minutes and seconds, or as three numbers separated by colons for hours, minutes, and seconds (H:MM:SS).

The \texttt{every} keyword sets how frequently during a run or energy minimization the wall clock will be checked. This check count applies to the outer iterations or time steps during minimizations or r-RESPA runs, respectively. Checking for timeout too often, can slow a calculation down. Checking too infrequently can make the timeout measurement less accurate, with the run being stopped later than desired.

\textbf{Note:} Using the \texttt{full} and \texttt{sync} options provides the most detailed and accurate timing information, but can also have a negative performance impact due to the overhead of the many required system calls. It is thus recommended to use these settings only when testing tests to identify performance bottlenecks. For calculations with few atoms or a very large number of processors, even the \texttt{normal} setting can have a measurable negative performance impact. In those cases you can just use the \texttt{loop} or \texttt{off} setting.

16.130 timestep command

16.130.1 Syntax

\texttt{timestep dt}

- \texttt{dt} = timestep size (time units)
16.130.2 Examples

```
timestep 2.0
  timestep 0.003
```

16.130.3 Description

Set the timestep size for subsequent molecular dynamics simulations. See the `units` command for the time units associated with each choice of units that LAMMPS supports.

The default value for the timestep size also depends on the choice of units for the simulation; see the default values below.

When the `run style` is `respa`, dt is the timestep for the outer loop (largest) timestep.

16.134 units command

16.134.1 Syntax

```
units style
  • style = lj or real or metal or si or cgs or electron or micro or nano
```

16.134.2 Examples

```
units metal
units lj
```

16.134.3 Description

This command sets the style of units used for a simulation. It determines the units of all quantities specified in the input script and data file, as well as quantities output to the screen, log file, and dump files. Typically, this command is used at the very beginning of an input script.

For all units except \( \text{lj} \), LAMMPS uses physical constants from www.physics.nist.gov. For the definition of Kcal in real units, LAMMPS uses the thermochemical calorie = 4.184 J.

The choice you make for units simply sets some internal conversion factors within LAMMPS. This means that any simulation you perform for one choice of units can be duplicated with any other unit setting LAMMPS supports. In this context “duplicate” means the particles will have identical trajectories and all output generated by the simulation will be identical. This will be the case for some number of timesteps until round-off effects accumulate, since the conversion factors for two different unit systems are not identical to infinite precision.

To perform the same simulation in a different set of units you must change all the unit-based input parameters in your input script and other input files (data file, potential files, etc) correctly to the new units. And you must correctly convert all output from the new units to the old units when comparing to the original results. That is often not simple to do.

Potential or table files may have a `UNITS:` tag included in the first line indicating the unit style those files were created for. If the tag exists, its value will be compared to the chosen unit style and LAMMPS will stop with an error message if there is a mismatch. In some select cases and for specific combinations of unit styles, LAMMPS is capable of automatically converting potential parameters from a file. In those cases, a warning message signaling that an automatic conversion has happened is printed to the screen.

For style \( \text{lj} \), all quantities are unitless. Without loss of generality, LAMMPS sets the fundamental quantities mass, \( \sigma \), \( \epsilon \), and the Boltzmann constant \( k_B = 1 \). The masses, distances, energies you specify are multiples of these fundamental values. The formulas relating the reduced or unitless quantity (with an asterisk) to the same quantity with units is also given. Thus you can use the mass, \( \sigma \), and \( \epsilon \) values for a specific material and convert the results from a unitless LJ simulation into physical quantities. Please note that using these three properties as base, your unit of time has to conform to the relation \( \epsilon = \frac{m\sigma^2}{2} \) since energy is a derived unit (in SI units you equivalently have the relation \( 1 \text{J} = 1 \frac{\text{kg} \cdot \text{m}^2}{\text{s}^2} \)).

- mass = mass or \( m \), where \( M^* = \frac{M}{m} \)
• distance = σ, where \( x^* = \frac{x}{\sigma} \)
• time = \( \tau \), where \( \tau^* = \tau \sqrt{\frac{\epsilon}{m\sigma^2}} \)
• energy = \( \epsilon \), where \( E^* = \frac{E}{\epsilon} \)
• velocity = \( \frac{v}{\sigma} \), where \( v^* = \frac{v}{\sigma} \)
• force = \( \frac{f}{\sigma} \), where \( f^* = \frac{f}{\sigma} \)
• torque = \( \epsilon \), where \( t^* = \frac{t}{\epsilon} \)
• temperature = reduced LJ temperature, where \( T^* = \frac{T}{k_B} \)
• pressure = reduced LJ pressure, where \( p^* = \frac{p}{\epsilon} \)
• dynamic viscosity = reduced LJ viscosity, where \( \eta^* = \frac{\eta}{\epsilon} \)
• charge = reduced LJ charge, where \( q^* = q \frac{1}{\sqrt{4\pi\varepsilon_0\sigma^2}} \)
• dipole = reduced LJ dipole moment, where \( \mu^* = \mu \frac{1}{\sqrt{4\pi\varepsilon_0\sigma^3}} \)
• electric field = force/charge, where \( E^* = \frac{E}{\sqrt{4\pi\varepsilon_0\sigma^2}} \)
• density = mass/volume, where \( \rho^* = \rho \frac{\text{dim}^m}{m} \)

Note that for LJ units, the default mode of thermodynamic output via the \textit{thermo_style} command is to normalize all extensive quantities by the number of atoms. E.g., potential energy is extensive because it is summed over atoms, so it is output as energy/atom. Temperature is intensive since it is already normalized by the number of atoms, so it is output as-is. This behavior can be changed via the \textit{thermo_modify norm} command.

For style \textit{real}, these are the units:
- mass = grams/mole
- distance = Angstroms
- time = femtoseconds
- energy = Kcal/mole
- velocity = Angstroms/femtosecond
- force = Kcal/mole-Angstrom
- torque = Kcal/mole
- temperature = Kelvin
- pressure = atmospheres
- dynamic viscosity = Poise
- charge = multiple of electron charge (1.0 is a proton)
- dipole = charge\(^n\)Angstroms
- electric field = volts/Angstrom
- density = gram/cm\(^3\)dim

For style \textit{metal}, these are the units:
- mass = grams/mole
- distance = Angstroms
- time = picoseconds
• energy = eV
• velocity = Angstroms/picosecond
• force = eV/Angstrom
• torque = eV
• temperature = Kelvin
• pressure = bars
• dynamic viscosity = Poise
• charge = multiple of electron charge (1.0 is a proton)
• dipole = charge*Angstroms
• electric field = volts/Angstrom
• density = gram/cm^dim

For style si, these are the units:
• mass = kilograms
• distance = meters
• time = seconds
• energy = Joules
• velocity = meters/second
• force = Newtons
• torque = Newton-meters
• temperature = Kelvin
• pressure = Pascals
• dynamic viscosity = Pascal*second
• charge = Coulombs (1.6021765e-19 is a proton)
• dipole = Coulombs*meters
• electric field = volts/meter
• density = kilograms/meter^dim

For style cgs, these are the units:
• mass = grams
• distance = centimeters
• time = seconds
• energy = ergs
• velocity = centimeters/second
• force = dynes
• torque = dyne-centimeters
• temperature = Kelvin
• pressure = dyne/cm^2 or barye = 1.0e-6 bars
• dynamic viscosity = Poise
• charge = statcoulombs or esu (4.8032044e-10 is a proton)
• dipole = statcoul-cm = 10^18 debye
• electric field = statvolt/cm or dyne/esu
• density = grams/cm^dim

For style *electron*, these are the units:

• mass = atomic mass units
• distance = Bohr
• time = femtoseconds
• energy = Hartrees
• velocity = Bohr/atomic time units \[1.03275e-15 \text{ seconds}\]
• force = Hartrees/Bohr
• temperature = Kelvin
• pressure = Pascals
• charge = multiple of electron charge (1.0 is a proton)
• dipole moment = Debye
• electric field = volts/cm

For style *micro*, these are the units:

• mass = picograms
• distance = micrometers
• time = microseconds
• energy = picogram-micrometer^2/microsecond^2
• velocity = micrometers/microsecond
• force = picogram-micrometer/microsecond^2
• torque = picogram-micrometer^2/microsecond^2
• temperature = Kelvin
• pressure = picogram/(micrometer-microsecond^2)
• dynamic viscosity = picogram/(micrometer-microsecond)
• charge = picocoulombs (1.6021765e-7 is a proton)
• dipole = picocoulomb-micrometer
• electric field = volt/micrometer
• density = picograms/micrometer^dim

For style *nano*, these are the units:

• mass = attograms
• distance = nanometers
• time = nanoseconds
• energy = attogram-nanometer^2/nanosecond^2
• velocity = nanometers/nanosecond
• force = attogram-nanometer/nanosecond^2
• torque = attogram-nanometer^2/nanosecond^2
• temperature = Kelvin
• pressure = attogram/(nanometer-nanosecond^2)
• dynamic viscosity = attogram/(nanometer-nanosecond)
• charge = multiple of electron charge (1.0 is a proton)
• dipole = charge-nanometer
• electric field = volt/nanometer
• density = attograms/nanometer^dim

The units command also sets the timestep size and neighbor skin distance to default values for each style:
• For style *lj* these are dt = 0.005 \( \tau \) and skin = 0.3 \( \sigma \).
• For style *real* these are dt = 1.0 femtoseconds and skin = 2.0 Angstroms.
• For style *metal* these are dt = 0.001 picoseconds and skin = 2.0 Angstroms.
• For style *si* these are dt = 1.0e-8 seconds and skin = 0.001 meters.
• For style *cgs* these are dt = 1.0e-8 seconds and skin = 0.1 centimeters.
• For style *electron* these are dt = 0.001 femtoseconds and skin = 2.0 Bohr.
• For style *micro* these are dt = 2.0 microseconds and skin = 0.1 micrometers.
• For style *nano* these are dt = 0.00045 nanoseconds and skin = 0.1 nanometers.

```
16.135.3 Description

This command assigns one or more strings to a variable name for evaluation later in the input script or during a simulation.

Variables can thus be useful in several contexts. A variable can be defined and then referenced elsewhere in an input script to become part of a new input command. For variable styles that store multiple strings, the next command can be used to increment which string is assigned to the variable. Variables of style equal store a formula which when evaluated produces a single numeric value which can be output either directly (see the print, fix print, and run every commands) or as part of thermodynamic output (see the thermo_style command), or used as input to an averaging fix (see the fix ave/time command). Variables of style vector store a formula which produces a vector of such values which can be used as input to various averaging fixes, or elements of which can be part of thermodynamic output. Variables of style atom store a formula which when evaluated produces one numeric value per atom which can be output to a dump file (see the dump custom command) or used as input to an averaging fix (see the fix ave/chunk and fix ave/atom commands). Variables of style atomfile can be used anywhere in an input script that atom-style variables are used; they get their per-atom values from a file rather than from a formula. Variables of style python can be hooked to Python functions using code you provide, so that the variable gets its value from the evaluation of the Python code. Variables of style internal are used by a few commands which set their value directly.

Note: As discussed on the Commands parse doc page, an input script can use “immediate” variables, specified as $(formula) with parenthesis, where the numeric formula has the same syntax as equal-style variables described on this page. This is a convenient way to evaluate a formula immediately without using the variable command to define a named variable and then evaluate that variable. The formula can include a trailing colon and format string which determines the precision with which the numeric value is generated. This is also explained on the Commands parse doc page.

In the discussion that follows, the “name” of the variable is the arbitrary string that is the first argument in the variable command. This name can only contain alphanumeric characters and underscores. The “string” is one or more of the subsequent arguments. The “string” can be simple text as in the first example above, it can contain other variables as in the second example, or it can be a formula as in the third example. The “value” is the numeric quantity resulting from evaluation of the string. Note that the same string can generate different values when it is evaluated at different times during a simulation.

Note: When an input script line is encountered that defines a variable of style equal or vector or atom or python that contains a formula or Python code, the formula is NOT immediately evaluated. It will be evaluated every time when the variable is used instead. If you simply want to evaluate a formula in place you can use as so-called. See the section below about “Immediate Evaluation of Variables” for more details on the topic. This is also true of a format style variable since it evaluates another variable when it is invoked.

Variables of style equal and vector and atom can be used as inputs to various other commands which evaluate their formulas as needed, e.g. at different timesteps during a run. In this context, variables of style timer or internal or python can be used in place of an equal-style variable, with the following two caveats.

First, internal-style variables can be used except by commands that set the value stored by the internal variable. When the LAMMPS command evaluates the internal-style variable, it will use the value set (internally) by another command. Second, python-style variables can be used so long as the associated Python function, as defined by the python command, returns a numeric value. When the LAMMPS command evaluates the python-style variable, the Python function will be executed.

Note: When a variable command is encountered in the input script and the variable name has already been specified, the command is ignored. This means variables can NOT be re-defined in an input script (with two exceptions, read further). This is to allow an input script to be processed multiple times without resetting the variables; see the jump or
"include" commands. It also means that using the \textit{command-line switch} \texttt{-var} will override a corresponding index variable setting in the input script.

There are two exceptions to this rule. First, variables of style \texttt{string, getenv, internal, equal, vector, atom, and python} \texttt{ARE} redefined each time the command is encountered. This allows these style of variables to be redefined multiple times in an input script. In a loop, this means the formula associated with an \texttt{equal} or \texttt{atom} style variable can change if it contains a substitution for another variable, e.g. $x$ or $v_x$.

Second, as described below, if a variable is iterated onto the end of its list of strings via the \texttt{next} command, it is removed from the list of active variables, and is thus available to be re-defined in a subsequent variable command. The \texttt{delete} style does the same thing.

The \texttt{Commands parse} page explains how occurrences of a variable name in an input script line are replaced by the variable’s string. The variable name can be referenced as $x$ if the name “x” is a single character, or as $\{\text{LoopVar}\}$ if the name “LoopVar” is one or more characters.

As described below, for variable styles \texttt{index, loop, file, universe, and uloop}, which string is assigned to a variable can be incremented via the \texttt{next} command. When there are no more strings to assign, the variable is exhausted and a flag is set that causes the next \texttt{jump} command encountered in the input script to be skipped. This enables the construction of simple loops in the input script that are iterated over and then exited from.

As explained above, an exhausted variable can be re-used in an input script. The \texttt{delete} style also removes the variable, the same as if it were exhausted, allowing it to be re-defined later in the input script or when the input script is looped over. This can be useful when breaking out of a loop via the \texttt{if} and \texttt{jump} commands before the variable would become exhausted. For example,

\begin{verbatim}
label loop
variable a loop 5
print "A = $a"
if "$a > 2" then "jump in.script break"
next a
jump in.script loop
label break
variable a delete
\end{verbatim}

This section describes how all the various variable styles are defined and what they store. Except for the \texttt{equal} and \texttt{vector} and \texttt{atom} styles, which are explained in the next section.

Many of the styles store one or more strings. Note that a single string can contain spaces (multiple words), if it is enclosed in quotes in the variable command. When the variable is substituted for in another input script command, its returned string will then be interpreted as multiple arguments in the expanded command.

For the \texttt{index} style, one or more strings are specified. Initially, the first string is assigned to the variable. Each time a \texttt{next} command is used with the variable name, the next string is assigned. All processors assign the same string to the variable.

\texttt{Index} style variables with a single string value can also be set by using the \texttt{command-line switch} \texttt{-var}.

The \texttt{loop} style is identical to the \texttt{index} style except that the strings are the integers from 1 to N inclusive, if only one argument N is specified. This allows generation of a long list of runs (e.g. 1000) without having to list N strings in the input script. Initially, the string “1” is assigned to the variable. Each time a \texttt{next} command is used with the variable name, the next string (“2”, “3”, etc) is assigned. All processors assign the same string to the variable. The \texttt{loop} style can also be specified with two arguments N1 and N2. In this case the loop runs from N1 to N2 inclusive, and the string N1 is initially assigned to the variable. N1 $\leq$ N2 and N2 $\geq$ 0 is required.
For the *world* style, one or more strings are specified. There must be one string for each processor partition or “world”. LAMMPS can be run with multiple partitions via the `-partition command-line switch`. This variable command assigns one string to each world. All processors in the world are assigned the same string. The next command cannot be used with *equal* style variables, since there is only one value per world. This style of variable is useful when you wish to run different simulations on different partitions, or when performing a parallel tempering simulation (see the `temper` command), to assign different temperatures to different partitions.

For the *universe* style, one or more strings are specified. There must be at least as many strings as there are processor partitions or “worlds”. LAMMPS can be run with multiple partitions via the `-partition command-line switch`. This variable command initially assigns one string to each world. When a `next` command is encountered using this variable, the first processor partition to encounter it, is assigned the next available string. This continues until all the variable strings are consumed. Thus, this command can be used to run 50 simulations on 8 processor partitions. The simulations will be run one after the other on whatever partition becomes available, until they are all finished. *Universe* style variables are incremented using the files “tmp.lammps.variable” and “tmp.lammps.variable.lock” which you will see in your directory during such a LAMMPS run.

The *uloop* style is identical to the *universe* style except that the strings are the integers from 1 to N. This allows generation of long list of runs (e.g. 1000) without having to list N strings in the input script.

For the *string* style, a single string is assigned to the variable. Two differences between this style and using the *index* style exist: a variable with *string* style can be redefined, e.g. by another command later in the input script, or if the script is read again in a loop. The other difference is that *string* performs variable substitution even if the string parameter is quoted.

For the *format* style, an equal-style variable is specified along with a C-style format string, e.g. “%f” or “%.10g”, which must be appropriate for formatting a double-precision floating-point value. The default format is “%.15g”. This variable style allows an equal-style variable to be formatted precisely when it is evaluated.

Note that if you simply wish to print a variable value with desired precision to the screen or logfile via the `print` or `fix print` commands, you can also do this by specifying an “immediate” variable with a trailing colon and format string, as part of the string argument of those commands. This is explained on the *Commands parse* doc page.

For the *getenv* style, a single string is assigned to the variable which should be the name of an environment variable. When the variable is evaluated, it returns the value of the environment variable, or an empty string if it not defined. This style of variable can be used to adapt the behavior of LAMMPS input scripts via environment variable settings, or to retrieve information that has been previously stored with the `shell putenv` command. Note that because environment variable settings are stored by the operating systems, they persist beyond a `clear` command.

For the *file* style, a filename is provided which contains a list of strings to assign to the variable, one per line. The strings can be numeric values if desired. See the discussion of the `next()` function below for equal-style variables, which will convert the string of a file-style variable into a numeric value in a formula.

When a file-style variable is defined, the file is opened and the string on the first line is read and stored with the variable. This means the variable can then be evaluated as many times as desired and will return that string. There are two ways to cause the next string from the file to be read: use the `next` command or the `next()` function in an equal- or atom-style variable, as discussed below.

The rules for formatting the file are as follows. A comment character “#” can be used anywhere on a line; text starting with the comment character is stripped. Blank lines are skipped. The first “word” of a non-blank line, delimited by white-space, is the “string” assigned to the variable.

For the *atomfile* style, a filename is provided which contains one or more sets of values, to assign on a per-atom basis to the variable. The format of the file is described below.

When an atomfile-style variable is defined, the file is opened and the first set of per-atom values are read and stored with the variable. This means the variable can then be evaluated as many times as desired and will return those values. There are two ways to cause the next set of per-atom values from the file to be read: use the `next` command or the `next()` function in an atom-style variable, as discussed below.
The rules for formatting the file are as follows. Each time a set of per-atom values is read, a non-blank line is searched for in the file. The file is read line by line but only up to 254 characters are used. The rest are ignored. A comment character “#” can be used anywhere on a line and all text following and the “#” character are ignored; text starting with the comment character is stripped. Blank lines are skipped. The first “word” of a non-blank line, delimited by white-space, is read as the count $N$ of per-atom lines to immediately follow. $N$ can be the total number of atoms in the system, or only a subset. The next $N$ lines have the following format

| ID | value |

where ID is an atom ID and value is the per-atom numeric value that will be assigned to that atom. IDs can be listed in any order.

**Note:** Every time a set of per-atom lines is read, the value for all atoms is first set to 0.0. Thus values for atoms whose ID does not appear in the set, will remain 0.0.

For the *python* style a Python function name is provided. This needs to match a function name specified in a *python* command which returns a value to this variable as defined by its *return* keyword. For example these two commands would be self-consistent:

```
variable foo python myMultiply
python myMultiply return v_foo format f file funcs.py
```

The two commands can appear in either order so long as both are specified before the Python function is invoked for the first time.

Each time the variable is evaluated, the associated Python function is invoked, and the value it returns is also returned by the variable. Since the Python function can use other LAMMPS variables as input, or query internal LAMMPS quantities to perform its computation, this means the variable can return a different value each time it is evaluated.

The type of value stored in the variable is determined by the *format* keyword of the *python* command. It can be an integer (i), floating point (f), or string (s) value. As mentioned above, if it is a numeric value (integer or floating point), then the python-style variable can be used in place of an equal-style variable anywhere in an input script, e.g. as an argument to another command that allows for equal-style variables.

For the *timer* style no additional argument is specified. The value of the variable is set by querying the current elapsed wall time of the simulation. This is done at the point in time when the variable is defined in the input script. If a second timer-style variable is also defined, then a simple formula can be used to calculate the elapsed time between the two timers, as in the example at the top of this manual entry. As mentioned above, timer-style variables can be redefined elsewhere in the input script, so the same pair of variables can be used in a loop or to time a series of operations.

For the *internal* style a numeric value is provided. This value will be assigned to the variable until a LAMMPS command sets it to a new value. There are currently only two LAMMPS commands that require *internal* variables as inputs, because they reset them: *create_atoms* and *fix controller*. As mentioned above, an internal-style variable can be used in place of an equal-style variable anywhere else in an input script, e.g. as an argument to another command that allows for equal-style variables.

For the *equal* and *vector* and *atom* styles, a single string is specified which represents a formula that will be evaluated afresh each time the variable is used. If you want spaces in the string, enclose it in double quotes so the parser will treat it as a single argument. For *equal*-style variables the formula computes a scalar quantity, which becomes the value of the variable whenever it is evaluated. For *vector*-style variables the formula must compute a vector of quantities, which becomes the value of the variable whenever it is evaluated. The calculated vector can be of length one, but it cannot be a simple scalar value like that produced by an equal-style compute. I.e. the formula for a vector-style variable must have at least one quantity in it that refers to a global vector produced by a compute, fix, or other vector-style variable. For *atom*-style variables the formula computes one quantity for each atom whenever it is evaluated.
Note that equal, vector, and atom variables can produce different values at different stages of the input script or at different times during a run. For example, if an equal variable is used in a fix print command, different values could be printed each timestep it was invoked. If you want a variable to be evaluated immediately, so that the result is stored by the variable instead of the string, see the section below on “Immediate Evaluation of Variables”.

The next command cannot be used with equal or vector or atom style variables, since there is only one string.

The formula for an equal, vector, or atom variable can contain a variety of quantities. The syntax for each kind of quantity is simple, but multiple quantities can be nested and combined in various ways to build up formulas of arbitrary complexity. For example, this is a valid (though strange) variable formula:

```
variable x equal "pe + c_MyTemp / vol^(1/3)"
```

Specifically, a formula can contain numbers, constants, thermo keywords, math operators, math functions, group functions, region functions, atom values, atom vectors, compute references, fix references, and references to other variables.
Most of the formula elements produce a scalar value. Some produce a global or per-atom vector of values. Global vectors can be produced by computes or fixes or by other vector-style variables. Per-atom vectors are produced by atom vectors, compute references that represent a per-atom vector, fix references that represent a per-atom vector, and variables that are atom-style variables. Math functions that operate on scalar values produce a scalar value; math function that operate on global or per-atom vectors do so element-by-element and produce a global or per-atom vector.

A formula for equal-style variables cannot use any formula element that produces a global or per-atom vector. A formula for a vector-style variable can use formula elements that produce either a scalar value or a global vector value, but cannot use a formula element that produces a per-atom vector. A formula for an atom-style variable can use formula elements that produce either a scalar value or a per-atom vector, but not one that produces a global vector. Atom-style variables are evaluated by other commands that define a group on which they operate, e.g. a dump or compute or fix command. When they invoke the atom-style variable, only atoms in the group are included in the formula evaluation.
The variable evaluates to 0.0 for atoms not in the group.

**Numbers, constants, and thermo keywords**

Numbers can contain digits, scientific notation (3.0e20, 3.0e-20, 3.0E20, 3.0E-20), and leading minus signs.

Constants are set at compile time and cannot be changed. $PI$ will return the number 3.14159265358979323846; $on$, $true$ or $yes$ will return 1.0; $off$, $false$ or $no$ will return 0.0; $version$ will return a numeric version code of the current LAMMPS version (e.g. version 2 Sep 2015 will return the number 20150902). The corresponding value for newer versions of LAMMPS will be larger, for older versions of LAMMPS will be smaller. This can be used to have input scripts adapt automatically to LAMMPS versions, when non-backwards compatible syntax changes are introduced. Here is an illustrative example (which will not work, since the $version$ has been introduced more recently):

```bash
if $(version<20140513) then "communicate vel yes" else "comm_modify vel yes"
```

The thermo keywords allowed in a formula are those defined by the `thermo_style custom` command. Thermo keywords that require a `compute` to calculate their values such as “temp” or “press”, use computes stored and invoked by the `thermo_style` command. This means that you can only use those keywords in a variable if the style you are using with the thermo_style command (and the thermo keywords associated with that style) also define and use the needed compute. Note that some thermo keywords use a compute indirectly to calculate their value (e.g. the enthalpy keyword uses temp, pe, and pressure). If a variable is evaluated directly in an input script (not during a run), then the values accessed by the thermo keyword must be current. See the discussion below about “Variable Accuracy”.

**Math Operators**

Math operators are written in the usual way, where the “x” and “y” in the examples can themselves be arbitrarily complex formulas, as in the examples above. In this syntax, “x” and “y” can be scalar values or per-atom vectors. For example, “ke/natoms” is the division of two scalars, where “vy+vz” is the element-by-element sum of two per-atom vectors of y and z velocities.

Operators are evaluated left to right and have the usual C-style precedence: unary minus and unary logical NOT operator “!” have the highest precedence, exponentiation “^” is next; multiplication and division and the modulo operator “%” are next; addition and subtraction are next; the 4 relational operators “<”, “<=”, “>”, and “>=” are next; the two remaining relational operators “==” and “!”=” are next; then the logical AND operator “&&”; and finally the logical OR operator “||” and logical XOR (exclusive or) operator “|” have the lowest precedence. Parenthesis can be used to group one or more portions of a formula and/or enforce a different order of evaluation than what would occur with the default precedence.

**Note:** Because a unary minus is higher precedence than exponentiation, the formula “-2^2” will evaluate to 4, not -4. This convention is compatible with some programming languages, but not others. As mentioned, this behavior can be easily overridden with parenthesis; the formula “-(2^2)” will evaluate to -4.

The 6 relational operators return either a 1.0 or 0.0 depending on whether the relationship between x and y is TRUE or FALSE. For example the expression x<10.0 in an atom-style variable formula will return 1.0 for all atoms whose x-coordinate is less than 10.0, and 0.0 for the others. The logical AND operator will return 1.0 if both its arguments are non-zero, else it returns 0.0. The logical OR operator will return 1.0 if either of its arguments is non-zero, else it returns 0.0. The logical XOR operator will return 1.0 if one of its arguments is zero and the other non-zero, else it returns 0.0. The logical NOT operator returns 1.0 if its argument is 0.0, else it returns 0.0.
These relational and logical operators can be used as a masking or selection operation in a formula. For example, the number of atoms whose properties satisfy one or more criteria could be calculated by taking the returned per-atom vector of ones and zeroes and passing it to the compute reduce command.

Math Functions

Math functions are specified as keywords followed by one or more parenthesized arguments “x”, “y”, “z”, each of which can themselves be arbitrarily complex formulas. In this syntax, the arguments can represent scalar values or global vectors or per-atom vectors. In the latter case, the math operation is performed on each element of the vector. For example, “sqrt(natoms)” is the sqrt() of a scalar, where “sqrt(y*z)” yields a per-atom vector with each element being the sqrt() of the product of one atom’s y and z coordinates.

Most of the math functions perform obvious operations. The ln() is the natural log; log() is the base 10 log.

The random(x,y,z) function takes 3 arguments: x = lo, y = hi, and z = seed. It generates a uniform random number between lo and hi. The normal(x,y,z) function also takes 3 arguments: x = mu, y = sigma, and z = seed. It generates a Gaussian variate centered on mu with variance sigma^2. In both cases the seed is used the first time the internal random number generator is invoked, to initialize it. For equal-style and vector-style variables, every processor uses the same seed so that they each generate the same sequence of random numbers. For atom-style variables, a unique seed is created for each processor, based on the specified seed. This effectively generates a different random number for each atom being looped over in the atom-style variable.

Note: Internally, there is just one random number generator for all equal-style and vector-style variables and another one for all atom-style variables. If you define multiple variables (of each style) which use the random() or normal() math functions, then the internal random number generators will only be initialized once, which means only one of the specified seeds will determine the sequence of generated random numbers.

The ceil(), floor(), and round() functions are those in the C math library. Ceil() is the smallest integer not less than its argument. Floor() if the largest integer not greater than its argument. Round() is the nearest integer to its argument.

The ramp(x,y) function uses the current timestep to generate a value linearly interpolated between the specified x,y values over the course of a run, according to this formula:

\[ \text{value} = x + (y-x) \times \frac{\text{timestep}-\text{startstep}}{\text{stopstep}-\text{startstep}} \]

The run begins on startstep and ends on stopstep. Startstep and stopstep can span multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

The stagger(x,y) function uses the current timestep to generate a new timestep. X,y > 0 and x > y are required. The generated timesteps increase in a staggered fashion, as the sequence x,x+y,2x,2x+y,3x,3x+y,etc. For any current timestep, the next timestep in the sequence is returned. Thus if stagger(1000,100) is used in a variable by the dump_modify every command, it will generate the sequence of output timesteps:

100,1000,1100,2000,2100,3000,etc

The logfreq(x,y,z) function uses the current timestep to generate a new timestep. X,y,z > 0 and y < z are required. The generated timesteps are on a base-z logarithmic scale, starting with x, and the y value is how many of the z-1 possible timesteps within one logarithmic interval are generated. I.e. the timesteps follow the sequence x,2x,3x,...y*x,x*z,2x*z,3x*z,...y*x*z,x*z^2,2x*z^2,etc. For any current timestep, the next timestep in the sequence is returned. Thus if logfreq(100,4,10) is used in a variable by the dump_modify every command, it will generate this sequence of output timesteps:

100,200,300,400,1000,2000,3000,4000,10000,20000,etc
The logfreq2(x,y,z) function is similar to logfreq, except a single logarithmic interval is divided into y equally-spaced timesteps and all of them are output. Y < z is not required. Thus, if logfreq2(100,18,10) is used in a variable by the dump_modify every command, then the interval between 100 and 1000 is divided as 900/18 = 50 steps, and it will generate the sequence of output timesteps:

100,150,200,...950,1000,1500,2000,...9500,10000,15000,etc

The logfreq3(x,y,z) function generates y points between x and z (inclusive), that are separated by a multiplicative ratio: (z/x)^((1/(y-1))). Constraints are: x,z > 0, y > 1, z-x >= y-1. For eg., if logfreq3(10,25,1000) is used in a variable by the fix print command, then the interval between 10 and 1000 is divided into 24 parts with a multiplicative separation of ~1.21, and it will generate the following sequence of output timesteps:

10, 13, 15, 18, 22, 27, 32,...384, 465, 563, 682, 826, 1000

The stride(x,y,z) function uses the current timestep to generate a new timestep. X,y >= 0 and z > 0 and x <= y are required. The generated timesteps increase in increments of z, from x to y, i.e. it generates the sequence x,x+z,x+2z,...,y. If y-x is not a multiple of z, then similar to the way a for loop operates, the last value will be one that does not exceed y. For any current timestep, the next timestep in the sequence is returned. Thus if stride(1000,2000,100) is used in a variable by the dump_modify every command, it will generate the sequence of output timesteps:

1000,1100,1200, ..., 1900,2000

The stride2(x,y,z,a,b,c) function is similar to the stride() function except it generates two sets of strided timesteps, one at a coarser level and one at a finer level. Thus it is useful for debugging, e.g. to produce output every timestep at the point in simulation when a problem occurs. X,y >= 0 and z > 0 and x <= y are required, as are a,b >= 0 and c > 0 and a < b. Also, a >= x and b <= y are required so that the second stride is inside the first. The generated timesteps increase in increments of z, starting at x, until a is reached. At that point the timestep increases in increments of c, from a to b, then after b, increments by z are resumed until y is reached. For any current timestep, the next timestep in the sequence is returned. Thus if stride2(1000,2000,100,1350,1360,1) is used in a variable by the dump_modify every command, it will generate the sequence of output timesteps:

1000,1100,1200,1300,1350,1351,1352, ..., 1359,1360,1400,1500, ..., 2000

The vdisplace(x,y) function takes 2 arguments: x = value0 and y = velocity, and uses the elapsed time to change the value by a linear displacement due to the applied velocity over the course of a run, according to this formula:

value = value0 + velocity*(timestep-startstep)*dt

where dt = the timestep size.

The run begins on startstep. Startstep can span multiple runs, using the start keyword of the run command. See the run command for details of how to do this. Note that the thermo_style keyword elaplong = timestep-startstep.

The swiggle(x,y,z) and cwiggle(x,y,z) functions each take 3 arguments: x = value0, y = amplitude, z = period. They use the elapsed time to oscillate the value by a sin() or cos() function over the course of a run, according to one of these formulas, where omega = 2 PI / period:

value = value0 + Amplitude * sin(omega*(timestep-startstep)*dt)
value = value0 + Amplitude * (1 - cos(omega*(timestep-startstep)*dt))

where dt = the timestep size.

The run begins on startstep. Startstep can span multiple runs, using the start keyword of the run command. See the run command for details of how to do this. Note that the thermo_style keyword elaplong = timestep-startstep.
Group and Region Functions

Group functions are specified as keywords followed by one or two parenthesized arguments. The first argument ID is the group-ID. The dim argument, if it exists, is x or y or z. The dir argument, if it exists, is xmin, xmax, ymin, ymax, zmin, or zmax. The dindim argument, if it exists, is xx or yy or zz or xy or yz or xz.

The group function count() is the number of atoms in the group. The group functions mass() and charge() are the total mass and charge of the group. Xcm() and vcm() return components of the position and velocity of the center of mass of the group. Fcm() returns a component of the total force on the group of atoms. Bound() returns the min/max of a particular coordinate for all atoms in the group. Gyration() computes the radius-of-gyration of the group of atoms. See the compute gyration command for a definition of the formula. Angmom() returns components of the angular momentum of the group of atoms around its center of mass. Torque() returns components of the torque on the group of atoms around its center of mass, based on current forces on the atoms. Inertia() returns one of 6 components of the symmetric inertia tensor of the group of atoms around its center of mass, ordered as Ixx,Iyy,Izz,Ixy,Iyz,Ixz. Omega() returns components of the angular velocity of the group of atoms around its center of mass.

Region functions are specified exactly the same way as group functions except they take an extra final argument IDR which is the region ID. The function is computed for all atoms that are in both the group and the region. If the group is “all”, then the only criteria for atom inclusion is that it be in the region.

Special Functions

Special functions take specific kinds of arguments, meaning their arguments cannot be formulas themselves.

The sum(x), min(x), max(x), ave(x), trap(x), and slope(x) functions each take 1 argument which is of the form “c_ID” or “c_ID[N]” or “f_ID” or “f_ID[N]” or “v_name”. The first two are computes and the second two are fixes; the ID in the reference should be replaced by the ID of a compute or fix defined elsewhere in the input script. The compute or fix must produce either a global vector or array. If it produces a global vector, then the notation without “[N]” should be used. If it produces a global array, then the notation with “[N]” should be used, when N is an integer, to specify which column of the global array is being referenced. The last form of argument “v_name” is for a vector-style variable where “name” is replaced by the name of the variable.

These functions operate on a global vector of inputs and reduce it to a single scalar value. This is analogous to the operation of the compute reduce command, which performs similar operations on per-atom and local vectors.

The sum() function calculates the sum of all the vector elements. The min() and max() functions find the minimum and maximum element respectively. The ave() function is the same as sum() except that it divides the result by the length of the vector.

The trap() function is the same as sum() except the first and last elements are multiplied by a weighting factor of 1/2 when performing the sum. This effectively implements an integration via the trapezoidal rule on the global vector of data. I.e. consider a set of points, equally spaced by 1 in their x coordinate: (1,V1), (2,V2), ..., (N,VN), where the Vi are the values in the global vector of length N. The integral from 1 to N of these points is trap(). When appropriately normalized by the timestep size, this function is useful for calculating integrals of time-series data, like that generated by the fix ave/correlate command.

The slope() function uses linear regression to fit a line to the set of points, equally spaced by 1 in their x coordinate: (1,V1), (2,V2), ..., (N,VN), where the Vi are the values in the global vector of length N. The returned value is the slope of the line. If the line has a single point or is vertical, it returns 1.0e20.

The gmask(x) function takes 1 argument which is a group ID. It can only be used in atom-style variables. It returns a 1 for atoms that are in the group, and a 0 for atoms that are not.

The rmask(x) function takes 1 argument which is a region ID. It can only be used in atom-style variables. It returns a 1 for atoms that are in the geometric region, and a 0 for atoms that are not.
The grmask(x,y) function takes 2 arguments. The first is a group ID, and the second is a region ID. It can only be used in atom-style variables. It returns a 1 for atoms that are in both the group and region, and a 0 for atoms that are not in both.

The next(x) function takes 1 argument which is a variable ID (not “v_foo”, just “foo”). It must be for a file-style or atomfile-style variable. Each time the next() function is invoked (i.e. each time the equal-style or atom-style variable is evaluated), the following steps occur.

For file-style variables, the current string value stored by the file-style variable is converted to a numeric value and returned by the function. And the next string value in the file is read and stored. Note that if the line previously read from the file was not a numeric string, then it will typically evaluate to 0.0, which is likely not what you want.

For atomfile-style variables, the current per-atom values stored by the atomfile-style variable are returned by the function. And the next set of per-atom values in the file is read and stored.

Since file-style and atomfile-style variables read and store the first line of the file or first set of per-atoms values when they are defined in the input script, these are the value(s) that will be returned the first time the next() function is invoked. If next() is invoked more times than there are lines or sets of lines in the file, the variable is deleted, similar to how the next command operates.

The is_file(name) function is a test whether name is a (readable) file and returns 1 in this case, otherwise it returns 0. For that name is taken as a literal string and must not have any blanks in it.

The extract_setting(name) function enables access to basic settings for the LAMMPS executable and the running simulation via calling the lammps_extract_setting() library function. For example, the number of processors (MPI ranks) being used by the simulation or the MPI process ID (for this processor) can be queried, or the number of atom types, bond types and so on. For the full list of available keywords name and their meaning, see the documentation for extract_setting() via the link in this paragraph.

**Feature Functions**

Feature functions allow to probe the running LAMMPS executable for whether specific features are either active, defined, or available. The functions take two arguments, a category and a corresponding argument. The arguments are strings and thus cannot be formulas themselves; only $-style immediate variable expansion is possible. Return value is either 1.0 or 0.0 depending on whether the function evaluates to true or false, respectively.

The is_active(category,feature) function allows to query for active settings which are grouped by categories. Currently supported categories and arguments are:

- **package**: argument = gpu or intel or kokkos or omp
- **newton**: argument = pair or bond or any
- **pair**: argument = single or respa or manybody or tail or shift
- **comm_style**: argument = brick or tiled
- **min_style**: argument = any of the compiled in minimizer styles
- **run_style**: argument = any of the compiled in run styles
- **atom_style**: argument = any of the compiled in atom style
- **pair_style**: argument = any of the compiled in pair styles
- **bond_style**: argument = any of the compiled in bond styles
- **angle_style**: argument = any of the compiled in angle styles
- **dihedral_style**: argument = any of the compiled in dihedral styles
• improper_style: argument = any of the compiled in improper styles
• kspace_style: argument = any of the compiled in kspace styles

Most of the settings are self-explanatory, the single argument in the pair category allows to check whether a pair style supports a Pair::single() function as needed by compute group/group and others features or LAMMPS, respa allows to check whether the inner/middle/outer mode of r-RESPA is supported. In the various style categories, the checking is also done using suffix flags, if available and enabled.

Example 1: disable use of suffix for pppm when using GPU package (i.e. run it on the CPU concurrently to running the pair style on the GPU), but do use the suffix otherwise (e.g. with OPENMP).

```
pair_style lj/cut/coul/long 14.0
if $(is_active(package,gpu)) then "suffix off"
kspace_style pppm
```

Example 2: use r-RESPA with inner/outer cutoff, if supported by pair style, otherwise fall back to using pair and reducing the outer time step

```
timestep $(2.0*(1.0+2.0*is_active(pair,respa))
if $(is_active(pair,respa)) then "run_style respa 4 3 2 improper 1 inner 2 5.5 7.0
ught 3 kspace 4" else "run_style respa 3 3 2 improper 1 pair 2 kspace 3"
```

The is_available(category,name) function allows to query whether a specific optional feature is available, i.e. compiled in. This currently works for the following categories: command, compute, fix, pair_style and feature. For all categories except command and feature also appending active suffixes is tried before reporting failure.

The feature category is used to check the availability of compiled in features such as GZIP support, PNG support, JPEG support, FFMPEG support, and C++ exceptions for error handling. Corresponding values for name are gzip, png, jpeg, ffmpeg and exceptions.

This enables writing input scripts which only dump using a given format if the compiled binary supports it.

```
if "$(is_available(feature,png))" then "print 'PNG supported'" else "print 'PNG not supported"

if "$(is_available(feature,ffmpeg)" then "dump 3 all movie 25 movie.mp4 type type zoom 1.
6 adiam 1.0"
```

The is_defined(category,id) function allows to query categories like compute, dump, fix, group, region, and variable whether an entry with the provided name or id is defined.

## Atom Values and Vectors

Atom values take an integer argument I from 1 to N, where I is the atom-ID, e.g. x[243], which means use the x coordinate of the atom with ID = 243. Or they can take a variable name, specified as v_name, where name is the name of the variable, like x[v_myIndex]. The variable can be of any style except vector or atom or atomfile variables. The variable is evaluated and the result is expected to be numeric and is cast to an integer (i.e. 3.4 becomes 3), to use an index, which must be a value from 1 to N. Note that a “formula” cannot be used as the argument between the brackets, e.g. x[243+10] or x[v_myIndex+1] are not allowed. To do this a single variable can be defined that contains the needed formula.

Note that the 0 < atom-ID <= N, where N is the largest atom ID in the system. If an ID is specified for an atom that does not currently exist, then the generated value is 0.0.
Atom vectors generate one value per atom, so that a reference like “vx” means the x-component of each atom’s velocity will be used when evaluating the variable.

The meaning of the different atom values and vectors is mostly self-explanatory. *Mol* refers to the molecule ID of an atom, and is only defined if an *atom_style* is being used that defines molecule IDs.

Note that many other atom attributes can be used as inputs to a variable by using the *compute property/atom* command and then specifying a quantity from that compute.

---

**Compute References**

Compute references access quantities calculated by a *compute*. The ID in the reference should be replaced by the ID of a compute defined elsewhere in the input script. As discussed in the page for the *compute* command, computes can produce global, per-atom, or local values. Only global and per-atom values can be used in a variable. Computes can also produce a scalar, vector, or array.

An equal-style variable can only use scalar values, which means a global scalar, or an element of a global or per-atom vector or array. A vector-style variable can use scalar values or a global vector of values, or a column of a global array of values. Atom-style variables can use global scalar values. They can also use per-atom vector values, or a column of a per-atom array. See the doc pages for individual computes to see what kind of values they produce.

Examples of different kinds of compute references are as follows. There is typically no ambiguity (see exception below) as to what a reference means, since computes only produce either global or per-atom quantities, never both.

<table>
<thead>
<tr>
<th>Reference</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>c_ID</td>
<td>global scalar, or per-atom vector</td>
</tr>
<tr>
<td>c_ID[I]</td>
<td>Ith element of global vector, or atom I’s value in per-atom vector, or Ith column from per-atom array</td>
</tr>
<tr>
<td>c_ID[I][J]</td>
<td>I,J element of global array, or atom I’s Jth value in per-atom array</td>
</tr>
</tbody>
</table>

For I and J indices, integers can be specified or a variable name, specified as v_name, where name is the name of the variable. The rules for this syntax are the same as for the “Atom Values and Vectors” discussion above.

One source of ambiguity for compute references is when a vector-style variable refers to a compute that produces both a global scalar and a global vector. Consider a compute with ID “foo” that does this, referenced as follows by variable “a”, where “myVec” is another vector-style variable:

```
variable a vector c_foo*v_myVec
```

The reference “c_foo” could refer to either the global scalar or global vector produced by compute “foo”. In this case, “c_foo” will always refer to the global scalar, and “C_foo” can be used to reference the global vector. Similarly if the compute produces both a global vector and global array, then “c_foo[I]” will always refer to an element of the global vector, and “C_foo[I]” can be used to reference the Ith column of the global array.

Note that if a variable containing a compute is evaluated directly in an input script (not during a run), then the values accessed by the compute must be current. See the discussion below about “Variable Accuracy”.

---

16.135. *variable command* 1035
Fix References

Fix references access quantities calculated by a \textit{fix}. The ID in the reference should be replaced by the ID of a fix defined elsewhere in the input script. As discussed in the page for the \textit{fix} command, fixes can produce global, per-atom, or local values. Only global and per-atom values can be used in a variable. Fixes can also produce a scalar, vector, or array. An equal-style variable can only use scalar values, which means a global scalar, or an element of a global or per-atom vector or array. Atom-style variables can use the same scalar values. They can also use per-atom vector values. A vector value can be a per-atom vector itself, or a column of an per-atom array. See the doc pages for individual fixes to see what kind of values they produce.

The different kinds of fix references are exactly the same as the compute references listed in the above table, where “c_” is replaced by “f_”. Again, there is typically no ambiguity (see exception below) as to what a reference means, since fixes only produce either global or per-atom quantities, never both.

| f_{ID} | global scalar, or per-atom vector |
| f_{ID}[I] | Ith element of global vector, or atom I’s value in per-atom vector, or Ith column from per-atom array |
| f_{ID}[I][J] | I,J element of global array, or atom I’s Jth value in per-atom array |

For I and J indices, integers can be specified or a variable name, specified as v\_name, where name is the name of the variable. The rules for this syntax are the same as for the “Atom Values and Vectors” discussion above.

One source of ambiguity for fix references is the same ambiguity discussed for compute references above. Namely when a vector-style variable refers to a fix that produces both a global scalar and a global vector. The solution is the same as for compute references. For a fix with ID “foo”, “f\_foo” will always refer to the global scalar, and “F\_foo” can be used to reference the global vector. And similarly for distinguishing between a fix’s global vector versus global array with “f\_foo[I]” versus “F\_foo[I]”.

Note that if a variable containing a fix is evaluated directly in an input script (not during a run), then the values accessed by the fix should be current. See the discussion below about “Variable Accuracy”.

Note that some fixes only generate quantities on certain timesteps. If a variable attempts to access the fix on non-allowed timesteps, an error is generated. For example, the \textit{fix ave/time} command may only generate averaged quantities every 100 steps. See the doc pages for individual fix commands for details.

Variable References

Variable references access quantities stored or calculated by other variables, which will cause those variables to be evaluated. The name in the reference should be replaced by the name of a variable defined elsewhere in the input script.

As discussed on this doc page, equal-style variables generate a single global numeric value, vector-style variables generate a vector of global numeric values, and atom-style and atomfile-style variables generate a per-atom vector of numeric values. All other variables store one or more strings.

The formula for an equal-style variable can use any style of variable including a vector\_style or atom\_style or atomfile\_style. For these 3 styles, a subscript must be used to access a single value from the vector-, atom-, or atomfile-style variable. If a string-storing variable is used, the string is converted to a numeric value. Note that this will typically produce a 0.0 if the string is not a numeric string, which is likely not what you want.

The formula for a vector-style variable can use any style of variable, including atom\_style or atomfile\_style variables. For these 2 styles, a subscript must be used to access a single value from the atom-, or atomfile-style variable.

The formula for an atom-style variable can use any style of variable, including other atom\_style or atomfile\_style variables. If it uses a vector\_style variable, a subscript must be used to access a single value from the vector\_style variable.
Examples of different kinds of variable references are as follows. There is no ambiguity as to what a reference means, since variables produce only a global scalar or global vector or per-atom vector.

<table>
<thead>
<tr>
<th>v_name</th>
<th>global scalar from equal-style variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_name</td>
<td>global vector from vector-style variable</td>
</tr>
<tr>
<td>v_name</td>
<td>per-atom vector from atom-style or atomfile-style variable</td>
</tr>
<tr>
<td>v_name[I]</td>
<td>Ith element of a global vector from vector-style variable</td>
</tr>
<tr>
<td>v_name[I]</td>
<td>value of atom with ID = I from atom-style or atomfile-style variable</td>
</tr>
</tbody>
</table>

For the I index, an integer can be specified or a variable name, specified as v_name, where name is the name of the variable. The rules for this syntax are the same as for the “Atom Values and Vectors” discussion above.

### 16.135.4 Immediate Evaluation of Variables

If you want an equal-style variable to be evaluated immediately, it may be the case that you do not need to define a variable at all. See the *Commands parse* page for info on how to use “immediate” variables in an input script, specified as $(formula)$ with parenthesis, where the formula has the same syntax as equal-style variables described on this page. This effectively evaluates a formula immediately without using the variable command to define a named variable.

More generally, there is a difference between referencing a variable with a leading $ sign (e.g. $x or ${abc}) versus with a leading “v_” (e.g. v_x or v_abc). The former can be used in any input script command, including a variable command. The input script parser evaluates the reference variable immediately and substitutes its value into the command. As explained on the *Commands parse* doc page, you can also use un-named “immediate” variables for this purpose. For example, a string like this $(xlo+xhi)/2+sqrt(v_area)) in an input script command evaluates the string between the parenthesis as an equal-style variable formula.

Referencing a variable with a leading “v_” is an optional or required kind of argument for some commands (e.g. the fix ave/chunk or dump custom or thermo_style commands) if you wish it to evaluate a variable periodically during a run. It can also be used in a variable formula if you wish to reference a second variable. The second variable will be evaluated whenever the first variable is evaluated.

As an example, suppose you use this command in your input script to define the variable “v” as

```plaintext
variable v equal vol
```

before a run where the simulation box size changes. You might think this will assign the initial volume to the variable “v”. That is not the case. Rather it assigns a formula which evaluates the volume (using the thermo_style keyword “vol”) to the variable “v”. If you use the variable “v” in some other command like fix ave/time then the current volume of the box will be evaluated continuously during the run.

If you want to store the initial volume of the system, you can do it this way:

```plaintext
variable v equal vol
variable v0 equal $v
```

The second command will force “v” to be evaluated (yielding the initial volume) and assign that value to the variable “v0”. Thus the command

```plaintext
thermo_style custom step v_v v_v0
```

would print out both the current and initial volume periodically during the run.

Note that it is a mistake to enclose a variable formula in double quotes if it contains variables preceded by $ signs. For example,
This is because the quotes prevent variable substitution (explained on the Commands parse doc page), and thus an error will occur when the formula for “vratio” is evaluated later.

### 16.135.5 Variable Accuracy

Obviously, LAMMPS attempts to evaluate variables containing formulas (equal and atom style variables) accurately whenever the evaluation is performed. Depending on what is included in the formula, this may require invoking a compute, either directly or indirectly via a thermo keyword, or accessing a value previously calculated by a compute, or accessing a value calculated and stored by a fix. If the compute is one that calculates the pressure or energy of the system, then these quantities need to be tallied during the evaluation of the interatomic potentials (pair, bond, etc) on timesteps that the variable will need the values.

LAMMPS keeps track of all of this during a run or energy minimization. An error will be generated if you attempt to evaluate a variable on timesteps when it cannot produce accurate values. For example, if a thermo_style custom command prints a variable which accesses values stored by a fix ave/time command and the timesteps on which thermo output is generated are not multiples of the averaging frequency used in the fix command, then an error will occur.

An input script can also request variables be evaluated before or after or in between runs, e.g. by including them in a print command. In this case, if a compute is needed to evaluate a variable (either directly or indirectly), LAMMPS will not invoke the compute, but it will use a value previously calculated by the compute, and can do this only if it was invoked on the current timestep. Fixes will always provide a quantity needed by a variable, but the quantity may or may not be current. This leads to one of three kinds of behavior:

1. The variable may be evaluated accurately. If it contains references to a compute or fix, and these values were calculated on the last timestep of a preceding run, then they will be accessed and used by the variable and the result will be accurate.

2. LAMMPS may not be able to evaluate the variable and will generate an error message stating so. For example, if the variable requires a quantity from a compute that has not been invoked on the current timestep, LAMMPS will generate an error. This means, for example, that such a variable cannot be evaluated before the first run has occurred. Likewise, in between runs, a variable containing a compute cannot be evaluated unless the compute was invoked on the last timestep of the preceding run, e.g. by thermodynamic output.

One way to get around this problem is to perform a 0-timestep run before using the variable. For example, these commands

```
variable t equal temp
print "Initial temperature = $t"
run 1000
```

will generate an error if the run is the first run specified in the input script, because generating a value for the “t” variable requires a compute for calculating the temperature to be invoked.

However, this sequence of commands would be fine:

```
run 0
variable t equal temp
print "Initial temperature = $t"
run 1000
```

The 0-timestep run initializes and invokes various computes, including the one for temperature, so that the value it stores is current and can be accessed by the variable “t” after the run has completed. Note that a 0-timestep run does
not alter the state of the system, so it does not change the input state for the 1000-timestep run that follows. Also note that the 0-timestep run must actually use and invoke the compute in question (e.g. via \textit{thermo} or \textit{dump} output) in order for it to enable the compute to be used in a variable after the run. Thus if you are trying to print a variable that uses a compute you have defined, you can insure it is invoked on the last timestep of the preceding run by including it in thermodynamic output.

Unlike computes, \textit{fixes} will never generate an error if their values are accessed by a variable in between runs. They always return some value to the variable. However, the value may not be what you expect if the fix has not yet calculated the quantity of interest or it is not current. For example, the \textit{fix indent} command stores the force on the indenter. But this is not computed until a run is performed. Thus if a variable attempts to print this value before the first run, zeroes will be output. Again, performing a 0-timestep run before printing the variable has the desired effect.

(3) The variable may be evaluated incorrectly and LAMMPS may have no way to detect this has occurred. Consider the following sequence of commands:

```
pair_coeff 1 1 1.0 1.0
run 1000
pair_coeff 1 1 1.5 1.0
variable e equal pe
print "Final potential energy = $e"
```

The first run is performed using one setting for the pairwise potential defined by the \textit{pair_style} and \textit{pair_coeff} commands. The potential energy is evaluated on the final timestep and stored by the \textit{compute pe} compute (this is done by the \textit{thermo_style} command). Then a pair coefficient is changed, altering the potential energy of the system. When the potential energy is printed via the “e” variable, LAMMPS will use the potential energy value stored by the \textit{compute pe} compute, thinking it is current. There are many other commands which could alter the state of the system between runs, causing a variable to evaluate incorrectly.

The solution to this issue is the same as for case (2) above, namely perform a 0-timestep run before the variable is evaluated to insure the system is up-to-date. For example, this sequence of commands would print a potential energy that reflected the changed pairwise coefficient:

```
pair_coeff 1 1 1.0 1.0
run 1000
pair_coeff 1 1 1.5 1.0
run 0
variable e equal pe
print "Final potential energy = $e"
```

16.135.6 Restrictions

Indexing any formula element by global atom ID, such as an atom value, requires the \textit{atom style} to use a global mapping in order to look up the vector indices. By default, only atom styles with molecular information create global maps. The \textit{atom_modify map} command can override the default, e.g. for atomic-style atom styles.

All \textit{universe-} and \textit{uloop}-style variables defined in an input script must have the same number of values.

velocity all zero linear
```

16.136.3 Description

Set or change the velocities of a group of atoms in one of several styles. For each style, there are required arguments and optional keyword/value parameters. Not all options are used by each style. Each option has a default as listed below.

The `create` style generates an ensemble of velocities using a random number generator with the specified seed at the specified temperature.

The `set` style sets the velocities of all atoms in the group to the specified values. If any component is specified as `NULL`, then it is not set. Any of the `vx, vy, vz` velocity components can be specified as an equal-style or atom-style variable. If the value is a variable, it should be specified as `v_name`, where name is the variable name. In this case, the variable will be evaluated, and its value used to determine the velocity component. Note that if a variable is used, the velocity it calculates must be in box units, not lattice units; see the discussion of the `units` keyword below.

Equal-style variables can specify formulas with various mathematical functions, and include `thermo_style` command keywords for the simulation box parameters or other parameters.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus it is easy to specify a spatially-dependent velocity field.

The `scale` style computes the current temperature of the group of atoms and then rescales the velocities to the specified temperature.

The `ramp` style is similar to that used by the `compute temp/ramp` command. Velocities ramped uniformly from `vlo` to `vhi` are applied to dimension `vx`, `vy`, or `vz`. The value assigned to a particular atom depends on its relative coordinate value (in `dim`) from `clo` to `chi`. For the example above, an atom with y-coordinate of 10 (1/4 of the way from 5 to 25), would be assigned a x-velocity of 1.25 (1/4 of the way from 0.0 to 5.0). Atoms outside the coordinate bounds (less than 5 or greater than 25 in this case), are assigned velocities equal to `vlo` or `vhi` (0.0 or 5.0 in this case).

The `zero` style adjusts the velocities of the group of atoms so that the aggregate linear or angular momentum is zero. No other changes are made to the velocities of the atoms. If the `rigid` option is specified (see below), then the zeroing is performed on individual rigid bodies, as defined by the `fix rigid` or `fix rigid/small` commands. In other words, zero linear will set the linear momentum of each rigid body to zero, and zero angular will set the angular momentum of each rigid body to zero. This is done by adjusting the velocities of the atoms in each rigid body.

All temperatures specified in the velocity command are in temperature units; see the `units` command. The units of velocities and coordinates depend on whether the `units` keyword is set to `box` or `lattice`, as discussed below.

For all styles, no atoms are assigned z-component velocities if the simulation is 2d; see the `dimension` command.

The keyword/value options are used in the following ways by the various styles.

The `dist` keyword is used by `create`. The ensemble of generated velocities can be a uniform distribution from some minimum to maximum value, scaled to produce the requested temperature. Or it can be a gaussian distribution with a mean of 0.0 and a sigma scaled to produce the requested temperature.

The `sum` keyword is used by all styles, except `zero`. The new velocities will be added to the existing ones if `sum = yes`, or will replace them if `sum = no`.  

16.136. velocity command 1041
The *mom* and *rot* keywords are used by *create*. If *mom = yes*, the linear momentum of the newly created ensemble of velocities is zeroed; if *rot = yes*, the angular momentum is zeroed.

If specified, the *temp* keyword is used by *create* and *scale* to specify a *compute* that calculates temperature in a desired way, e.g. by first subtracting out a velocity bias, as discussed on the *How to thermostat* doc page. If this keyword is not specified, *create* and *scale* calculate temperature using a compute that is defined internally as follows:

```
compute velocity_temp group-ID temp
```

where group-ID is the same ID used in the velocity command, i.e. the group of atoms whose velocity is being altered. This compute is deleted when the velocity command is finished. See the *compute temp* command for details. If the calculated temperature should have degrees-of-freedom removed due to fix constraints (e.g. SHAKE or rigid-body constraints), then the appropriate fix command must be specified before the velocity command is issued.

The *bias* keyword with a *yes* setting is used by *create* and *scale*, but only if the *temp* keyword is also used to specify a *compute* that calculates temperature in a desired way. If the temperature compute also calculates a velocity bias, the bias is subtracted from atom velocities before the *create* and *scale* operations are performed. After the operations, the bias is added back to the atom velocities. See the *How to thermostat* page for more discussion of temperature computes with biases. Note that the velocity bias is only applied to atoms in the temperature compute specified with the *temp* keyword.

As an example, assume atoms are currently streaming in a flow direction (which could be separately initialized with the *ramp* style), and you wish to initialize their thermal velocity to a desired temperature. In this context thermal velocity means the per-particle velocity that remains when the streaming velocity is subtracted. This can be done using the *create* style with the *temp* keyword specifying the ID of a *compute temp/ramp* or *compute temp/profile* command, and the *bias* keyword set to a *yes* value.

The *loop* keyword is used by *create* in the following ways.

If *loop = all*, then each processor loops over all atoms in the simulation to create velocities, but only stores velocities for atoms it owns. This can be a slow loop for a large simulation. If atoms were read from a data file, the velocity assigned to a particular atom will be the same, independent of how many processors are being used. This will not be the case if atoms were created using the *create_atoms* command, since atom IDs will likely be assigned to atoms differently.

If *loop = local*, then each processor loops over only its atoms to produce velocities. The random number seed is adjusted to give a different set of velocities on each processor. This is a fast loop, but the velocity assigned to a particular atom will depend on which processor owns it. Thus the results will always be different when a simulation is run on a different number of processors.

If *loop = geom*, then each processor loops over only its atoms. For each atom a unique random number seed is created, based on the atom’s *xyz* coordinates. A velocity is generated using that seed. This is a fast loop and the velocity assigned to a particular atom will be the same, independent of how many processors are used. However, the set of generated velocities may be more correlated than if the *all* or *local* keywords are used.

Note that the *loop geom* keyword will not necessarily assign identical velocities for two simulations run on different machines. This is because the computations based on *xyz* coordinates are sensitive to tiny differences in the double-precision value for a coordinate as stored on a particular machine.

The *rigid* keyword only has meaning when used with the *zero* style. It allows specification of a *fix-ID* for one of the *rigid-body fix* variants which defines a set of rigid bodies. The zeroing of linear or angular momentum is then performed for each rigid body defined by the *fix*, as described above.

The *units* keyword is used by *set* and *ramp*. If *units = box*, the velocities and coordinates specified in the velocity command are in the standard units described by the *units* command (e.g. Angstroms/fs for real units). If *units = lattice*,...
velocities are in units of lattice spacings per time (e.g. spacings/fs) and coordinates are in lattice spacings. The lattice command must have been previously used to define the lattice spacing.

16.136.4 Restrictions

Assigning a temperature via the create style to a system with rigid bodies or SHAKE constraints may not have the desired outcome for two reasons. First, the velocity command can be invoked before all of the relevant fixes are created and initialized and the number of adjusted degrees of freedom (DOFs) is known. Thus it is not possible to compute the target temperature correctly. Second, the assigned velocities may be partially canceled when constraints are first enforced, leading to a different temperature than desired. A workaround for this is to perform a run 0 command, which insures all DOFs are accounted for properly, and then rescale the temperature to the desired value before performing a simulation. For example:

```bash
velocity all create 300.0 12345
run 0
velocity all scale 300.0
```

# temperature may not be 300K
# now it should be

16.136.5 Related commands

fix rigid, fix shake, lattice

16.136.6 Default

The keyword defaults are dist = uniform, sum = no, mom = yes, rot = no, bias = no, loop = all, and units = lattice. The temp and rigid keywords are not defined by default.

16.137 write_coeff command

16.137.1 Syntax

```bash
write_coeff file
```

- file = name of data file to write out

16.137.2 Examples

```bash
write_coeff polymer.coeff
```
16.137.3 Description

Write a text format file with the currently defined force field coefficients in a way, that it can be read by LAMMPS with the `include` command. In combination with the nocoeff option of `write_data` this can be used to move the Coeffs sections from a data file into a separate file.

Note: The write_coeff command is not yet fully implemented as some pair styles do not output their coefficient information. This means you will need to add/copy this information manually.

16.137.4 Restrictions

none

16.138.1 Syntax

```
write_data file keyword value ...
```

- file = name of data file to write out
- zero or more keyword/value pairs may be appended
- keyword = `pair` or `nocoeff`
  - `nocoeff` = do not write out force field info
  - `nofix` = do not write out extra sections read by fixes
  - `pair value` = `ii` or `ij`
    - `ii` = write one line of pair coefficient info per atom type
    - `ij` = write one line of pair coefficient info per IJ atom type pair

16.138.2 Examples

```
write_data data.polymer
write_data data.*
```
16.138.3 Description

Write a data file in text format of the current state of the simulation. Data files can be read by the read data command to begin a simulation. The read_data command also describes their format.

Similar to dump files, the data filename can contain a “*” wild-card character. The “*” is replaced with the current timestep value.

Data in Coeff sections

The write_data command may not always write all coefficient settings to the corresponding Coeff sections of the data file. This can have one of multiple reasons. 1) A few styles may be missing the code that would write those sections (if you come across one, please notify the LAMMPS developers). 2) Some pair styles require a single pair_coeff statement and those are not compatible with data files. 3) The default for write_data is to write a PairCoeff section, which has only entries for atom types i == j. The remaining coefficients would be inferred through the currently selected mixing rule.

If there has been a pair_coeff command with i != j, this setting would be lost. LAMMPS will detect this and print a warning message unless pairij is appended to the write_data command. This will request writing a PairIJCoeff section which has information for all pairs of atom types. In cases where the coefficient data in the data file is incomplete, you will need to re-specify that information in your input script that reads the data file.

Because a data file is in text format, if you use a data file written out by this command to restart a simulation, the initial state of the new run will be slightly different than the final state of the old run (when the file was written) which was represented internally by LAMMPS in binary format. A new simulation which reads the data file will thus typically diverge from a simulation that continued in the original input script.

If you want to do more exact restarts, using binary files, see the restart, write_restart, and read_restart commands. You can also convert binary restart files to text data files, after a simulation has run, using the -r command-line switch.

Note: Only limited information about a simulation is stored in a data file. For example, no information about atom groups and fixes are stored. Binary restart files store more information.

Bond interactions (angle, etc) that have been turned off by the fix shake or delete_bonds command will be written to a data file as if they are turned on. This means they will need to be turned off again in a new run after the data file is read.

Bonds that are broken (e.g. by a bond-breaking potential) are not written to the data file. Thus these bonds will not exist when the data file is read.

The nocoeff keyword requests that no force field parameters should be written to the data file. This can be very helpful, if one wants to make significant changes to the force field or if the parameters are read in separately anyway, e.g. from an include file.

The nofix keyword requests that no extra sections read by fixes should be written to the data file (see the fix option of the read_data command for details). For example, this option excludes sections for user-created per-atom properties from fix property/atom.

The pair keyword lets you specify in what format the pair coefficient information is written into the data file. If the value is specified as ii, then one line per atom type is written, to specify the coefficients for each of the I=J interactions. This means that no cross-interactions for I != J will be specified in the data file and the pair style will apply its mixing rule, as documented on individual pair_style doc pages. Of course this behavior can be overridden in the input script after reading the data file, by specifying additional pair_coeff commands for any desired IJ pairs.

If the value is specified as ij, then one line of coefficients is written for all IJ pairs where I <= J. These coefficients will include any specific settings made in the input script up to that point. The presence of these I != J coefficients in the data file will effectively turn off the default mixing rule for the pair style. Again, the coefficient values in the data file
can be overridden in the input script after reading the data file, by specifying additional `pair_coeff` commands for any desired I,J pairs.

16.138.4 Restrictions

This command requires inter-processor communication to migrate atoms before the data file is written. This means that your system must be ready to perform a simulation before using this command (force fields setup, atom masses initialized, etc).

16.138.5 Related commands

`read_data`, `write_restart`

16.138.6 Default

The option defaults are `pair = ii`.

16.139 write_dump command

16.139.1 Syntax

```
write_dump group-ID style file dump-args modify dump_modify-args
```

- `group-ID` = ID of the group of atoms to be dumped
- `style` = any of the supported dump styles
- `file` = name of file to write dump info to
- `dump-args` = any additional args needed for a particular dump style
- `modify` = all args after this keyword are passed to `dump_modify` (optional)
- `dump-args` = args for `dump_modify` (optional)

16.139.2 Examples

```
write_dump all atom dump.atom

write_dump all image snap*.jpg element element &
    bond atom 0.3 shiny 0.1 ssao yes 6345 0.2 size 1600 1600 &
    modify backcolor white element C C O H N C C O H H S O H
write_dump all atom/gz dump.atom.gz modify compression_level 9
write_dump flow custom/zstd dump.%.myforce.zst &
```

(continues on next page)
16.139.3 Description

Dump a single snapshot of atom quantities to one or more files for the current state of the system. This is a one-time immediate operation, in contrast to the \texttt{dump} command which will set up a dump style to write out snapshots periodically during a running simulation.

The syntax for this command is mostly identical to that of the \texttt{dump} and \texttt{dump_modify} commands as if they were concatenated together, with the following exceptions: There is no need for a dump ID or dump frequency and the keyword \texttt{modify} is added. The latter is so that the full range of \texttt{dump_modify} options can be specified for the single snapshot, just as they can be for multiple snapshots. The \texttt{modify} keyword separates the arguments that would normally be passed to the \texttt{dump} command from those that would be given the \texttt{dump_modify}. Both support optional arguments and thus LAMMPS needs to be able to cleanly separate the two sets of args.

Note that if the specified filename uses wildcard characters “*” or “%”, as supported by the \texttt{dump} command, they will operate in the same fashion to create the new filename(s). Normally, \texttt{dump image} files require a filename with a “*” character for the timestep. That is not the case for the \texttt{write_dump} command; no wildcard “*” character is necessary.

16.139.4 Restrictions

All restrictions for the \texttt{dump} and \texttt{dump_modify} commands apply to this command as well, with the exception of the \texttt{dump image} filename not requiring a wildcard “*” character, as noted above.

Since dumps are normally written during a \texttt{run} or \texttt{energy minimization}, the simulation has to be ready to run before this command can be used. Similarly, if the dump requires information from a compute, fix, or variable, the information needs to have been calculated for the current timestep (e.g. by a prior run), else LAMMPS will generate an error message.

For example, it is not possible to dump per-atom energy with this command before a run has been performed, since no energies and forces have yet been calculated. See the \texttt{variable} doc page section on Variable Accuracy for more information on this topic.

16.139.5 Related commands

\texttt{dump, dump image, dump_modify}

16.139.6 Default

The defaults are listed on the doc pages for the \texttt{dump} and \texttt{dump image} and \texttt{dump_modify} commands.
16.140 write_restart command

16.140.1 Syntax

```
write_restart file keyword value ...
```

- `file` = name of file to write restart information to
- zero or more keyword/value pairs may be appended
- `keyword` = `fileper` or `nfile`
  - `fileper` arg = $N_p$
    - $N_p$ = write one file for every this many processors
  - `nfile` arg = $N_f$
    - $N_f$ = write this many files, one from each of $N_f$ processors

16.140.2 Examples

```
write_restart restart.equil
write_restart restart.equil.mpiio
write_restart poly.%.* nfile 10
```

16.140.3 Description

Write a binary restart file of the current state of the simulation.

During a long simulation, the `restart` command is typically used to output restart files periodically. The `write_restart` command is useful after a minimization or whenever you wish to write out a single current restart file.

Similar to `dump` files, the restart filename can contain two wild-card characters. If a “*” appears in the filename, it is replaced with the current timestep value. If a “%” character appears in the filename, then one file is written by each processor and the “%” character is replaced with the processor ID from 0 to P-1. An additional file with the “%” replaced by “base” is also written, which contains global information. For example, the files written for filename `restart.%` would be `restart.base`, `restart.0`, `restart.1`, ..., `restart.P-1`. This creates smaller files and can be a fast mode of output and subsequent input on parallel machines that support parallel I/O. The optional `fileper` and `nfile` keywords discussed below can alter the number of files written.

The restart file can also be written in parallel as one large binary file via the MPI-IO library, which is part of the MPI standard for versions 2.0 and above. Using MPI-IO requires two steps. First, build LAMMPS with its MPIIO package installed, e.g.

**CMake build**

```
cmake . # enables the MPIIO package in the build folder
cmake --build . # recompiles LAMMPS with the package code included
```

**Traditional make**

```
make yes-mpiio # installs the MPIIO package
make mpi # build LAMMPS for your platform
```
Second, use a restart filename which contains “.mpiio”. Note that it does not have to end in “.mpiio”, just contain those characters. Unlike MPI-IO dump files, a particular restart file must be both written and read using MPI-IO.

Restart files can be read by a read_restart command to restart a simulation from a particular state. Because the file is binary (to enable exact restarts), it may not be readable on another machine. In this case, you can use the -r command-line switch to convert a restart file to a data file.

**Note:** Although the purpose of restart files is to enable restarting a simulation from where it left off, not all information about a simulation is stored in the file. For example, the list of fixes that were specified during the initial run is not stored, which means the new input script must specify any fixes you want to use. Even when restart information is stored in the file, as it is for some fixes, commands may need to be re-specified in the new input script, in order to re-use that information. Details are usually given in the documentation of the respective command. Also, see the read_restart command for general information about what is stored in a restart file.

The optional nfile or fileper keyword can be used in conjunction with the “%” wildcard character in the specified restart file name. As explained above, the “%” character causes the restart file to be written in pieces, one piece for each of P processors. By default P = the number of processors the simulation is running on. The nfile or fileper keyword can be used to set P to a smaller value, which can be more efficient when running on a large number of processors.

The nfile keyword sets P to the specified Nf value. For example, if Nf = 4, and the simulation is running on 100 processors, 4 files will be written, by processors 0,25,50,75. Each will collect information from itself and the next 24 processors and write it to a restart file.

For the fileper keyword, the specified value of Np means write one file for every Np processors. For example, if Np = 4, every fourth processor (0,4,8,12,etc) will collect information from itself and the next 3 processors and write it to a restart file.

16.140.4 Restrictions

This command requires inter-processor communication to migrate atoms before the restart file is written. This means that your system must be ready to perform a simulation before using this command (force fields setup, atom masses initialized, etc).

To write and read restart files in parallel with MPI-IO, the MPIIO package must be installed.

16.140.5 Related commands

restart, read_restart, write_data

16.140.6 Default

none
17.1 fix accelerate/cos command

17.1.1 Syntax

```plaintext
fix ID group-ID accelerate value
```

- ID, group-ID are documented in `fix` command
- accelerate/cos = style name of this fix command
- value = amplitude of acceleration (in unit of velocity/time)

17.1.2 Examples

```plaintext
fix 1 all accelerate/cos 0.02e-5
```

17.1.3 Description

Give each atom a acceleration in x-direction based on its z coordinate. The acceleration is a periodic function along the z-direction:

\[
a_x(z) = A \cos \left( \frac{2\pi z}{l_z} \right)
\]

where \( A \) is the acceleration amplitude, \( l_z \) is the z-length of the simulation box. At steady state, the acceleration generates a velocity profile:

\[
v_x(z) = V \cos \left( \frac{2\pi z}{l_z} \right)
\]

The generated velocity amplitude \( V \) is related to the shear viscosity \( \eta \) by:

\[
V = \frac{A \rho}{\eta} \left( \frac{l_z}{2\pi} \right)^2
\]

and it can be obtained from ensemble average of the velocity profile:

\[
V = \frac{\sum_i 2m_i v_{i,x} \cos \left( \frac{2\pi z_i}{l_z} \right)}{\sum_i m_i}
\]
where $m_i$, $v_{i,x}$ and $z_i$ are the mass, x-component velocity and z coordinate of a particle. The velocity amplitude $V$ can be calculated with *compute viscosity/cos*, which enables viscosity calculation with periodic perturbation method, as described by Hess. Because the applied acceleration drives the system away from equilibration, the calculated shear viscosity is lower than the intrinsic viscosity due to the shear-thinning effect. Extrapolation to zero acceleration should generally be performed to predict the zero-shear viscosity. As the shear stress decreases, the signal-noise ratio decreases rapidly, the simulation time must be extended accordingly to get converged result.

In order to get meaningful result, the group ID of this fix should be all.

### 17.1.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

### 17.1.5 Restrictions

This command is only available when LAMMPS was built with the MISC package. Since this fix depends on the z-coordinate of atoms, it cannot be used in 2d simulations.

### 17.1.6 Related commands

*compute viscosity/cos*

### 17.1.7 Default

`none`

### 17.2 fix acks2/reaxff command

Accelerator Variants: *acks2/reaxff/kk*

#### 17.2.1 Syntax

```
fix ID group-ID acks2/reaxff Nevery cutlo cuthi tolerance params args
```

- ID, group-ID are documented in *fix* command
- acks2/reaxff = style name of this fix command
- Nevery = perform ACKS2 every this many steps
- cutlo,cuthi = lo and hi cutoff for Taper radius
• tolerance = precision to which charges will be equilibrated
• params = reaxff or a filename
• one or more keywords or keyword/value pairs may be appended

keyword = maxiter
maxiter N = limit the number of iterations to N

17.2.2 Examples

```
fix 1 all acks2/reaxff 1 0.0 10.0 1.0e-6 reaxff
fix 1 all acks2/reaxff 1 0.0 10.0 1.0e-6 param.acks2 maxiter 500
```

17.2.3 Description

Perform the atom-condensed Kohn-Sham DFT to second order (ACKS2) charge equilibration method as described in (Verstraelen). ACKS2 impedes unphysical long-range charge transfer sometimes seen with QEq (e.g. for dissociation of molecules), at increased computational cost. It is typically used in conjunction with the ReaxFF force field model as implemented in the `pair_style reaxff` command, but it can be used with any potential in LAMMPS, so long as it defines and uses charges on each atom. For more technical details about the charge equilibration performed by fix acks2/reaxff, see the (O’Hearn) paper.

The ACKS2 method minimizes the electrostatic energy of the system by adjusting the partial charge on individual atoms based on interactions with their neighbors. It requires some parameters for each atom type. If the `params` setting above is the word “reaxff”, then these are extracted from the `pair_style reaxff` command and the ReaxFF force field file it reads in. If a file name is specified for `params`, then the parameters are taken from the specified file and the file must contain one line for each atom type. The latter form must be used when performing QeQ with a non-ReaxFF potential. The lines should be formatted as follows:

```
bond_softness
itype chi eta gamma bcut
```

where the first line is the global parameter `bond_softness`. The remaining 1 to Ntypes lines include `itype`, the atom type from 1 to Ntypes, `chi`, the electronegativity in eV, `eta`, the self-Coulomb potential in eV, `gamma`, the valence orbital exponent, and `bcut`, the bond cutoff distance. Note that these 4 quantities are also in the ReaxFF potential file, except that `eta` is defined here as twice the `eta` value in the ReaxFF file. Note that unlike the rest of LAMMPS, the units of this fix are hard-coded to be Å, eV, and electronic charge.

The optional `maxiter` keyword allows changing the max number of iterations in the linear solver. The default value is 200.

**Note:** In order to solve the self-consistent equations for electronegativity equalization, LAMMPS imposes the additional constraint that all the charges in the fix group must add up to zero. The initial charge assignments should also satisfy this constraint. LAMMPS will print a warning if that is not the case.
17.2.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. This fix computes a global scalar (the number of iterations) for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command.

This fix is invoked during energy minimization.

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

17.2.5 Restrictions

This fix is part of the REAXFF package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This fix does not correctly handle interactions involving multiple periodic images of the same atom. Hence, it should not be used for periodic cell dimensions less than 10 angstroms.

This fix may be used in combination with fix efield and will apply the external electric field during charge equilibration, but there may be only one fix efield instance used, it may only use a constant electric field, and the electric field vector may only have components in non-periodic directions.

17.2.6 Related commands

\texttt{pair_style reaxff}, \texttt{fix qeq/reaxff}

17.2.7 Default

maxiter 200

17.3 fix adapt command

17.3.1 Syntax

```bash
fix ID group-ID adapt N attribute args ... keyword value ...
```

- ID, group-ID are documented in `fix` command
- adapt = style name of this fix command
- N = adapt simulation settings every this many timesteps
- one or more attribute/arg pairs may be appended
- attribute = `pair` or `bond` or `angle` or `kspace` or `atom`
  ```
pair args = pstyle pparam I J v_name
  pstyle = pair style name, e.g. lj/cut
  pparam = parameter to adapt over time
  I, J = type pair(s) to set parameter for
  v_name = variable with name that calculates value of pparam

  bond args = bstyle bparam I v_name
  bstyle = bond style name, e.g. harmonic
  bparam = parameter to adapt over time
  I = type bond to set parameter for
  v_name = variable with name that calculates value of bparam

  angle args = astyle aparam I v_name
  astyle = angle style name, e.g. harmonic
  aparam = parameter to adapt over time
  I = type angle to set parameter for
  v_name = variable with name that calculates value of aparam

  kspace arg = v_name
  v_name = variable with name that calculates scale factor on K-space terms

  atom args = atomparam v_name
  atomparam = parameter to adapt over time
  v_name = variable with name that calculates value of atomparam
  ```
- zero or more keyword/value pairs may be appended
- keyword = `scale` or `reset` or `mass`
  ```
scale value = no or yes
  no = the variable value is the new setting
  yes = the variable value multiplies the original setting

  reset value = no or yes
  no = values will remain altered at the end of a run
  yes = reset altered values to their original values at the end of a run

  mass value = no or yes
  no = mass is not altered by changes in diameter
  yes = mass is altered by changes in diameter
  ```
17.3.2 Examples

```plaintext
fix 1 all adapt 1 pair soft a 1 v_prefactor
fix 1 all adapt 1 pair soft a 2 v_prefactor
fix 1 all adapt 1 pair lj/cut epsilon * * v_scale1 pair coul/cut scale 3 3 v_scale2
   scale yes reset yes
fix 1 all adapt 10 atom diameter v_size
variable ramp_up equal "ramp(0.01,0.5)"
fix stretch all adapt 1 bond harmonic r0 1 v_ramp_up
```

17.3.3 Description

Change or adapt one or more specific simulation attributes or settings over time as a simulation runs. Pair potential and K-space and atom attributes which can be varied by this fix are discussed below. Many other fixes can also be used to time-variation simulation parameters, e.g. the “fix deform” command will change the simulation box size/shape and the “fix move” command will change atom positions and velocities in a prescribed manner. Also note that many commands allow variables as arguments for specific parameters, if described in that manner on their doc pages. An equal-style variable can calculate a time-dependent quantity, so this is another way to vary a simulation parameter over time.

If \( N \) is specified as 0, the specified attributes are only changed once, before the simulation begins. This is all that is needed if the associated variables are not time-dependent. If \( N > 0 \), then changes are made every \( N \) steps during the simulation, presumably with a variable that is time-dependent.

Depending on the value of the `reset` keyword, attributes changed by this fix will or will not be reset back to their original values at the end of a simulation. Even if `reset` is specified as `yes`, a restart file written during a simulation will contain the modified settings.

If the `scale` keyword is set to `no`, which is the default, then the value of the altered parameter will be whatever the variable generates. If the `scale` keyword is set to `yes`, then the value of the altered parameter will be the initial value of that parameter multiplied by whatever the variable generates. i.e. the variable is now a “scale factor” applied in (presumably) a time-varying fashion to the parameter.

Note that whether scale is `no` or `yes`, internally, the parameters themselves are actually altered by this fix. Make sure you use the `reset yes` option if you want the parameters to be restored to their initial values after the run.

The `pair` keyword enables various parameters of potentials defined by the `pair_style` command to be changed, if the pair style supports it. Note that the `pair_style` and `pair_coeff` commands must be used in the usual manner to specify these parameters initially; the fix adapt command simply overrides the parameters.

The `pstyle` argument is the name of the pair style. If `pair_style hybrid or hybrid/overlay` is used, `pstyle` should be a sub-style name. If there are multiple sub-styles using the same pair style, then `pstyle` should be specified as “style:N” where N is which instance of the pair style you wish to adapt, e.g. the first, second, etc. For example, `pstyle` could be specified as “soft” or “lubricate” or “lj/cut:1” or “lj/cut:2”. The `pparam` argument is the name of the parameter to change. This is the current list of pair styles and parameters that can be varied by this fix. See the doc pages for individual pair styles and their energy formulas for the meaning of these parameters:

</table>

Note: It is easy to add new pairwise potentials and their parameters to this list. All it typically takes is adding an extract() method to the pair_*.cpp file associated with the potential.

Some parameters are global settings for the pair style, e.g. the viscosity setting “mu” for pair_style lubricate. Other parameters apply to atom type pairs within the pair style, e.g. the prefactor “a” for pair_style soft.

Note that for many of the potentials, the parameter that can be varied is effectively a prefactor on the entire energy expression for the potential, e.g. the lj/cut epsilon. The parameters listed as “scale” are exactly that, since the energy expression for the coul/cut potential (for example) has no labeled prefactor in its formula. To apply an effective prefactor to some potentials, multiple parameters need to be altered. For example, the Buckingham potential needs both the A and C terms altered together. To scale the Buckingham potential, you should thus list the pair style twice, once for A and once for C.

If a type pair parameter is specified, the I and J settings should be specified to indicate which type pairs to apply it to.

17.3. fix adapt command 1057
If a global parameter is specified, the \( I \) and \( J \) settings still need to be specified, but are ignored.

Similar to the \textit{pair\_coeff} command, \( I \) and \( J \) can be specified in one of two ways. Explicit numeric values can be used for each, as in the first example above. \( I \leq J \) is required. LAMMPS sets the coefficients for the symmetric \( J,I \) interaction to the same values.

A wild-card asterisk can be used in place of or in conjunction with the \( I,J \) arguments to set the coefficients for multiple pairs of atom types. This takes the form “*” or “*n” or “n*” or “m*n”. If \( N \) = the number of atom types, then an asterisk with no numeric values means all types from 1 to \( N \). A leading asterisk means all types from 1 to \( n \) (inclusive). A trailing asterisk means all types from \( n \) to \( N \) (inclusive). A middle asterisk means all types from \( m \) to \( n \) (inclusive). Note that only type pairs with \( I \leq J \) are considered; if asterisks imply type pairs where \( J < I \), they are ignored.

\textbf{IMPORTANT NOTE:} If \textit{pair\_style hybrid} or \textit{hybrid/overlay} is being used, then the \textit{pstyle} will be a sub-style name. You must specify \( I,J \) arguments that correspond to type pair values defined (via the \textit{pair\_coeff} command) for that sub-style.

The \texttt{v\_name} argument for keyword \textit{pair} is the name of an \textit{equal-style variable} which will be evaluated each time this fix is invoked to set the parameter to a new value. It should be specified as \texttt{v\_name}, where \texttt{name} is the variable name. Equal-style variables can specify formulas with various mathematical functions, and include \textit{thermo\_style} command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify parameters that change as a function of time or span consecutive runs in a continuous fashion. For the latter, see the \texttt{start} and \texttt{stop} keywords of the \textit{run} command and the \texttt{elaplong} keyword of \textit{thermo\_style custom} for details.

For example, these commands would change the prefactor coefficient of the \textit{pair\_style soft} potential from 10.0 to 30.0 in a linear fashion over the course of a simulation:

\begin{verbatim}
variable prefactor equal ramp(10,30)
fix 1 all adapt 1 pair soft a * * v\_prefactor
\end{verbatim}

The \textit{bond} keyword uses the specified variable to change the value of a bond coefficient over time, very similar to how the \textit{pair} keyword operates. The only difference is that now a bond coefficient for a given bond type is adapted.

A wild-card asterisk can be used in place of or in conjunction with the bond type argument to set the coefficients for multiple bond types. This takes the form “*” or “*n” or “n*” or “m*n”. If \( N \) = the number of bond types, then an asterisk with no numeric values means all types from 1 to \( N \). A leading asterisk means all types from 1 to \( n \) (inclusive). A trailing asterisk means all types from \( n \) to \( N \) (inclusive). A middle asterisk means all types from \( m \) to \( n \) (inclusive).

Currently \textit{bond} does not support \textit{bond\_style hybrid} nor \textit{bond\_style hybrid/overlay} as bond styles. The bond styles that currently work with \texttt{fix\_adapt} are

\begin{verbatim}
  class2 | r0 | type bonds
  fene   | k,r0 | type bonds
  fene/nm| k,r0 | type bonds
  gromos | k,r0 | type bonds
  harmonic| k,r0 | type bonds
  morse  | r0 | type bonds
  nonlinear | epsilon,r0 | type bonds
\end{verbatim}

The \textit{angle} keyword uses the specified variable to change the value of an angle coefficient over time, very similar to how the \textit{pair} keyword operates. The only difference is that now an angle coefficient for a given angle type is adapted.

A wild-card asterisk can be used in place of or in conjunction with the angle type argument to set the coefficients for multiple angle types. This takes the form “*” or “*n” or “n*” or “m*n”. If \( N \) = the number of angle types, then an asterisk with no numeric values means all types from 1 to \( N \). A leading asterisk means all types from 1 to \( n \) (inclusive). A trailing asterisk means all types from \( n \) to \( N \) (inclusive). A middle asterisk means all types from \( m \) to \( n \) (inclusive).
Currently angle does not support angle_style hybrid nor angle_style hybrid/overlay as angle styles. The angle styles that currently work with fix_adapt are

<table>
<thead>
<tr>
<th>harmonic</th>
<th>( k, \theta_0 )</th>
<th>type angles</th>
</tr>
</thead>
<tbody>
<tr>
<td>cosine</td>
<td>( k )</td>
<td>type angles</td>
</tr>
</tbody>
</table>

Note that internally, \( \theta_0 \) is stored in radians, so the variable this fix uses to reset \( \theta_0 \) needs to generate values in radians.

The kspace keyword uses the specified variable as a scale factor on the energy, forces, virial calculated by whatever K-Space solver is defined by the kspace_style command. If the variable has a value of 1.0, then the solver is unaltered.

The kspace keyword works this way whether the scale keyword is set to no or yes.

The atom keyword enables various atom properties to be changed. The aparam argument is the name of the parameter to change. This is the current list of atom parameters that can be varied by this fix:

- charge = charge on particle
- diameter or diameter/disc = diameter of particle

The v_name argument of the atom keyword is the name of an equal-style variable which will be evaluated each time this fix is invoked to set, or scale the parameter to a new value. It should be specified as v_name, where name is the variable name. See the discussion above describing the formulas associated with equal-style variables. The new value is assigned to the corresponding attribute for all atoms in the fix group.

If the atom parameter is diameter and per-atom density and per-atom mass are defined for particles (e.g. atom_style granular), then the mass of each particle is, by default, also changed when the diameter changes. The mass is set from the particle volume for 3d systems (density is assumed to stay constant). For 2d, the default is for LAMMPS to model particles with a radius attribute as spheres. However, if the atom parameter is diameter/disc, then the mass is set from the particle area (the density is assumed to be in mass/distance^2 units). The mass of the particle may also be kept constant if the mass keyword is set to no. This can be useful to account for diameter changes that do not involve mass changes, e.g., thermal expansion.

For example, these commands would shrink the diameter of all granular particles in the “center” group from 1.0 to 0.1 in a linear fashion over the course of a 1000-step simulation:

```bash
variable size equal ramp(1.0,0.1)
fix 1 center adapt 10 atom diameter v_size
```

This fix can be used in long simulations which are restarted one or more times to continuously adapt simulation parameters, but it must be done carefully. There are two issues to consider. The first is how to adapt the parameters in a continuous manner from one simulation to the next. The second is how, if desired, to reset the parameters to their original values at the end of the last restarted run.

Note that all the parameters changed by this fix are written into a restart file in their current changed state. A new restarted simulation does not know their original time=0 values, unless the input script explicitly resets the parameters (after the restart file is read), to their original values.

Also note, that the time-dependent variable(s) used in the restart script should typically be written as a function of time elapsed since the original simulation began.

With this in mind, if the scale keyword is set to no (the default) in a restarted simulation, original parameters are not needed. The adapted parameters should seamlessly continue their variation relative to the preceding simulation.
If the `scale` keyword is set to `yes`, then the input script should typically reset the parameters being adapted to their original values, so that the scaling formula specified by the variable will operate correctly. An exception is if the `atom` keyword is being used with `scale yes`. In this case, information is added to the restart file so that per-atom properties in the new run will automatically be scaled relative to their original values. This will only work if the fix adapt command specified in the restart script has the same ID as the one used in the original script.

In a restarted run, if the `reset` keyword is set to `yes`, and the run ends in this script (as opposed to just writing more restart files, parameters will be restored to the values they were at the beginning of the run command in the restart script. Which as explained above, may or may not be the original values of the parameters. Again, an exception is if the `atom` keyword is being used with `reset yes` (in all the runs). In that case, the original per-atom parameters are stored in the restart file, and will be restored when the restarted run finally completes.

17.3.4 Restart, fix modify, output, run start/stop, minimize info

If the `atom` keyword is used and the `scale` or `reset` keyword is set to `yes`, then this fix writes information to a restart file so that in a restarted run scaling can continue in a seamless manner and/or the per-atom values can be restored, as explained above.

None of the `fix modify` options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various `output commands`. No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during energy minimization.

For `rRESPA time integration`, this fix changes parameters on the outermost rRESPA level.

17.3.5 Restrictions

`none`

17.3.6 Related commands

`compute ti`

17.3.7 Default

The option defaults are `scale = no`, `reset = no`, `mass = yes`.

17.4 fix adapt/fep command

17.4.1 Syntax

```
fix ID group-ID adapt/fep N attribute args ... keyword value ...
```

- ID, group-ID are documented in `fix` command
- `adapt/fep` = style name of this `fix` command
- `N` = adapt simulation settings every this many timesteps
- one or more attribute/arg pairs may be appended

Example input scripts available: examples/PACKAGES/fep

17.4.3 Description

Change or adapt one or more specific simulation attributes or settings over time as a simulation runs.

This is an enhanced version of the `fix adapt` command with two differences,

- It is possible to modify the charges of chosen atom types only, instead of scaling all the charges in the system.
- There is a new option `after` for better compatibility with “fix ave/time”.

This version is suited for free energy calculations using `compute ti` or `compute fep`.

If \( N \) is specified as 0, the specified attributes are only changed once, before the simulation begins. This is all that is needed if the associated variables are not time-dependent. If \( N > 0 \), then changes are made every \( N \) steps during the simulation, presumably with a variable that is time-dependent.
Depending on the value of the `reset` keyword, attributes changed by this fix will or will not be reset back to their original values at the end of a simulation. Even if `reset` is specified as `yes`, a restart file written during a simulation will contain the modified settings.

If the `scale` keyword is set to `no`, then the value the parameter is set to will be whatever the variable generates. If the `scale` keyword is set to `yes`, then the value of the altered parameter will be the initial value of that parameter multiplied by whatever the variable generates. I.e. the variable is now a “scale factor” applied in (presumably) a time-varying fashion to the parameter. Internally, the parameters themselves are actually altered; make sure you use the `reset yes` option if you want the parameters to be restored to their initial values after the run.

If the `after` keyword is set to `yes`, then the parameters are changed one timestep after the multiple of N. In this manner, if a fix such as “fix ave/time” is used to calculate averages at every N timesteps, all the contributions to the average will be obtained with the same values of the parameters.

The `pair` keyword enables various parameters of potentials defined by the `pair_style` command to be changed, if the pair style supports it. Note that the `pair_style` and `pair_coeff` commands must be used in the usual manner to specify these parameters initially; the fix `adapt` command simply overrides the parameters.

The `pstyle` argument is the name of the pair style. If `pair_style hybrid` or `hybrid/overlay` is used, `pstyle` should be a sub-style name. For example, `pstyle` could be specified as “soft” or “lubricate”. The `pparam` argument is the name of the parameter to change. This is the current list of pair styles and parameters that can be varied by this fix. See the doc pages for individual pair styles and their energy formulas for the meaning of these parameters:

1062 Chapter 17. Fixes
Note: It is easy to add new potentials and their parameters to this list. All it typically takes is adding an extract() method to the pair_*.cpp file associated with the potential.

Note that for many of the potentials, the parameter that can be varied is effectively a prefactor on the entire energy expression for the potential, e.g. the lj/cut epsilon. The parameters listed as “scale” are exactly that, since the energy expression for the coul/cut potential (for example) has no labeled prefactor in its formula. To apply an effective prefactor to some potentials, multiple parameters need to be altered. For example, the Buckingham potential needs both the A and C terms altered together. To scale the Buckingham potential, you should thus list the pair style twice, once for A and once for C.

If a type pair parameter is specified, the I and J settings should be specified to indicate which type pairs to apply it to. If a global parameter is specified, the I and J settings still need to be specified, but are ignored.

Similar to the pair_coeff command, I and J can be specified in one of two ways. Explicit numeric values can be used for each, as in the first example above. I <= J is required. LAMMPS sets the coefficients for the symmetric J,I interaction to the same values.

A wild-card asterisk can be used in place of or in conjunction with the IJ arguments to set the coefficients for multiple pairs of atom types. This takes the form “*n” or “n*” or “m*n” or “m*n”. If N = the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from m to n (inclusive). Note that only type pairs with I <= J are considered; if asterisks imply type pairs where J < I, they are ignored.

IMPORTANT NOTE: If pair_style hybrid or hybrid/overlay is being used, then the pstyle will be a sub-style name. You must specify I,J arguments that correspond to type pair values defined (via the pair_coeff command) for that sub-style.

The v_name argument for keyword pair is the name of an equal-style variable which will be evaluated each time this fix is invoked to set the parameter to a new value. It should be specified as v_name, where name is the variable name. Equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify parameters that change as a function of time or span consecutive runs in a continuous fashion. For the latter, see the start and stop keywords of the run command and the elaplong keyword of thermo_style custom for details.

For example, these commands would change the prefactor coefficient of the pair_style soft potential from 10.0 to 30.0 in a linear fashion over the course of a simulation:

```
variable prefactor equal ramp(10,30)
fix 1 all adapt 1 pair soft a * * v_prefactor
```

The kspace keyword used the specified variable as a scale factor on the energy, forces, virial calculated by whatever K-Space solver is defined by the kspace_style command. If the variable has a value of 1.0, then the solver is unaltered.

The kspace keyword works this way whether the scale keyword is set to no or yes.

The atom keyword enables various atom properties to be changed. The aparam argument is the name of the parameter to change. This is the current list of atom parameters that can be varied by this fix:

- charge = charge on particle
- diameter = diameter of particle

The I argument indicates which atom types are affected. A wild-card asterisk can be used in place of or in conjunction with the I argument to set the coefficients for multiple atom types.

The v_name argument of the atom keyword is the name of an equal-style variable which will be evaluated each time this fix is invoked to set the parameter to a new value. It should be specified as v_name, where name is the variable name.
See the discussion above describing the formulas associated with equal-style variables. The new value is assigned to the corresponding attribute for all atoms in the fix group.

If the atom parameter is `diameter` and per-atom density and per-atom mass are defined for particles (e.g. `atom_style granular`), then the mass of each particle is also changed when the diameter changes (density is assumed to stay constant).

For example, these commands would shrink the diameter of all granular particles in the “center” group from 1.0 to 0.1 in a linear fashion over the course of a 1000-step simulation:

```plaintext
variable size equal ramp(1.0,0.1)
fix 1 center adapt 10 atom diameter * v_size
```

For rRESPA time integration, this fix changes parameters on the outermost rRESPA level.

### 17.4.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

### 17.4.5 Restrictions

none

### 17.4.6 Related commands

`compute fep, fix adapt, compute ti, pair_style */soft`

### 17.4.7 Default

The option defaults are scale = no, reset = no, after = no.

### 17.5 fix addforce command

#### 17.5.1 Syntax

```plaintext
fix ID group-ID addforce fx fy fz keyword value ...
```

- ID, group-ID are documented in fix command
- addforce = style name of this fix command
- fx,fy,fz = force component values (force units)
- any of fx,fy,fz can be a variable (see below)
- zero or more keyword/value pairs may be appended to args
• keyword = *every* or *region* or *energy*

  *every* value = Nevery

  Nevery = add force every this many timesteps

  *region* value = region-ID

  region-ID = ID of region atoms must be in to have added force

  *energy* value = v_name

  v_name = variable with name that calculates the potential energy of each atom in the added force field

17.5.2 Examples

```
fix kick flow addforce 1.0 0.0 0.0
fix kick flow addforce 1.0 0.0 v_oscillate
fix ff boundary addforce 0.0 0.0 v_push energy v_espace
```

17.5.3 Description

Add \( f_x, f_y, f_z \) to the corresponding component of force for each atom in the group. This command can be used to give an additional push to atoms in a simulation, such as for a simulation of Poiseuille flow in a channel.

Any of the 3 quantities defining the force components can be specified as an equal-style or atom-style variable, namely \( f_x, f_y, f_z \). If the value is a variable, it should be specified as \( v\text{\_name} \), where \( \text{name} \) is the variable name. In this case, the variable will be evaluated each timestep, and its value(s) used to determine the force component.

Equal-style variables can specify formulas with various mathematical functions, and include *thermo_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent force field.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus it is easy to specify a spatially-dependent force field with optional time-dependence as well.

If the *every* keyword is used, the *Nevery* setting determines how often the forces are applied. The default value is 1, for every timestep.

If the *region* keyword is used, the atom must also be in the specified geometric region in order to have force added to it.

Adding a force to atoms implies a change in their potential energy as they move due to the applied force field. For dynamics via the “run” command, this energy can be optionally added to the system’s potential energy for thermodynamic output (see below). For energy minimization via the “minimize” command, this energy must be added to the system’s potential energy to formulate a self-consistent minimization problem (see below).

The *energy* keyword is not allowed if the added force is a constant vector \( F = (f_x,f_y,f_z) \), with all components defined as numeric constants and not as variables. This is because LAMMPS can compute the energy for each atom directly as \( E = -x \cdot F = -(x*f_x + y*f_y + z*f_z) \), so that \(-\text{Grad}(E) = F\).

The *energy* keyword is optional if the added force is defined with one or more variables, and if you are performing dynamics via the *run* command. If the keyword is not used, LAMMPS will set the energy to \(0.0\), which is typically fine for dynamics.

The *energy* keyword is required if the added force is defined with one or more variables, and you are performing energy minimization via the “minimize” command. The keyword specifies the name of an atom-style variable which is used to compute the energy of each atom as function of its position. Like variables used for \( f_x, f_y, f_z \), the energy variable is specified as \( v\text{\_name} \), where \( \text{name} \) is the variable name.
Note that when the energy keyword is used during an energy minimization, you must insure that the formula defined for the atom-style variable is consistent with the force variable formulas, i.e. that \(-\nabla E = F\). For example, if the force were a spring-like \(F = kx\), then the energy formula should be \(E = -0.5kx^2\). If you don’t do this correctly, the minimization will not converge properly.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 17.5.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify energy option is supported by this fix to add the potential energy inferred by the added force to the global potential energy of the system as part of thermodynamic output. The default setting for this fix is fix_modify energy no. Note that this energy is a fictitious quantity but is needed so that the minimize command can include the forces added by this fix in a consistent manner. I.e. there is a decrease in potential energy when atoms move in the direction of the added force.

The fix_modify virial option is supported by this fix to add the contribution due to the added forces on atoms to both the global pressure and per-atom stress of the system via the compute pressure and compute stress/atom commands. The former can be accessed by thermodynamic output. The default setting for this fix is fix_modify virial no.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar and a global 3-vector of forces, which can be accessed by various output commands. The scalar is the potential energy discussed above. The vector is the total force on the group of atoms before the forces on individual atoms are changed by the fix. The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command. You should not specify force components with a variable that has time-dependence for use with a minimizer, since the minimizer increments the timestep as the iteration count during the minimization.

**Note:** If you want the fictitious potential energy associated with the added forces to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the fix_modify energy option for this fix.
17.5.5 Restrictions

none

17.5.6 Related commands

fix setforce, fix aveforce

17.5.7 Default

The option default for the every keyword is every = 1.

17.6 fix addtorque command

17.6.1 Syntax

```plaintext
fix ID group-ID addtorque Tx Ty Tz
```

- ID, group-ID are documented in fix command
- addtorque = style name of this fix command
- Tx, Ty, Tz = torque component values (torque units)
- any of Tx, Ty, Tz can be a variable (see below)

17.6.2 Examples

```plaintext
fix kick bead addtorque 2.0 3.0 5.0
fix kick bead addtorque 0.0 0.0 v_oscillate
```

17.6.3 Description

Add a set of forces to each atom in the group such that:

- the components of the total torque applied on the group (around its center of mass) are Tx, Ty, Tz
- the group would move as a rigid body in the absence of other forces.

This command can be used to drive a group of atoms into rotation.

Any of the 3 quantities defining the torque components can be specified as an equal-style variable, namely \( T_x, T_y, T_z \). If the value is a variable, it should be specified as \( v\text{\_name} \), where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the torque component.

Equal-style variables can specify formulas with various mathematical functions, and include \( \text{thermo\_style} \) command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent torque.
17.6.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify energy option is supported by this fix to add the potential “energy” inferred by the added torques to the global potential energy of the system as part of thermodynamic output. The default setting for this fix is fix_modify energy no. Note that this is a fictitious quantity but is needed so that the minimize command can include the forces added by this fix in a consistent manner. I.e. there is a decrease in potential energy when atoms move in the direction of the added forces.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its torque. Default is the outermost level.

This fix computes a global scalar and a global 3-vector, which can be accessed by various output commands. The scalar is the potential energy discussed above. The vector is the total torque on the group of atoms before the forces on individual atoms are changed by the fix. The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command.

**Note:** If you want the fictitious potential energy associated with the added forces to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the fix_modify energy option for this fix.

**Note:** You should not specify force components with a variable that has time-dependence for use with a minimizer, since the minimizer increments the timestep as the iteration count during the minimization.

17.6.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

17.6.6 Related commands

fix addforce

17.6.7 Default

none

17.7 fix append/atoms command

17.7.1 Syntax

```plaintext
fix ID group-ID append/atoms face ... keyword value ...
```

- ID, group-ID are documented in fix command
- append/atoms = style name of this fix command
• face = zhi

• zero or more keyword/value pairs may be appended

• keyword = basis or size or freq or temp or random or units

  | Basis values = M itype
  | M = which basis atom
  | itype = atom type (1-N) to assign to this basis atom

  | Size args = Lz
  | Lz = z size of lattice region appended in a single event (distance units)

  | Freq args = freq
  | freq = the number of timesteps between append events

  | Temp args = target damp seed extent
  | target = target temperature for the region between zhi-extent and zhi
  | damp = damping parameter (time units)
  | seed = random number seed for langevin kicks
  | extent = extent of thermostatted region (distance units)

  | Random args = xmax ymax zmax seed
  | xmax, ymax, zmax = maximum displacement in particular direction (distance units)
  | seed = random number seed for random displacement

  | Units value = lattice or box
  | lattice = the wall position is defined in lattice units
  | box = the wall position is defined in simulation box units

17.7.2 Examples

fix 1 all append/atoms zhi size 5.0 freq 295 units lattice
fix 4 all append/atoms zhi size 15.0 freq 5 units box
fix A all append/atoms zhi size 1.0 freq 1000 units lattice

17.7.3 Description

This fix creates atoms on a lattice, appended on the zhi edge of the system box. This can be useful when a shock or wave is propagating from zlo. This allows the system to grow with time to accommodate an expanding wave. A simulation box must already exist, which is typically created via the create_box command. Before using this command, a lattice must also be defined using the lattice command.

This fix will automatically freeze atoms on the zhi edge of the system, so that overlaps are avoided when new atoms are appended.

The basis keyword specifies an atom type that will be assigned to specific basis atoms as they are created. See the lattice command for specifics on how basis atoms are defined for the unit cell of the lattice. By default, all created atoms are assigned type = 1 unless this keyword specifies differently.

The size keyword defines the size in z of the chunk of material to be added.

The random keyword will give the atoms random displacements around their lattice points to simulate some initial temperature.

The temp keyword will cause a region to be thermostatted with a Langevin thermostat on the zhi boundary. The size of the region is measured from zhi and is set with the extent argument.

The units keyword determines the meaning of the distance units used to define a wall position, but only when a numeric constant is used. A box value selects standard distance units as defined by the units command, e.g. Angstroms for units...
= real or metal. A lattice value means the distance units are in lattice spacings. The lattice command must have been previously used to define the lattice spacings.

17.7.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.7.5 Restrictions

This fix style is part of the SHOCK package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

The boundary on which atoms are added with append/atoms must be shrink/minimum. The opposite boundary may be any boundary type other than periodic.

17.7.6 Related commands

fix wall/piston command

17.7.7 Default

The keyword defaults are size = 0.0, freq = 0, units = lattice. All added atoms are of type 1 unless the basis keyword is used.

17.8 fix atc command

17.8.1 Syntax

fix <fixID> <group> atc <type> <parameter_file>

• fixID = name of fix
• group = name of group fix is to be applied
• type = thermal or two_temperature or hardy or field

thermal = thermal coupling with fields: temperature

two_temperature = electron-phonon coupling with field: temperature and electron_temperature

hardy = on-the-fly post-processing using kernel localization functions

field = on-the-fly post-processing using mesh-based localization functions

• parameter_file = name of the file with material parameters. Note: Neither hardy nor field requires a parameter file
17.8.2 Examples

<table>
<thead>
<tr>
<th>fix</th>
<th>AtC internal</th>
<th>atc thermal Ar_thermal.dat</th>
</tr>
</thead>
<tbody>
<tr>
<td>fix</td>
<td>AtC internal</td>
<td>atc two_temperature Ar_ttm.mat</td>
</tr>
<tr>
<td>fix</td>
<td>AtC internal</td>
<td>atc hardy</td>
</tr>
<tr>
<td>fix</td>
<td>AtC internal</td>
<td>atc field</td>
</tr>
</tbody>
</table>

17.8.3 Description

This fix is the beginning to creating a coupled FE/MD simulation and/or an on-the-fly estimation of continuum fields. The coupled versions of this fix do Verlet integration and the post-processing does not. After instantiating this fix, several other fix_modify commands will be needed to set up the problem, e.g. define the finite element mesh and prescribe initial and boundary conditions.

The following coupling example is typical, but non-exhaustive:

```
# ... commands to create and initialize the MD system

# initial fix to designate coupling type and group to apply it to
# tag group physics material_file
fix AtC internal atc thermal Ar_thermal.mat

# create a uniform 12 x 2 x 2 mesh that covers region contain the group
# nx ny nz region periodicity
fix_modify AtC mesh create 12 2 2 mdRegion f p p

# specify the control method for the type of coupling
# physics control_type
fix_modify AtC thermal control flux

# specify the initial values for the empirical field "temperature"
# field node_group value
fix_modify AtC initial temperature all 30
```

(continues on next page)
likewise for this post-processing example:

```bash
# ... commands to create and initialize the MD system
# initial fix to designate post-processing and the group to apply it to
# no material file is allowed nor required
fix AtC internal atc hardy

# for hardy fix, specific kernel function (function type and range) to # be used as a localization function
fix AtC kernel quartic_sphere 10.0

# create a uniform 1 x 1 x 1 mesh that covers region contain the group
# with periodicity this effectively creates a system average
fix_modify AtC mesh create 1 1 1 box p p p

# change from default lagrangian map to eulerian
# refreshed every 100 steps
fix_modify AtC atom_element_map eulerian 100

# start with no field defined
# add mass density, potential energy density, stress and temperature
fix_modify AtC fields add density energy stress temperature

# create an output stream for nodal fields
# filename output_frequency
fix_modify AtC output nvtFE 100 text

run 1000
```

the mesh’s linear interpolation functions can be used as the localization function by using the field option:

```bash
fix AtC internal atc field
fix_modify AtC mesh create 1 1 1 box p p p
```

Note coupling and post-processing can be combined in the same simulations using separate fixes.
17.8.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify energy option is not supported by this fix, but this fix does add the kinetic energy imparted to atoms by the momentum coupling mode of the AtC package to the global potential energy of the system as part of thermodynamic output.

Additional fix_modify options relevant to this fix are listed below.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the energy discussed in the previous paragraph. The scalar value is “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.8.5 Restrictions

Thermal and two_temperature (coupling) types use a Verlet time-integration algorithm. The hardy type does not contain its own time-integrator and must be used with a separate fix that does contain one, e.g. nve, nvt, etc. In addition, currently:

- the coupling is restricted to thermal physics
- the FE computations are done in serial on each processor.

17.8.6 Related commands

After specifying this fix in your input script, several fix_modify AtC commands are used to setup the problem, e.g. define the finite element mesh and prescribe initial and boundary conditions. Each of these options has its own doc page.

fix_modify commands for setup:

- fix_modify AtC mesh create
- fix_modify AtC mesh quadrature
- fix_modify AtC mesh read
- fix_modify AtC mesh write
- fix_modify AtC mesh create_nodeset
- fix_modify AtC mesh add_to_nodeset
- fix_modify AtC mesh create_faceset box
- fix_modify AtC mesh create_faceset plane
- fix_modify AtC mesh create_elementset
- fix_modify AtC mesh delete_elements
- fix_modify AtC mesh nodeset_to_elementset
- fix_modify AtC boundary type
- fix_modify AtC internal_quadrature
- fix_modify AtC time_integration
- fix_modify AtC extrinsic electron_integration
• `fix_modify AtC internal_element_set`
• `fix_modify AtC decomposition`

**fix_modify commands for boundary and initial conditions:**

• `fix_modify AtC initial`
• `fix_modify AtC fix`
• `fix_modify AtC unfix`
• `fix_modify AtC fix_flux`
• `fix_modify AtC unfix_flux`
• `fix_modify AtC source`
• `fix_modify AtC remove_source`

**fix_modify commands for control and filtering:**

• `fix_modify AtC control thermal`
• `fix_modify AtC control momentum`
• `fix_modify AtC control localized_lambda`
• `fix_modify AtC control lumped_lambda_solve`
• `fix_modify AtC control mask_direction`
• `fix_modify AtC filter`
• `fix_modify AtC filter scale`
• `fix_modify AtC filter type`
• `fix_modify AtC equilibrium_start`
• `fix_modify AtC extrinsic exchange`
• `fix_modify AtC poisson_solver`

**fix_modify commands for output:**

• `fix_modify AtC output`
• `fix_modify AtC output nodeset`
• `fix_modify AtC output volume_integral`
• `fix_modify AtC output boundary_integral`
• `fix_modify AtC output contour_integral`
• `fix_modify AtC mesh output`
• `fix_modify AtC write_restart`
• `fix_modify AtC read_restart`

**fix_modify commands for post-processing:**

• `fix_modify AtC kernel`
• `fix_modify AtC fields`
• `fix_modify AtC gradients`
• `fix_modify AtC rates`
• `fix_modify AtC computes`
• `fix_modify AtC on_the_fly`
• `fix_modify AtC pair/bond_interactions`
• `fix_modify AtC sample_frequency`
• `fix_modify AtC set`

miscellaneous `fix_modify` commands:

• `fix_modify AtC atom_element_map`
• `fix_modify AtC atom_weight`
• `fix_modify AtC write_atom_weights`
• `fix_modify AtC kernel_bandwidth`
• `fix_modify AtC reset_time`
• `fix_modify AtC reset_atomic_reference_positions`
• `fix_modify AtC fe_md_boundary`
• `fix_modify AtC boundary_faceset`
• `fix_modify AtC consistent_fe_initialization`
• `fix_modify AtC mass_matrix`
• `fix_modify AtC material`
• `fix_modify AtC atomic_charge`
• `fix_modify AtC source_integration`
• `fix_modify AtC temperature_definition`
• `fix_modify AtC track_displacement`
• `fix_modify AtC boundary_dynamics`
• `fix_modify AtC add_species`
• `fix_modify AtC add_molecule`
• `fix_modify AtC remove_species`
• `fix_modify AtC remove_molecule`

Note: a set of example input files with the attendant material files are included in the `examples/PACKAGES/atc` folders.

17.8.7 Default

None

For detailed exposition of the theory and algorithms please see:
17.9 fix atom/swap command

17.9.1 Syntax

```
fix ID group-ID atom/swap N X seed T keyword values ...
```

- ID, group-ID are documented in `fix` command
- atom/swap = style name of this fix command
- N = invoke this fix every N steps
- X = number of swaps to attempt every N steps
- seed = random # seed (positive integer)
- T = scaling temperature of the MC swaps (temperature units)
- one or more keyword/value pairs may be appended to args
- keyword = types or mu or ke or semi-grand or region

  types values = two or more atom types
  mu values = chemical potential of swap types (energy units)
  ke value = no or yes
    no = no conservation of kinetic energy after atom swaps
    yes = kinetic energy is conserved after atom swaps
  semi-grand value = no or yes
    no = particle type counts and fractions conserved
    yes = semi-grand canonical ensemble, particle fractions not conserved
  region value = region-ID
  region-ID = ID of region to use as an exchange/move volume
17.9.2 Examples

| fix 2 all atom/swap 1 1 29494 300.0 ke no types 1 2 |
| fix myFix all atom/swap 100 1 12345 298.0 region my_swap_region types 5 6 |
| fix SGMC all atom/swap 1 100 345 1.0 semi-grand yes types 1 2 3 mu 0.0 4.3 -5.0 |

17.9.3 Description

This fix performs Monte Carlo swaps of atoms of one given atom type with atoms of the other given atom types. The specified T is used in the Metropolis criterion dictating swap probabilities.

Perform X swaps of atoms of one type with atoms of another type according to a Monte Carlo probability. Swap candidates must be in the fix group, must be in the region (if specified), and must be of one of the listed types. Swaps are attempted between candidates that are chosen randomly with equal probability among the candidate atoms. Swaps are not attempted between atoms of the same type since nothing would happen.

All atoms in the simulation domain can be moved using regular time integration displacements, e.g. via `fix nvt`, resulting in a hybrid MC+MD simulation. A smaller-than-usual timestep size may be needed when running such a hybrid simulation, especially if the swapped atoms are not well equilibrated.

The `types` keyword is required. At least two atom types must be specified.

The `ke` keyword can be set to `no` to turn off kinetic energy conservation for swaps. The default is `yes`, which means that swapped atoms have their velocities scaled by the ratio of the masses of the swapped atom types. This ensures that the kinetic energy of each atom is the same after the swap as it was before the swap, even though the atom masses have changed.

The `semi-grand` keyword can be set to `yes` to switch to the semi-grand canonical ensemble as discussed in (Sadigh). This means that the total number of each particle type does not need to be conserved. The default is `no`, which means that the only kind of swap allowed exchanges an atom of one type with an atom of a different given type. In other words, the relative mole fractions of the swapped atoms remains constant. Whereas in the semi-grand canonical ensemble, the composition of the system can change. Note that when using `semi-grand`, atoms in the fix group whose type is not listed in the `types` keyword are ineligible for attempted conversion. An attempt is made to switch the selected atom (if eligible) to one of the other listed types with equal probability. Acceptance of each attempt depends upon the Metropolis criterion.

The `mu` keyword allows users to specify chemical potentials. This is required and allowed only when using `semi-grand`. All chemical potentials are absolute, so there is one for each swap type listed following the `types` keyword. In semi-grand canonical ensemble simulations the chemical composition of the system is controlled by the difference in these values. So shifting all values by a constant amount will have no effect on the simulation.

This command may optionally use the `region` keyword to define swap volume. The specified region must have been previously defined with a `region` command. It must be defined with `side = in`. Swap attempts occur only between atoms that are both within the specified region. Swaps are not otherwise attempted.

You should ensure you do not swap atoms belonging to a molecule, or LAMMPS will eventually generate an error when it tries to find those atoms. LAMMPS will warn you if any of the atoms eligible for swapping have a non-zero molecule ID, but does not check for this at the time of swapping.

If not using `semi-grand` this fix checks to ensure all atoms of the given types have the same atomic charge. LAMMPS does not enforce this in general, but it is needed for this fix to simplify the swapping procedure. Successful swaps will swap the atom type and charge of the swapped atoms. Conversely, when using `semi-grand`, it is assumed that all the atom types involved in switches have the same charge. Otherwise, charge would not be conserved. As a consequence, no checks on atomic charges are performed, and successful switches update the atom type but not the atom charge. While it is possible to use `semi-grand` with groups of atoms that have different charges, these charges will not be changed when the atom types change.
Since this fix computes total potential energies before and after proposed swaps, so even complicated potential energy calculations are OK, including the following:

- long-range electrostatics (kspace)
- many body pair styles
- hybrid pair styles
- eam pair styles
- triclinic systems
- need to include potential energy contributions from other fixes

Some fixes have an associated potential energy. Examples of such fixes include: *efield*, *gravity*, *addforce*, *langevin*, *restrain*, *temp/berendsen*, *temp/rescale*, and *wall fixes*. For that energy to be included in the total potential energy of the system (the quantity used when performing GCMC moves), you MUST enable the *fix_modify energy* option for that fix. The doc pages for individual *fix* commands specify if this should be done.

### 17.9.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the fix to *binary restart files*. This includes information about the random number generator seed, the next timestep for MC exchanges, the number of exchange attempts and successes etc. See the *read_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

**Note:** For this to work correctly, the timestep must **not** be changed after reading the restart with *reset_timestep*. The fix will try to detect it and stop with an error.

None of the *fix_modify* options are relevant to this fix.

This fix computes a global vector of length 2, which can be accessed by various *output commands*. The vector values are the following global cumulative quantities:

- 1 = swap attempts
- 2 = swap accepts

The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

### 17.9.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

17.10 fix ave/atom command

17.10.1 Syntax

fix ID group-ID ave/atom Nevery Nrepeat Nfreq value1 value2 ...

• ID, group-ID are documented in fix command
• ave/atom = style name of this fix command
• Nevery = use input values every this many timesteps
• Nrepeat = # of times to use input values for calculating averages
• Nfreq = calculate averages every this many timesteps one or more input values can be listed
• value = x, y, z, vx, vy, vz, fx, fy, fz, c_ID, c_ID[i], f_ID, f_ID[i], v_name

x,y,z,vx,vy,vz,fx, fy, fz = atom attribute (position, velocity, force component)
c_ID = per-atom vector calculated by a compute with ID
c_ID[i] = Ith column of per-atom array calculated by a compute with ID, I can include wildcard (see below)
f_ID = per-atom vector calculated by a fix with ID
f_ID[i] = Ith column of per-atom array calculated by a fix with ID, I can include wildcard (see below)
v_name = per-atom vector calculated by an atom-style variable with name

17.10.2 Examples

fix 1 all ave/atom 1 100 100 vx vy vz
fix 1 all ave/atom 10 20 1000 c_my_stress[1]
fix 1 all ave/atom 10 20 1000 c_my_stress[*]
17.10.3 Description

Use one or more per-atom vectors as inputs every few timesteps, and average them atom by atom over longer timescales. The resulting per-atom averages can be used by other output commands such as the fix ave/chunk or dump custom commands.

The group specified with the command means only atoms within the group have their averages computed. Results are set to 0.0 for atoms not in the group.

Each input value can be an atom attribute (position, velocity, force component) or can be the result of a compute or fix or the evaluation of an atom-style variable. In the latter cases, the compute, fix, or variable must produce a per-atom vector, not a global quantity or local quantity. If you wish to time-average global quantities from a compute, fix, or variable, then see the fix ave/time command.

Each per-atom value of each input vector is averaged independently. Computes that produce per-atom vectors or arrays are those which have the word atom in their style name. See the doc pages for individual fixes to determine which ones produce per-atom vectors or arrays. Variables of style atom are the only ones that can be used with this fix since they produce per-atom vectors.

Note that for values from a compute or fix, the bracketed index I can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form "*" or "n*" or "n/*" or "m*n". If N = the size of the vector (for mode = scalar) or the number of columns in the array (for mode = vector), then an asterisk with no numeric values means all indices from 1 to N. A leading asterisk means all indices from 1 to n (inclusive). A trailing asterisk means all indices from n to N (inclusive). A middle asterisk means all indices from m to n (inclusive).

Using a wildcard is the same as if the individual columns of the array had been listed one by one. E.g. these 2 fix ave/atom commands are equivalent, since the compute stress/atom command creates a per-atom array with 6 columns:

```
compute my_stress all stress/atom NULL
fix 1 all ave/atom 10 20 1000 c_my_stress[*]
```

The Nevery, Nrepeat, and Nfreq arguments specify on what timesteps the input values will be used in order to contribute to the average. The final averaged quantities are generated on timesteps that are a multiple of Nfreq. The average is over Nrepeat quantities, computed in the preceding portion of the simulation every Nevery timesteps. Nfreq must be a multiple of Nevery and Nevery must be non-zero even if Nfreq is 1. Also, the timesteps contributing to the average value cannot overlap, i.e. Nrepeat*Nevery can not exceed Nfreq.

For example, if Nevery=2, Nrepeat=6, and Nfreq=100, then values on timesteps 90,92,94,96,98,100 will be used to compute the final average on timestep 100. Similarly for timesteps 190,192,194,196,198,200 on timestep 200, etc.

The atom attribute values (x,y,z,vx,vy,vz,fx,fy,fz) are self-explanatory. Note that other atom attributes can be used as inputs to this fix by using the compute property/atom command and then specifying an input value from that compute.

Note: The x,y,z attributes are values that are re-wrapped inside the periodic box whenever an atom crosses a periodic boundary. Thus if you time average an atom that spends half its time on either side of the periodic box, you will get a value in the middle of the box. If this is not what you want, consider averaging unwrapped coordinates, which can be provided by the compute property/atom command via its xu,yu,zu attributes.

If a value begins with "c_", a compute ID must follow which has been previously defined in the input script. If no bracketed term is appended, the per-atom vector calculated by the compute is used. If a bracketed term containing an
index I is appended, the Ith column of the per-atom array calculated by the compute is used. Users can also write code for their own compute styles and *add them to LAMMPS*. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “f_”, a fix ID must follow which has been previously defined in the input script. If no bracketed term is appended, the per-atom vector calculated by the fix is used. If a bracketed term containing an index I is appended, the Ith column of the per-atom array calculated by the fix is used. Note that some fixes only produce their values on certain timesteps, which must be compatible with Nevery, else an error will result. Users can also write code for their own fix styles and *add them to LAMMPS*. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “v_”, a variable name must follow which has been previously defined in the input script as an *atom-style variable*. Variables of style atom can reference thermodynamic keywords, or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of generating per-atom quantities to time average.

**17.10.4 Restart, fix_modify, output, run start/stop, minimize info**

No information about this fix is written to *binary restart files*. None of the *fix_modify* options are relevant to this fix. No global scalar or vector quantities are stored by this fix for access by various *output commands*.

This fix produces a per-atom vector or array which can be accessed by various *output commands*. A vector is produced if only a single quantity is averaged by this fix. If two or more quantities are averaged, then an array of values is produced. The per-atom values can only be accessed on timesteps that are multiples of Nfreq since that is when averaging is performed.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

   string = text to print as 2nd line of output file
title3 arg = string
   string = text to print as 3rd line of output file
17.11.2 Examples

```plaintext
fix 1 all ave/chunk 10000 1 10000 binchunk c_myCentro title1 "My output values"
fix 1 flow ave/chunk 100 10 1000 molchunk vx vz norm sample file vel.profile
define c1 = e_max
fix 1 define c2 2.0 timescale 1.0
fix 1 flow ave/chunk 100 10 1000 binchunk density/mass ave running
define c3 = c1 + c2
fix 1 flow ave/chunk 100 10 1000 binchunk density/mass ave running
```

NOTE:

If you are trying to replace a deprecated fix ave/spatial command with the newer, more flexible fix ave/chunk and compute chunk/atom commands, you simply need to split the fix ave/spatial arguments across the two new commands. For example, this command:

```plaintext
fix 1 flow ave/spatial 100 10 1000 y 0.0 1.0 vx vz norm sample file vel.profile
```

could be replaced by:

```plaintext
compute c1 flow chunk/atom bin/1d y 0.0 1.0
fix 1 flow ave/chunk 100 10 1000 c1 vx vz norm sample file vel.profile
```

17.11.3 Description

Use one or more per-atom vectors as inputs every few timesteps, sum the values over the atoms in each chunk at each timestep, then average the per-chunk values over longer timescales. The resulting chunk averages can be used by other output commands such as thermo_style custom, and can also be written to a file.

In LAMMPS, chunks are collections of atoms defined by a compute chunk/atom command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the compute chunk/atom page and the Howto chunk page for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

Note that only atoms in the specified group contribute to the summing and averaging calculations. The compute chunk/atom command defines its own group as well as an optional region. Atoms will have a chunk ID = 0, meaning they belong to no chunk, if they are not in that group or region. Thus you can specify the “all” group for this command if you simply want to use the chunk definitions provided by chunkID.

Each specified per-atom value can be an atom attribute (position, velocity, force component), a mass or number density, or the result of a compute or fix or the evaluation of an atom-style variable. In the latter cases, the compute, fix, or variable must produce a per-atom quantity, not a global quantity. Note that the compute property/atom command provides access to any attribute defined and stored by atoms. If you wish to time-average global quantities from a compute, fix, or variable, then see the fix ave/time command.

The per-atom values of each input vector are summed and averaged independently of the per-atom values in other input vectors.

Computes that produce per-atom quantities are those which have the word `atom` in their style name. See the doc pages for individual fixes to determine which ones produce per-atom quantities. Variables of style `atom` are the only ones that can be used with this fix since all other styles of variable produce global quantities.

Note that for values from a compute or fix, the bracketed index I can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “*” or “*n” or “n*” or “m*n”. If N = the size of the vector (for `mode` = scalar) or the number of columns in the array (for `mode` = vector), then an asterisk with no numeric values means all indices from 1 to N. A leading asterisk means all indices from 1 to n (inclusive). A trailing asterisk means all indices from n to N (inclusive). A middle asterisk means all indices from m to n (inclusive).
Using a wildcard is the same as if the individual columns of the array had been listed one by one. E.g. these 2 fix ave/chunk commands are equivalent, since the compute property/atom command creates, in this case, a per-atom array with 3 columns:

```
compute myAng all property/atom angmomx angmomy angmomz
fix 1 all ave/chunk 100 1 100 c_myAng[*] file tmp.angmom
```

**Note:** This fix works by creating an array of size Nchunk by Nvalues on each processor. Nchunk is the number of chunks which is defined by the compute chunk/atom command. Nvalues is the number of input values specified. Each processor loops over its atoms, tallying its values to the appropriate chunk. Then the entire array is summed across all processors. This means that using a large number of chunks will incur an overhead in memory and computational cost (summing across processors), so be careful to define a reasonable number of chunks.

The Nevery, Nrepeat, and Nfreq arguments specify on what timesteps the input values will be accessed and contribute to the average. The final averaged quantities are generated on timesteps that are a multiples of Nfreq. The average is over Nrepeat quantities, computed in the preceding portion of the simulation every Nevery timesteps. Nfreq must be a multiple of Nevery and Nevery must be non-zero even if Nrepeat is 1. Also, the timesteps contributing to the average value cannot overlap, i.e. Nrepeat*Nevery can not exceed Nfreq.

For example, if Nevery=2, Nrepeat=6, and Nfreq=100, then values on timesteps 90,92,94,96,98,100 will be used to compute the final average on timestep 100. Similarly for timesteps 190,192,194,196,198,200 on timestep 200, etc. If Nrepeat=1 and Nfreq = 100, then no time averaging is done; values are simply generated on timesteps 100,200,etc.

Each input value can also be averaged over the atoms in each chunk. The way the averaging is done across the Nrepeat timesteps to produce output on the Nfreq timesteps, and across multiple Nfreq outputs, is determined by the norm and ave keyword settings, as discussed below.

**Note:** To perform per-chunk averaging within a Nfreq time window, the number of chunks Nchunk defined by the compute chunk/atom command must remain constant. If the ave keyword is set to running or window then Nchunk must remain constant for the duration of the simulation. This fix forces the chunk/atom compute specified by chunkID to hold Nchunk constant for the appropriate time windows, by not allowing it to re-calculate Nchunk, which can also affect how it assigns chunk IDs to atoms. This is particularly important to understand if the chunks defined by the compute chunk/atom command are spatial bins. If its units keyword is set to box or lattice, then the number of bins Nchunk and size of each bin will be fixed over the Nfreq time window, which can affect which atoms are discarded if the simulation box size changes. If its units keyword is set to reduced, then the number of bins Nchunk will still be fixed, but the size of each bin can vary at each timestep if the simulation box size changes, e.g. for an NPT simulation.

The atom attribute values (vx,vy,vz,fx,fy,fz) are self-explanatory. As noted above, any other atom attributes can be used as input values to this fix by using the compute property/atom command and then specifying an input value from that compute.

The density/number value means the number density is computed for each chunk, i.e. number/volume. The density/mass value means the mass density is computed for each chunk, i.e. total-mass/volume. The output values are in units of 1/volume or density (mass/volume). See the units command page for the definition of density for each choice of units, e.g. gram/cm^3. If the chunks defined by the compute chunk/atom command are spatial bins, the volume is the bin volume. Otherwise it is the volume of the entire simulation box.

The temp value means the temperature is computed for each chunk, by the formula KE = DOF/2 k T, where KE = total kinetic energy of the chunk of atoms (sum of 1/2 m v^2), DOF = the total number of degrees of freedom for all atoms in the chunk, k = Boltzmann constant, and T = temperature.
The DOF is calculated as $N \times \text{adof} + \text{cdof}$, where $N$ = number of atoms in the chunk, $\text{adof}$ = degrees of freedom per atom, and $\text{cdof}$ = degrees of freedom per chunk. By default $\text{adof} = 2$ or 3 = dimensionality of system, as set via the \texttt{dimension} command, and $\text{cdof} = 0.0$. This gives the usual formula for temperature.

Note that currently this temperature only includes translational degrees of freedom for each atom. No rotational degrees of freedom are included for finite-size particles. Also no degrees of freedom are subtracted for any velocity bias or constraints that are applied, such as \texttt{compute temp/partial}, or \texttt{fix shake} or \texttt{fix rigid}. This is because those degrees of freedom (e.g. a constrained bond) could apply to sets of atoms that are both included and excluded from a specific chunk, and hence the concept is somewhat ill-defined. In some cases, you can use the $\text{adof}$ and $\text{cdof}$ keywords to adjust the calculated degrees of freedom appropriately, as explained below.

Also note that a bias can be subtracted from atom velocities before they are used in the above formula for KE, by using the \texttt{bias} keyword. This allows, for example, a thermal temperature to be computed after removal of a flow velocity profile.

Note that the per-chunk temperature calculated by this fix and the \texttt{compute temp/chunk} command can be different. The compute calculates the temperature for each chunk for a single snapshot. This fix can do that but can also time average those values over many snapshots, or it can compute a temperature as if the atoms in the chunk on different timesteps were collected together as one set of atoms to calculate their temperature. The compute allows the center-of-mass velocity of each chunk to be subtracted before calculating the temperature; this fix does not.

If a value begins with \texttt{“c”}, a compute ID must follow which has been previously defined in the input script. If no bracketed integer is appended, the per-atom vector calculated by the compute is used. If a bracketed integer is appended, the $I$th column of the per-atom array calculated by the compute is used. Users can also write code for their own compute styles and \texttt{add them to LAMMPS}. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with \texttt{“f”}, a fix ID must follow which has been previously defined in the input script. If no bracketed integer is appended, the per-atom vector calculated by the fix is used. If a bracketed integer is appended, the $I$th column of the per-atom array calculated by the fix is used. Note that some fixes only produce their values on certain timesteps, which must be compatible with \texttt{Nevery}, else an error results. Users can also write code for their own fix styles and \texttt{add them to LAMMPS}. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with \texttt{“v”}, a variable name must follow which has been previously defined in the input script. Variables of style \texttt{atom} can reference thermodynamic keywords and various per-atom attributes, or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of generating per-atom quantities to average within chunks.

Additional optional keywords also affect the operation of this fix and its outputs.

The \texttt{norm} keyword affects how averaging is done for the per-chunk values that are output every $N_{freq}$ timesteps.

If the \texttt{norm} setting is \texttt{all}, which is the default, a chunk value is summed over all atoms in all $N_{repeat}$ samples, as is the count of atoms in the chunk. The averaged output value for the chunk on the $N_{freq}$ timesteps is Total-sum / Total-count. In other words it is an average over atoms across the entire $N_{freq}$ timescale. For the $\texttt{density/number}$ and $\texttt{density/mass}$ values, the volume (bin volume or system volume) used in the final normalization will be the volume at the final $N_{freq}$ timestep. For the $\texttt{temp}$ values, degrees of freedom and kinetic energy are summed separately across the entire $N_{freq}$ timescale, and the output value is calculated by dividing those two sums.

If the \texttt{norm} setting is \texttt{sample}, the chunk value is summed over atoms for each sample, as is the count, and an “average sample value” is computed for each sample, i.e. Sample-sum / Sample-count. The output value for the chunk on the $N_{freq}$ timesteps is the average of the $N_{repeat}$ “average sample values”, i.e. the sum of $N_{repeat}$ “average sample values” divided by $N_{repeat}$. In other words it is an average of an average. For the $\texttt{density/number}$ and $\texttt{density/mass}$ values, the volume (bin volume or system volume) used in the per-sample normalization will be the current volume at each sampling step.
If the norm setting is none, a similar computation as for the sample setting is done, except the individual “average sample values” are “summed sample values”. A summed sample value is simply the chunk value summed over atoms in the sample, without dividing by the number of atoms in the sample. The output value for the chunk on the Nfreq timesteps is the average of the Nrepeat “summed sample values”, i.e., the sum of Nrepeat “summed sample values” divided by Nrepeat. For the density/number and density/mass values, the volume (bin volume or system volume) used in the per-sample sum normalization will be the current volume at each sampling step.

The ave keyword determines how the per-chunk values produced every Nfreq steps are averaged with values produced on previous steps that were multiples of Nfreq, before they are accessed by another output command or written to a file.

If the ave setting is one, which is the default, then the chunk values produced on timesteps that are multiples of Nfreq are independent of each other; they are output as-is without further averaging.

If the ave setting is running, then the chunk values produced on timesteps that are multiples of Nfreq are summed and averaged in a cumulative sense before being output. Each output chunk value is thus the average of the chunk value produced on that timestep with all preceding values for the same chunk. This running average begins when the fix is defined; it can only be restarted by deleting the fix via the unfix command, or re-defining the fix by re-specifying it.

If the ave setting is window, then the chunk values produced on timesteps that are multiples of Nfreq are summed and averaged within a moving “window” of time, so that the last M values for the same chunk are used to produce the output. E.g. if M = 3 and Nfreq = 1000, then the output on step 10000 will be the average of the individual chunk values on steps 8000, 9000, 10000. Outputs on early steps will average over less than M values if they are not available.

The bias keyword specifies the ID of a temperature compute that removes a “bias” velocity from each atom, specified as bias-ID. It is only used when the temp value is calculated, to compute the thermal temperature of each chunk after the translational kinetic energy components have been altered in a prescribed way, e.g. to remove a flow velocity profile.

See the doc pages for individual computes that calculate a temperature to see which ones implement a bias.

The adof and cdof keywords define the values used in the degree of freedom (DOF) formula described above for temperature calculation for each chunk. They are only used when the temp value is calculated. They can be used to calculate a more appropriate temperature for some kinds of chunks. Here are 3 examples:

If spatially binned chunks contain some number of water molecules and fix shake is used to make each molecule rigid, then you could calculate a temperature with 6 degrees of freedom (DOF) (3 translational, 3 rotational) per molecule by setting adof to 2.0.

If compute temp/partial is used with the bias keyword to only allow the x component of velocity to contribute to the temperature, then adof = 1.0 would be appropriate.

If each chunk consists of a large molecule, with some number of its bonds constrained by fix shake or the entire molecule by fix rigid/small, adof = 0.0 and cdof could be set to the remaining degrees of freedom for the entire molecule (entire chunk in this case), e.g. 6 for 3d, or 3 for 2d, for a rigid molecule.

The file keyword allows a filename to be specified. Every Nfreq timesteps, a section of chunk info will be written to a text file in the following format. A line with the timestep and number of chunks is written. Then one line per chunk is written, containing the chunk ID (1-Nchunk), an optional original ID value, optional coordinate values for chunks that represent spatial bins, the number of atoms in the chunk, and one or more calculated values. More explanation of the optional values is given below. The number of values in each line corresponds to the number of values specified in the fix ave/chunk command. The number of atoms and the value(s) are summed or average quantities, as explained above.

The overwrite keyword will continuously overwrite the output file with the latest output, so that it only contains one timestep worth of output. This option can only be used with the ave running setting.

The format keyword sets the numeric format of each value when it is printed to a file via the file keyword. Note that all values are floating point quantities. The default format is %g. You can specify a higher precision if desired, e.g. %20.16g.

The title1 and title2 and title3 keywords allow specification of the strings that will be printed as the first 3 lines of the output file, assuming the file keyword was used. LAMMPS uses default values for each of these, so they do not need to be specified.
By default, these header lines are as follows:

```
# Chunk-averaged data for fix ID and group name
# Timestep Number-of-chunks
# Chunk (OrigID) (Coord1) (Coord2) (Coord3) Ncount value1 value2 ...
```

In the first line, ID and name are replaced with the fix-ID and group name. The second line describes the two values that are printed at the first of each section of output. In the third line the values are replaced with the appropriate value names, e.g. fx or c_myCompute[2].

The words in parenthesis only appear with corresponding columns if the chunk style specified for the `compute chunk/atom` command supports them. The OrigID column is only used if the `compress` keyword was set to `yes` for the `compute chunk/atom` command. This means that the original chunk IDs (e.g. molecule IDs) will have been compressed to remove chunk IDs with no atoms assigned to them. Thus a compressed chunk ID of 3 may correspond to an original chunk ID or molecule ID of 415. The OrigID column will list 415 for the third chunk.

The CoordN columns only appear if a `binning` style was used in the `compute chunk/atom` command. For `bin/1d`, `bin/2d`, and `bin/3d` styles the column values are the center point of the bin in the corresponding dimension. Just Coord1 is used for `bin/1d`, Coord2 is added for `bin/2d`, Coord3 is added for `bin/3d`. For `bin/sphere`, just Coord1 is used, and it is the radial coordinate. For `bin/cylinder`, Coord1 and Coord2 are used. Coord1 is the radial coordinate (away from the cylinder axis), and coord2 is the coordinate along the cylinder axis.

Note that if the value of the `units` keyword used in the `compute chunk/atom command` is `box` or `lattice`, the coordinate values will be in distance units. If the value of the `units` keyword is `reduced`, the coordinate values will be in unitless reduced units (0-1). This is not true for the Coord1 value of style `bin/sphere` or `bin/cylinder` which both represent radial dimensions. Those values are always in distance units.

### 17.11.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the `fix_modify` options are relevant to this fix.

This fix computes a global array of values which can be accessed by various `output` commands. The values can only be accessed on timesteps that are multiples of `Nfreq` since that is when averaging is performed. The global array has # of rows = the number of chunks `Nchunk` as calculated by the specified `compute chunk/atom` command. The # of columns = M+1+Nvalues, where M = 1 to 4, depending on whether the optional columns for OrigID and CoordN are used, as explained above. Following the optional columns, the next column contains the count of atoms in the chunk, and the remaining columns are the Nvalue quantities. When the array is accessed with a row I that exceeds the current number of chunks, than a 0.0 is returned by the fix instead of an error, since the number of chunks can vary as a simulation runs depending on how that value is computed by the compute chunk/atom command.

The array values calculated by this fix are treated as “intensive”, since they are typically already normalized by the count of atoms in each chunk.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during energy minimization.

17.12.2 Examples

```fix
1 all ave/correlate 5 100 1000 c_myTemp file temp.correlate
1 all ave/correlate 1 50 10000 &
  type upper ave running title1 "My correlation data"
1 all ave/correlate 1 50 10000 c_thermo_press[*]
```

17.12.3 Description

Use one or more global scalar values as inputs every few timesteps, calculate time correlations between them at varying time intervals, and average the correlation data over longer timescales. The resulting correlation values can be time integrated by variables or used by other output commands such as thermo_style custom, and can also be written to a file. See the fix ave/correlate/long command for an alternate method for computing correlation functions efficiently over very long time windows.

The group specified with this command is ignored. However, note that specified values may represent calculations performed by computes and fixes which store their own “group” definitions.

Each listed value can be the result of a compute or fix or the evaluation of an equal-style or vector-style variable. In each case, the compute, fix, or variable must produce a global quantity, not a per-atom or local quantity. If you wish to spatial- or time-average or histogram per-atom quantities from a compute, fix, or variable, then see the fix ave/chunk, fix ave/atom, or fix ave/histo commands. If you wish to convert a per-atom quantity into a single global value, see the compute reduce command.

The input values must be all scalars. What kinds of correlations between input values are calculated is determined by the type keyword as discussed below.

**Computes** that produce global quantities are those which do not have the word atom in their style name. Only a few fixes produce global quantities. See the doc pages for individual fixes for info on which ones produce such values. **Variables** of style equal and vector are the only ones that can be used with this fix. Variables of style atom cannot be used, since they produce per-atom values.

For input values from a compute or fix or variable, the bracketed index I can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “*” or “*n” or “n*” or “m*n”. If N = the
size of the vector, then an asterisk with no numeric values means all indices from 1 to N. A leading asterisk means all indices from 1 to n (inclusive). A trailing asterisk means all indices from n to N (inclusive). A middle asterisk means all indices from m to n (inclusive).

Using a wildcard is the same as if the individual elements of the vector had been listed one by one. E.g. these 2 fix ave/correlate commands are equivalent, since the `compute pressure` command creates a global vector with 6 values.

```plaintext
compute myPress all pressure NULL
fix 1 all ave/correlate 1 50 10000 c_myPress[*]
fix 1 all ave/correlate 1 50 10000 &
```

**Note:** For a vector-style variable, only the wildcard forms “*n” or “m*n” are allowed. You must specify the upper bound, because vector-style variable lengths are not determined until the variable is evaluated. If n is specified larger than the vector length turns out to be, zeroes are output for missing vector values.

The `Nevery`, `Nrepeat`, and `Nfreq` arguments specify on what timesteps the input values will be used to calculate correlation data. The input values are sampled every `Nevery` timesteps. The correlation data for the preceding samples is computed on timesteps that are a multiple of `Nfreq`. Consider a set of samples from some initial time up to an output timestep. The initial time could be the beginning of the simulation or the last output time; see the `ave` keyword for options. For the set of samples, the correlation value $C_{ij}$ is calculated as:

$$C_{ij}(\delta) = \text{ave}(V_i(t) * V_j(t+\delta))$$

which is the correlation value between input values $V_i$ and $V_j$, separated by time delta. Note that the second value $V_j$ in the pair is always the one sampled at the later time. The `ave()` represents an average over every pair of samples in the set that are separated by time delta. The maximum delta used is of size $(Nrepeat-1)\times Nevery$. Thus the correlation between a pair of input values yields $Nrepeat$ correlation datums:

$$C_{ij}(0), C_{ij}(Nevery), C_{ij}(2*Nevery), \ldots, C_{ij}((Nrepeat-1)*Nevery)$$

For example, if `Nevery`=5, `Nrepeat`=6, and `Nfreq`=100, then values on timesteps 0,5,10,15...,100 will be used to compute the final averages on timestep 100. Six averages will be computed: $C_{ij}(0)$, $C_{ij}(5)$, $C_{ij}(10)$, $C_{ij}(15)$, $C_{ij}(20)$, and $C_{ij}(25)$. $C_{ij}(10)$ on timestep 100 will be the average of 19 samples, namely $V_i(0)\times V_j(10)$, $V_i(5)\times V_j(15)$, $V_i(10)\times V_j(20)$, $V_i(15)\times V_j(25)$, ..., $V_i(85)\times V_j(95)$, $V_i(90)\times V_j(100)$. 

`Nfreq` must be a multiple of `Nevery`; `Nevery` and `Nrepeat` must be non-zero. Also, if the `ave` keyword is set to `one` which is the default, then `Nfreq` must be larger than or equal to $(Nrepeat-1)\times Nevery$.

If a value begins with “c_”, a compute ID must follow which has been previously defined in the input script. If no bracketed term is appended, the global scalar calculated by the compute is used. If a bracketed term is appended, the Ith element of the global vector calculated by the compute is used. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

Note that there is a `compute reduce` command which can sum per-atom quantities into a global scalar or vector which can thus be accessed by fix ave/correlate. Or it can be a compute defined not in your input script, but by thermodynamic output or other fixes such as `fix nvt` or `fix temp/rescale`. See the doc pages for these commands which give the IDs of these computes. Users can also write code for their own compute styles and add them to LAMMPS.

If a value begins with “f_”, a fix ID must follow which has been previously defined in the input script. If no bracketed term is appended, the global scalar calculated by the fix is used. If a bracketed term is appended, the Ith element of the global vector calculated by the fix is used. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

1090  Chapter 17. Fixes
Note that some fixes only produce their values on certain timesteps, which must be compatible with Nevery, else an error will result. Users can also write code for their own fix styles and add them to LAMMPS.

If a value begins with “v_”, a variable name must follow which has been previously defined in the input script. Only equal-style or vector-style variables can be referenced; the latter requires a bracketed term to specify the Ith element of the vector calculated by the variable. See the variable command for details. Note that variables of style equal or vector define a formula which can reference individual atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of specifying quantities to time correlate.

Additional optional keywords also affect the operation of this fix.

The type keyword determines which pairs of input values are correlated with each other. For N input values Vi, for i = 1 to N, let the number of pairs = Npair. Note that the second value in the pair Vi(t) * Vj(t+delta) is always the one sampled at the later time.

- If type is set to auto then each input value is correlated with itself. I.e. Cii = Vi * Vi, for i = 1 to N, so Npair = N.
- If type is set to upper then each input value is correlated with every succeeding value. I.e. Cij = Vi * Vj, for i < j, so Npair = N*(N-1)/2.
- If type is set to lower then each input value is correlated with every preceding value. I.e. Cij = Vi * Vj, for i > j, so Npair = N*(N-1)/2.
- If type is set to auto/upper then each input value is correlated with itself and every succeeding value. I.e. Cij = Vi * Vj, for i >= j, so Npair = N*(N+1)/2.
- If type is set to auto/lower then each input value is correlated with itself and every preceding value. I.e. Cij = Vi * Vj, for i <= j, so Npair = N*(N+1)/2.
- If type is set to full then each input value is correlated with itself and every other value. I.e. Cij = Vi * Vj, for i,j = 1,N so Npair = N^2.

The ave keyword determines what happens to the accumulation of correlation samples every Nfreq timesteps. If the ave setting is one, then the accumulation is restarted or zeroed every Nfreq timesteps. Thus the outputs on successive Nfreq timesteps are essentially independent of each other. The exception is that the Cij(0) = Vi(T) * Vj(T) value at a timestep T, where T is a multiple of Nfreq, contributes to the correlation output both at time T and at time T+Nfreq.

If the ave setting is running, then the accumulation is never zeroed. Thus the output of correlation data at any timestep is the average over samples accumulated every Nevery steps since the fix was defined. it can only be restarted by deleting the fix via the unfix command, or by re-defining the fix by re-specifying it.

The start keyword specifies what timestep the accumulation of correlation samples will begin on. The default is step 0. Setting it to a larger value can avoid adding non-equilibrated data to the correlation averages.

The prefactor keyword specifies a constant which will be used as a multiplier on the correlation data after it is averaged. It is effectively a scale factor on Vi * Vj, which can be used to account for the size of the time window or other unit conversions.

The file keyword allows a filename to be specified. Every Nfreq steps, an array of correlation data is written to the file. The number of rows is Nrepeat, as described above. The number of columns is the Npair+2, also as described above. Thus the file ends up to be a series of these array sections.

The overwrite keyword will continuously overwrite the output file with the latest output, so that it only contains one timestep worth of output. This option can only be used with the ave running setting.

The title1 and title2 and title3 keywords allow specification of the strings that will be printed as the first 3 lines of the output file, assuming the file keyword was used. LAMMPS uses default values for each of these, so they do not need to be specified.

By default, these header lines are as follows:
# Time-correlated data for fix ID
# TimeStep Number-of-time-windows
# Index TimeDelta Ncount valueI*valueJ valueI*valueJ ...

In the first line, ID is replaced with the fix-ID. The second line describes the two values that are printed at the first of each section of output. In the third line the value pairs are replaced with the appropriate fields from the fix ave/correlate command.

Let $S_{ij}$ = a set of time correlation data for input values I and J, namely the $N_{repeat}$ values:

$$S_{ij} = C_{ij}(0), C_{ij}(N_{every}), C_{ij}(2*N_{every}), \ldots, C_{ij}(*N_{repeat}-1)*N_{every})$$

As explained below, these datums are output as one column of a global array, which is effectively the correlation matrix. The trap function defined for equal-style variables can be used to perform a time integration of this vector of datums, using a trapezoidal rule. This is useful for calculating various quantities which can be derived from time correlation data. If a normalization factor is needed for the time integration, it can be included in the variable formula or via the prefactor keyword.

### 17.12.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix.

This fix computes a global array of values which can be accessed by various output commands. The values can only be accessed on timesteps that are multiples of $N_{freq}$ since that is when averaging is performed. The global array has # of rows = $N_{repeat}$ and # of columns = $N_{pair}+2$. The first column has the time delta (in timesteps) between the pairs of input values used to calculate the correlation, as described above. The second column has the number of samples contributing to the correlation average, as described above. The remaining $N_{pair}$ columns are for I,J pairs of the $N$ input values, as determined by the type keyword, as described above.

- For type = auto, the $N_{pair}$ = $N$ columns are ordered: C11, C22, ..., CNN.
- For type = upper, the $N_{pair}$ = $N*(N-1)/2$ columns are ordered: C12, C13, ..., C1N, C23, ..., C2N, C34, ..., CN-1N.
- For type = lower, the $N_{pair}$ = $N*(N-1)/2$ columns are ordered: C21, C31, C32, C41, C42, C43, ..., CN1, CN2, ..., CNN-1.
- For type = auto/upper, the $N_{pair}$ = $N*(N+1)/2$ columns are ordered: C11, C12, C13, ..., C1N, C22, C23, ..., C2N, C33, C34, ..., CN-1N, CNN.
- For type = auto/lower, the $N_{pair}$ = $N*(N+1)/2$ columns are ordered: C11, C21, C22, C31, C32, C33, C41, ..., C44, CN1, CN2, ..., CNN-1, CNN.
- For type = full, the $N_{pair}$ = $N^2$ columns are ordered: C11, C12, ..., C1N, C21, C22, ..., C2N, C31, ..., C3N, ..., CN1, ..., CNN-1, CNN.

The array values calculated by this fix are treated as intensive. If you need to divide them by the number of atoms, you must do this in a later processing step, e.g. when using them in a variable.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

    Ncorrelators = number of correlators to store
nlen args = Nlen
    Nlen = length of each correlator
ncount args = Ncount
    Ncount = number of values over which successive correlators are averaged

17.13.2 Examples

fix 1 all ave/correlate/long 5 1000 c_myTemp file temp.correlate
fix 1 all ave/correlate/long 1 10000 &
    type upper title1 "My correlation data" nlen 15 ncount 3

17.13.3 Description

This fix is similar in spirit and syntax to the fix ave/correlate. However, this fix allows the efficient calculation of time correlation functions on-the-fly over extremely long time windows with little additional CPU overhead, using a multiple-tau method (Ramirez) that decreases the resolution of the stored correlation function with time. It is not a full drop-in replacement.

The group specified with this command is ignored. However, note that specified values may represent calculations performed by computes and fixes which store their own “group” definitions.

Each listed value can be the result of a compute or fix or the evaluation of an equal-style variable. See the fix ave/correlate page for details.

The Nevery and Nfreq arguments specify on what timesteps the input values will be used to calculate correlation data, and the frequency with which the time correlation functions will be output to a file. Note that there is no Nrepeat argument, unlike the fix ave/correlate command.

The optional keywords ncorr, nlen, and ncount are unique to this command and determine the number of correlation points calculated and the memory and CPU overhead used by this calculation. Nlen and ncount determine the amount of averaging done at longer correlation times. The default values nlen=16, ncount=2 ensure that the systematic error of the multiple-tau correlator is always below the level of the statistical error of a typical simulation (which depends on the ensemble size and the simulation length).

The maximum correlation time (in time steps) that can be reached is given by the formula \((nlen-1) \times ncount^{(ncorr-1)}\). Longer correlation times are discarded and not calculated. With the default values of the parameters (ncorr=20, nlen=16 and ncount=2), this corresponds to 7864320 time steps. If longer correlation times are needed, the value of ncorr should be increased. Using nlen=16 and ncount=2, with ncorr=30, the maximum number of steps that can be correlated is 80530636808. If ncorr=40, correlation times in excess of 8e12 time steps can be calculated.

The total memory needed for each correlation pair is roughly 4*ncorr*nlen*8 bytes. With the default values of the parameters, this corresponds to about 10 KB.

For the meaning of the additional optional keywords, see the fix ave/correlate doc page.
17.13.4 Restart, fix_modify, output, run start/stop, minimize info

Contrary to fix ave/correlate this fix does not provide access to its internal data to various output options. Since this fix is intended for the calculation of time correlation functions over very long MD simulations, the information about this fix is written automatically to binary restart files, so that the time correlation calculation can continue in subsequent simulations. None of the fix_modify options are relevant to this fix.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.13.5 Restrictions

This compute is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

\]
17.15.3 Description

Use one or more values as inputs every few timesteps to create a single histogram. The histogram can then be averaged over longer timescales. The resulting histogram can be used by other output commands, and can also be written to a file. The fix ave/histo/weight command has identical syntax to fix ave/histo, except that exactly two values must be specified. See details below.

The group specified with this command is ignored for global and local input values. For per-atom input values, only atoms in the group contribute to the histogram. Note that regardless of the specified group, specified values may represent calculations performed by computes and fixes which store their own “group” definition.

A histogram is simply a count of the number of values that fall within a histogram bin. Nbins are defined, with even spacing between lo and hi. Values that fall outside the lo/hi bounds can be treated in different ways; see the discussion of the beyond keyword below.

Each input value can be an atom attribute (position, velocity, force component) or can be the result of a compute or fix or the evaluation of an equal-style or vector-style or atom-style variable. The set of input values can be either all global, all per-atom, or all local quantities. Inputs of different kinds (e.g. global and per-atom) cannot be mixed. Atom attributes are per-atom vector values. See the page for individual “compute” and “fix” commands to see what kinds of quantities they generate. See the optional kind keyword below for how to force the fix ave/histo command to disambiguate if necessary.

Note that the output of this command is a single histogram for all input values combined together, not one histogram per input value. See below for details on the format of the output of this fix.

The input values must either be all scalars or all vectors (or arrays), depending on the setting of the mode keyword.

If mode = scalar, then the input values must be scalars, or vectors with a bracketed term appended, indicating the Ith value of the vector is used.

If mode = vector, then the input values must be vectors, or arrays with a bracketed term appended, indicating the Ith column of the array is used.

If the fix ave/histo/weight command is used, exactly two values must be specified. If the values are vectors, they must be the same length. The first value (a scalar or vector) is what is histogrammed into bins, in the same manner the fix ave/histo command operates. The second value (a scalar or vector) is used as a “weight”. This means that instead of each value tallying a “1” to its bin, the corresponding weight is tallied. E.g. The Nth entry (weight) in the second vector is tallied to the bin corresponding to the Nth entry in the first vector.

For input values from a compute or fix or variable, the bracketed index I can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “*n” or “*n” or “*n” or “m*n”. If N = the size of the vector (for mode = scalar) or the number of columns in the array (for mode = vector), then an asterisk with no numeric values means all indices from 1 to N. A leading asterisk means all indices from 1 to n (inclusive). A trailing asterisk means all indices from n to N (inclusive). A middle asterisk means all indices from m to n (inclusive).

Using a wildcard is the same as if the individual elements of the vector or columns of the array had been listed one by one. E.g. these 2 fix ave/histo commands are equivalent, since the compute com/chunk command creates a global array with 3 columns:

```
compute myCOM all com/chunk
fix 1 all ave/histo 100 1 100 10.0 10.0 100 c_myCOM[*] file tmp1.com mode vector
```

Note: For a vector-style variable, only the wildcard forms “*n” or “m*n” are allowed. You must specify the upper bound, because vector-style variable lengths are not determined until the variable is evaluated. If n is specified larger
than the vector length turns out to be, zeroes are output for missing vector values.

The Nevery, Nrepeat, and Nfreq arguments specify on what timesteps the input values will be used in order to contribute to the histogram. The final histogram is generated on timesteps that are multiple of Nfreq. It is averaged over Nrepeat histograms, computed in the preceding portion of the simulation every Nevery timesteps. Nfreq must be a multiple of Nevery and Nevery must be non-zero even if Nrepeat is 1. Also, the timesteps contributing to the histogram value cannot overlap, i.e. Nrepeat*Nevery cannot exceed Nfreq.

For example, if Nevery=2, Nrepeat=6, and Nfreq=100, then input values on timesteps 90,92,94,96,98,100 will be used to compute the final histogram on timestep 100. Similarly for timesteps 190,192,194,196,198,200 on timestep 200, etc. If Nrepeat=1 and Nfreq = 100, then no time averaging of the histogram is done; a histogram is simply generated on timesteps 100,200,etc.

The atom attribute values (x,y,z,vx,vy,vz,fx,fy,fz) are self-explanatory. Note that other atom attributes can be used as inputs to this fix by using the compute property/atom command and then specifying an input value from that compute.

If a value begins with “c_”, a compute ID must follow which has been previously defined in the input script. If mode = scalar, then if no bracketed term is appended, the global scalar calculated by the compute is used. If a bracketed term is appended, the Ith element of the global vector calculated by the compute is used. If mode = vector, then if no bracketed term is appended, the global or per-atom or local vector calculated by the compute is used. If a bracketed term is appended, the Ith column of the global or per-atom or local array calculated by the compute is used. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

Note that there is a compute reduce command which can sum per-atom quantities into a global scalar or vector which can thus be accessed by fix ave/histo. Or it can be a compute defined not in your input script, but by thermodynamic output or other fixes such as fix nvt or fix temp/rescale. See the doc pages for these commands which give the IDs of these computes. Users can also write code for their own compute styles and add them to LAMMPS.

If a value begins with “f_”, a fix ID must follow which has been previously defined in the input script. If mode = scalar, then if no bracketed term is appended, the global scalar calculated by the fix is used. If a bracketed term is appended, the Ith element of the global vector calculated by the fix is used. If mode = vector, then if no bracketed term is appended, the global or per-atom or local vector calculated by the fix is used. If a bracketed term is appended, the Ith column of the global or per-atom or local array calculated by the fix is used. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

Note that some fixes only produce their values on certain timesteps, which must be compatible with Nevery, else an error will result. Users can also write code for their own fix styles and add them to LAMMPS.

If a value begins with “v_”, a variable name must follow which has been previously defined in the input script. If mode = scalar, then only equal-style or vector-style variables can be used, which both produce global values. In this mode, a vector-style variable requires a bracketed term to specify the Ith element of the vector calculated by the variable. If mode = vector, then only vector-style or atom-style variables can be used, which produce a global or per-atom vector respectively. The vector-style variable must be used without a bracketed term. See the variable command for details.

Note that variables of style equal, vector, and atom define a formula which can reference individual atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of specifying quantities to histogram.

Additional optional keywords also affect the operation of this fix.

If the mode keyword is set to scalar, then all input values must be global scalars, or elements of global vectors. If the mode keyword is set to vector, then all input values must be global or per-atom or local vectors, or columns of global or per-atom or local arrays.
The `kind` keyword only needs to be set if a compute or fix produces more than one kind of output (global, per-atom, local). If this is not the case, then LAMMPS will determine what kind of input is provided and whether all the input arguments are consistent. If a compute or fix produces more than one kind of output, the `kind` keyword should be used to specify which output will be used. The remaining input arguments must still be consistent.

The `beyond` keyword determines how input values that fall outside the `lo` to `hi` bounds are treated. Values such that `lo` <= value <= `hi` are assigned to one bin. Values on a bin boundary are assigned to the lower of the 2 bins. If `beyond` is set to `ignore` then values < `lo` and values > `hi` are ignored, i.e. they are not binned. If `beyond` is set to `end` then values < `lo` are counted in the first bin and values > `hi` are counted in the last bin. If `beyond` is set to `extend` then two extra bins are created, so that there are Nbins+2 total bins. Values < `lo` are counted in the first bin and values > `hi` are counted in the last bin (Nbins+2). Values between `lo` and `hi` (inclusive) are counted in bins 2 through Nbins+1. The “coordinate” stored and printed for these two extra bins is `lo` and `hi`.

The `ave` keyword determines how the histogram produced every `Nfreq` steps are averaged with histograms produced on previous steps that were multiples of `Nfreq`, before they are accessed by another output command or written to a file.

If the `ave` setting is `one`, then the histograms produced on timesteps that are multiples of `Nfreq` are independent of each other; they are output as-is without further averaging.

If the `ave` setting is `running`, then the histograms produced on timesteps that are multiples of `Nfreq` are summed and averaged in a cumulative sense before being output. Each bin value in the histogram is thus the average of the bin value produced on that timestep with all preceding values for the same bin. This running average begins when the fix is defined; it can only be restarted by deleting the fix via the `unfix` command, or by re-defining the fix by re-specifying it.

If the `ave` setting is `window`, then the histograms produced on timesteps that are multiples of `Nfreq` are summed within a moving “window” of time, so that the last M histograms are used to produce the output. E.g. if M = 3 and Nfreq = 1000, then the output on step 10000 will be the combined histogram of the individual histograms on steps 8000,9000,10000. Outputs on early steps will be sums over less than M histograms if they are not available.

The `start` keyword specifies what timestep histogramming will begin on. The default is step 0. Often input values can be 0.0 at time 0, so setting `start` to a larger value can avoid including a 0.0 in a running or windowed histogram.

The `file` keyword allows a filename to be specified. Every `Nfreq` steps, one histogram is written to the file. This includes a leading line that contains the timestep, number of bins, the total count of values contributing to the histogram, the count of values that were not histogrammed (see the `beyond` keyword), the minimum value encountered, and the maximum value encountered. The min/max values include values that were not histogrammed. Following the leading line, one line per bin is written into the file. Each line contains the bin #, the coordinate for the center of the bin (between `lo` and `hi`), the count of values in the bin, and the normalized count. The normalized count is the bin count divided by the total count (not including values not histogrammed), so that the normalized values sum to 1.0 across all bins.

The `overwrite` keyword will continuously overwrite the output file with the latest output, so that it only contains one timestep worth of output. This option can only be used with the `ave running` setting.

The `title1`, `title2` and `title3` keywords allow specification of the strings that will be printed as the first 3 lines of the output file, assuming the `file` keyword was used. LAMMPS uses default values for each of these, so they do not need to be specified.

By default, these header lines are as follows:

```
# Histogram for fix ID
# TimeStep Number-of-bins Total-counts Missing-counts Min-value Max-value
# Bin Coord Count Count/Total
```

In the first line, ID is replaced with the fix-ID. The second line describes the six values that are printed at the first of each section of output. The third describes the 4 values printed for each bin in the histogram.
17.15.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix.

This fix produces a global vector and global array which can be accessed by various output commands. The values can only be accessed on timesteps that are multiples of \( Nfreq \) since that is when a histogram is generated. The global vector has 4 values:

- 1 = total counts in the histogram
- 2 = values that were not histogrammed (see beyond keyword)
- 3 = min value of all input values, including ones not histogrammed
- 4 = max value of all input values, including ones not histogrammed

The global array has \# of rows = \( Nbins \) and \# of columns = 3. The first column has the bin coordinate, the second column has the count of values in that histogram bin, and the third column has the bin count divided by the total count (not including missing counts), so that the values in the third column sum to 1.0.

The vector and array values calculated by this fix are all treated as intensive. If this is not the case, e.g. due to histogramming per-atom input values, then you will need to account for that when interpreting the values produced by this fix.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.15.5 Restrictions

none

17.15.6 Related commands

compute, fix ave/atom, fix ave/chunk, fix ave/time, variable, fix ave/correlate,

17.15.7 Default

none

The option defaults are mode = scalar, kind = figured out from input arguments, ave = one, start = 0, no file output, beyond = ignore, and title 1,2,3 = strings as described above.

17.16 fix ave/time command

17.16.1 Syntax

```
fix ID group-ID ave/time Nevery Nrepeat Nfreq value1 value2 ... keyword args ...
```

- ID, group-ID are documented in fix command
- ave/time = style name of this fix command
- Nevery = use input values every this many timesteps
- Nrepeat = \# of times to use input values for calculating averages
- \( N_{freq} \) = calculate averages every this many timesteps
- one or more input values can be listed
- value = \( c_{ID}, c_{ID}[N], f_{ID}, f_{ID}[N], v_{name} \)
  
  \( c_{ID} = \) global scalar or vector calculated by a compute with ID
  
  \( c_{ID}[I] = \) Ith component of global vector or Ith column of global array calculated by a compute with ID, I can include wildcard (see below)

  \( f_{ID} = \) global scalar or vector calculated by a fix with ID
  
  \( f_{ID}[I] = \) Ith component of global vector or Ith column of global array calculated by a fix with ID, I can include wildcard (see below)

  \( v_{name} = \) value(s) calculated by an equal-style or vector-style variable with name
  
  \( v_{name}[I] = \) value calculated by a vector-style variable with name, I can include wildcard (see below)

- zero or more keyword/arg pairs may be appended
- keyword = \( mode \) or \( file \) or \( ave \) or \( start \) or \( off \) or \( overwrite \) or \( title1 \) or \( title2 \) or \( title3 \)

  \( mode \) arg = scalar or vector
  
  scalar = all input values are global scalars
  
  vector = all input values are global vectors or global arrays

  \( ave \) args = one or running or window \( M \)
  
  one = output a new average value every \( N_{freq} \) steps
  
  running = output cumulative average of all previous \( N_{freq} \) steps
  
  window \( M = \) output average of \( M \) most recent \( N_{freq} \) steps

  \( start \) args = \( N_{start} \)
  
  \( N_{start} = \) start averaging on this timestep

  \( off \) arg = \( M = \) do not average this value
  
  \( M = \) value # from 1 to \( N_{values} \)

  \( file \) arg = filename
  
  filename = name of file to output time averages to

  \( overwrite \) arg = none = overwrite output file with only latest output

  \( format \) arg = string
  
  string = C-style format string

  \( title1 \) arg = string
  
  string = text to print as 1st line of output file

  \( title2 \) arg = string
  
  string = text to print as 2nd line of output file

  \( title3 \) arg = string
  
  string = text to print as 3rd line of output file, only for vector mode

### 17.16.2 Examples

```bash
fix 1 all ave/time 100 5 1000 c_myTemp c_thermo_temp file temp.profile
fix 1 all ave/time 100 5 1000 c_thermo_press[2] ave window 20 &
    title1 "My output values"
fix 1 all ave/time 100 5 1000 c_thermo_press[*]
fix 1 all ave/time 1 100 1000 f_indent f_indent[1] file temp.indent off 1
```
17.16.3 Description

Use one or more global values as inputs every few timesteps, and average them over longer timescales. The resulting averages can be used by other output commands such as `thermo_style custom`, and can also be written to a file. Note that if no time averaging is done, this command can be used as a convenient way to simply output one or more global values to a file.

The group specified with this command is ignored. However, note that specified values may represent calculations performed by computes and fixes which store their own “group” definitions.

Each listed value can be the result of a `compute` or `fix` or the evaluation of an equal-style or vector-style `variable`. In each case, the compute, fix, or variable must produce a global quantity, not a per-atom or local quantity. If you wish to spatial- or time-average or histogram per-atom quantities from a compute, fix, or variable, then see the `fix ave/chunk`, `fix ave/atom`, or `fix ave/histo` commands. If you wish to sum a per-atom quantity into a single global quantity, see the `compute reduce` command.

Computes that produce global quantities are those which do not have the word `atom` in their style name. Only a few fixes produce global quantities. See the doc pages for individual fixes for info on which ones produce such values. Variables of style `equal` and `vector` are the only ones that can be used with this fix. Variables of style `atom` cannot be used, since they produce per-atom values.

The input values must either be all scalars or all vectors depending on the setting of the `mode` keyword. In both cases, the averaging is performed independently on each input value. i.e. each input scalar is averaged independently or each element of each input vector is averaged independently.

If `mode` = scalar, then the input values must be scalars, or vectors with a bracketed term appended, indicating the Ith value of the vector is used.

If `mode` = vector, then the input values must be vectors, or arrays with a bracketed term appended, indicating the Ith column of the array is used. All vectors must be the same length, which is the length of the vector or number of rows in the array.

For input values from a compute or fix or variable, the bracketed index I can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “*” or “*n” or “n*” or “m*n”. If N = the size of the vector (for `mode` = scalar) or the number of columns in the array (for `mode` = vector), then an asterisk with no numeric values means all indices from 1 to N. A leading asterisk means all indices from 1 to n (inclusive). A trailing asterisk means all indices from n to N (inclusive). A middle asterisk means all indices from m to n (inclusive).

Using a wildcard is the same as if the individual elements of the vector or columns of the array had been listed one by one. E.g. these 2 `fix ave/time` commands are equivalent, since the `compute rdf` command creates, in this case, a global array with 3 columns, each of length 50:

```plaintext
compute myRDF all rdf 50 1 2
fix 1 all ave/time 100 1 100 c_myRDF[*] file tmp1.rdf mode vector
```

Note: For a vector-style variable, only the wildcard forms “*n” or “m*n” are allowed. You must specify the upper bound, because vector-style variable lengths are not determined until the variable is evaluated. If n is specified larger than the vector length turns out to be, zeroes are output for missing vector values.

The `Nevery`, `Nrepeat`, and `Nfreq` arguments specify on what timesteps the input values will be used in order to contribute to the average. The final averaged quantities are generated on timesteps that are a multiple of `Nfreq`. The average is over `Nrepeat` quantities, computed in the preceding portion of the simulation every `Nevery` timesteps. `Nfreq` must be a
multiple of \textit{Nevery} and \textit{Nevery} must be non-zero even if \textit{Nrepeat} is 1. Also, the timesteps contributing to the average value cannot overlap, i.e. \textit{Nrepeat}\times\textit{Nevery} cannot exceed \textit{Nfreq}.

For example, if \textit{Nevery}=2, \textit{Nrepeat}=6, and \textit{Nfreq}=100, then values on timesteps 90,92,94,96,98,100 will be used to compute the final average on timestep 100. Similarly for timesteps 190,192,194,196,198,200 on timestep 200, etc. If \textit{Nrepeat}=1 and \textit{Nfreq}=100, then no time averaging is done; values are simply generated on timesteps 100,200, etc.

If a value begins with “c_”, a compute ID must follow which has been previously defined in the input script. If \textit{mode} = scalar, then if no bracketed term is appended, the global scalar calculated by the compute is used. If a bracketed term is appended, the Ith element of the global vector calculated by the compute is used. If \textit{mode} = vector, then if no bracketed term is appended, the global vector calculated by the compute is used. If a bracketed term is appended, the Ith column of the global array calculated by the compute is used. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

Note that there is a compute reduce command which can sum per-atom quantities into a global scalar or vector which can thus be accessed by fix ave/time. Or it can be a compute defined not in your input script, but by thermodynamic output or other fixes such as fix nvt or fix temp/rescale. See the doc pages for these commands which give the IDs of these computes. Users can also write code for their own compute styles and add them to LAMMPS.

If a value begins with “f_”, a fix ID must follow which has been previously defined in the input script. If \textit{mode} = scalar, then if no bracketed term is appended, the global scalar calculated by the fix is used. If a bracketed term is appended, the Ith element of the global vector calculated by the fix is used. If \textit{mode} = vector, then if no bracketed term is appended, the global vector calculated by the fix is used. If a bracketed term is appended, the Ith column of the global array calculated by the fix is used. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

Note that some fixes only produce their values on certain timesteps, which must be compatible with \textit{Nevery}, else an error will result. Users can also write code for their own fix styles and add them to LAMMPS.

If a value begins with “v_”, a variable name must follow which has been previously defined in the input script. If \textit{mode} = scalar, then only equal-style or vector-style variables can be used, which both produce global values. In this mode, a vector-style variable requires a bracketed term to specify the Ith element of the vector calculated by the variable. If \textit{mode} = vector, then only a vector-style variable can be used, without a bracketed term. See the variable command for details.

Note that variables of style \textit{equal} and \textit{vector} define a formula which can reference individual atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of specifying quantities to time average.

Additional optional keywords also affect the operation of this fix.

If the \textit{mode} keyword is set to \textit{scalar}, then all input values must be global scalars, or elements of global vectors. If the \textit{mode} keyword is set to \textit{vector}, then all input values must be global vectors, or columns of global arrays. They can also be global arrays, which are converted into a series of global vectors (one per column), as explained above.

The \textit{ave} keyword determines how the values produced every \textit{Nfreq} steps are averaged with values produced on previous steps that were multiples of \textit{Nfreq}, before they are accessed by another output command or written to a file.

If the \textit{ave} setting is \textit{one}, then the values produced on timesteps that are multiples of \textit{Nfreq} are independent of each other; they are output as-is without further averaging.

If the \textit{ave} setting is \textit{running}, then the values produced on timesteps that are multiples of \textit{Nfreq} are summed and averaged in a cumulative sense before being output. Each output value is thus the average of the value produced on that timestep with all preceding values. This running average begins when the fix is defined; it can only be restarted by deleting the fix via the \textit{unfix} command, or by re-defining the fix by re-specifying it.

If the \textit{ave} setting is \textit{window}, then the values produced on timesteps that are multiples of \textit{Nfreq} are summed and averaged within a moving “window” of time, so that the last M values are used to produce the output. E.g. if M = 3 and \textit{Nfreq}
= 1000, then the output on step 10000 will be the average of the individual values on steps 8000,9000,10000. Outputs on early steps will average over less than M values if they are not available.

The **start** keyword specifies what timestep averaging will begin on. The default is step 0. Often input values can be 0.0 at time 0, so setting **start** to a larger value can avoid including a 0.0 in a running or windowed average.

The **off** keyword can be used to flag any of the input values. If a value is flagged, it will not be time averaged. Instead the most recent input value will always be stored and output. This is useful if one of more of the inputs produced by a compute or fix or variable are effectively constant or are simply current values. E.g. they are being written to a file with other time-averaged values for purposes of creating well-formatted output.

The **file** keyword allows a filename to be specified. Every **Nfreq** steps, one quantity or vector of quantities is written to the file for each input value specified in the fix ave/time command. For **mode** = scalar, this means a single line is written each time output is performed. Thus the file ends up to be a series of lines, i.e. one column of numbers for each input value. For **mode** = vector, an array of numbers is written each time output is performed. The number of rows is the length of the input vectors, and the number of columns is the number of values. Thus the file ends up to be a series of these array sections.

If the filename ends in ‘.yaml’ or ‘.yml’ then the output format conforms to the **YAML** standard which allows easy import that data into tools and scripts that support reading YAML files. The **structured data Howto** contains examples for parsing and plotting such data with very little programming effort in Python using the **pyyaml**, **pandas**, and **matplotlib** packages.

The **overwrite** keyword will continuously overwrite the output file with the latest output, so that it only contains one timestep worth of output. This option can only be used with the **ave running** setting.

The **format** keyword sets the numeric format of each value when it is printed to a file via the **file** keyword. Note that all values are floating point quantities. The default format is %g. You can specify a higher precision if desired, e.g. %20.16g.

The **title1** and **title2** and **title3** keywords allow specification of the strings that will be printed as the first 2 or 3 lines of the output file, assuming the **file** keyword was used. LAMMPS uses default values for each of these, so they do not need to be specified.

By default, these header lines are as follows for **mode** = scalar:

```plaintext
# Time-averaged data for fix ID
# TimeStep value1 value2 ...
```

In the first line, ID is replaced with the fix-ID. In the second line the values are replaced with the appropriate fields from the fix ave/time command. There is no third line in the header of the file, so the **title3** setting is ignored when **mode** = scalar.

By default, these header lines are as follows for **mode** = vector:

```plaintext
# Time-averaged data for fix ID
# TimeStep Number-of-rows
# Row value1 value2 ...
```

In the first line, ID is replaced with the fix-ID. The second line describes the two values that are printed at the first of each section of output. In the third line the values are replaced with the appropriate fields from the fix ave/time command.
17.16.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. The fix_modify colname option can be used to change the name of the column in the output file. When writing a YAML format file this name will be in the list of keywords.

This fix produces a global scalar or global vector or global array which can be accessed by various output commands. The values can only be accessed on timesteps that are multiples of Nfreq since that is when averaging is performed.

A scalar is produced if only a single input value is averaged and mode = scalar. A vector is produced if multiple input values are averaged for mode = scalar, or a single input value for mode = vector. In the first case, the length of the vector is the number of inputs. In the second case, the length of the vector is the same as the length of the input vector. An array is produced if multiple input values are averaged and mode = vector. The global array has # of rows = length of the input vectors and # of columns = number of inputs.

If the fix produces a scalar or vector, then the scalar and each element of the vector can be either “intensive” or “extensive”, depending on whether the values contributing to the scalar or vector element are “intensive” or “extensive”. If the fix produces an array, then all elements in the array must be the same, either “intensive” or “extensive”. If a compute or fix provides the value being time averaged, then the compute or fix determines whether the value is intensive or extensive; see the page for that compute or fix for further info. Values produced by a variable are treated as intensive.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.16.5 Restrictions

none

17.16.6 Related commands

compute, fix ave/atom, fix ave/chunk, fix ave/histo, variable, fix ave/correlate,

17.16.7 Default

The option defaults are mode = scalar, ave = one, start = 0, no file output, format = %g, title 1,2,3 = strings as described above, and no off settings for any input values.

17.17 fix aveforce command

17.17.1 Syntax

| fix ID group-ID aveforce fx fy fz keyword value ... |

- ID, group-ID are documented in fix command
- aveforce = style name of this fix command
- fx,fy,fz = force component values (force units)
  - any of fx,fy,fz can be a variable (see below)
- zero or more keyword/value pairs may be appended to args
- keyword = region
region value = region-ID
region-ID = ID of region atoms must be in to have added force

17.17.2 Examples

```
fix pressdown topwall aveforce 0.0 -1.0 0.0
fix 2 bottomwall aveforce NULL -1.0 0.0 region top
fix 2 bottomwall aveforce NULL -1.0 v_oscillate region top
```

17.17.3 Description

Apply an additional external force to a group of atoms in such a way that every atom experiences the same force. This is useful for pushing on wall or boundary atoms so that the structure of the wall does not change over time.

The existing force is averaged for the group of atoms, component by component. The actual force on each atom is then set to the average value plus the component specified in this command. This means each atom in the group receives the same force.

Any of the fx, fy, fz values can be specified as NULL which means the force in that dimension is not changed. Note that this is not the same as specifying a 0.0 value, since that sets all forces to the same average value without adding in any additional force.

Any of the 3 quantities defining the force components can be specified as an equal-style variable, namely fx, fy, fz. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the average force.

Equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent average force.

If the region keyword is used, the atom must also be in the specified geometric region in order to have force added to it.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
17.17.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify respa option is supported by this fix. This allows to set at which level of the rRESPA integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global 3-vector of forces, which can be accessed by various output commands. This is the total force on the group of atoms before the forces on individual atoms are changed by the fix. The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command. You should not specify force components with a variable that has time-dependence for use with a minimizer, since the minimizer increments the timestep as the iteration count during the minimization.

fix 2 all balance 100 0.9 shift xy 20 1.1 out tmp.balance
fix 2 all balance 100 0.9 shift xy 20 1.1 weight group 3 substrate 3.0 solvent 1.0
  ...solve 0.8 out tmp.balance
fix 2 all balance 100 1.0 shift x 10 1.1 weight time 0.8
fix 2 all balance 100 1.0 shift xy 5 1.1 weight var myweight weight neigh 0.6 weight...
  ...store allweight
fix 2 all balance 1000 1.1 rcb
```

17.18.3 Description

This command adjusts the size and shape of processor sub-domains within the simulation box, to attempt to balance the number of particles and thus the computational cost (load) evenly across processors. The load balancing is “dynamic” in the sense that re-balancing is performed periodically during the simulation. To perform “static” balancing, before or between runs, see the balance command.

Load-balancing is typically most useful if the particles in the simulation box have a spatially-varying density distribution or where the computational cost varies significantly between different atoms. E.g. a model of a vapor/liquid interface, or a solid with an irregular-shaped geometry containing void regions, or hybrid pair style simulations which combine pair styles with different computational cost. In these cases, the LAMMPS default of dividing the simulation box volume into a regular-spaced grid of 3d bricks, with one equal-volume sub-domain per processor, may assign numbers of particles per processor in a way that the computational effort varies significantly. This can lead to poor performance when the simulation is run in parallel.

The balancing can be performed with or without per-particle weighting. With no weighting, the balancing attempts to assign an equal number of particles to each processor. With weighting, the balancing attempts to assign an equal aggregate computational weight to each processor, which typically induces a different number of atoms assigned to each processor.

Note: The weighting options listed above are documented with the balance command in this section of the balance command doc page. That section describes the various weighting options and gives a few examples of how they can
be used. The weighting options are the same for both the fix balance and balance commands.

Note that the **processors** command allows some control over how the box volume is split across processors. Specifically, for a Px by Py by Pz grid of processors, it allows choice of Px, Py, and Pz, subject to the constraint that Px * Py * Pz = P, the total number of processors. This is sufficient to achieve good load-balance for some problems on some processor counts. However, all the processor sub-domains will still have the same shape and same volume.

On a particular timestep, a load-balancing operation is only performed if the current “imbalance factor” in particles owned by each processor exceeds the specified **thresh** parameter. The imbalance factor is defined as the maximum number of particles (or weight) owned by any processor, divided by the average number of particles (or weight) per processor. Thus an imbalance factor of 1.0 is perfect balance.

As an example, for 10000 particles running on 10 processors, if the most heavily loaded processor has 1200 particles, then the factor is 1.2, meaning there is a 20% imbalance. Note that re-balances can be forced even if the current balance is perfect (1.0) by specifying a **thresh < 1.0**.

**Note:** This command attempts to minimize the imbalance factor, as defined above. But depending on the method a perfect balance (1.0) may not be achieved. For example, “grid” methods (defined below) that create a logical 3d grid cannot achieve perfect balance for many irregular distributions of particles. Likewise, if a portion of the system is a perfect lattice, e.g. the initial system is generated by the create_atoms command, then “grid” methods may be unable to achieve exact balance. This is because entire lattice planes will be owned or not owned by a single processor.

**Note:** The imbalance factor is also an estimate of the maximum speed-up you can hope to achieve by running a perfectly balanced simulation versus an imbalanced one. In the example above, the 10000 particle simulation could run up to 20% faster if it were perfectly balanced, versus when imbalanced. However, computational cost is not strictly proportional to particle count, and changing the relative size and shape of processor sub-domains may lead to additional computational and communication overheads, e.g. in the PPPM solver used via the kspace_style command. Thus you should benchmark the run times of a simulation before and after balancing.

The method used to perform a load balance is specified by one of the listed styles, which are described in detail below. There are 2 kinds of styles.

The **shift** style is a “grid” method which produces a logical 3d grid of processors. It operates by changing the cutting planes (or lines) between processors in 3d (or 2d), to adjust the volume (area in 2d) assigned to each processor, as in the following 2d diagram where processor sub-domains are shown and atoms are colored by the processor that owns them.

The leftmost diagram is the default partitioning of the simulation box across processors (one sub-box for each of 16 processors); the middle diagram is after a “grid” method has been applied. The **rcb** style is a “tiling” method which
does not produce a logical 3d grid of processors. Rather it tiles the simulation domain with rectangular sub-boxes of varying size and shape in an irregular fashion so as to have equal numbers of particles (or weight) in each sub-box, as in the rightmost diagram above.

The “grid” methods can be used with either of the `comm_style` command options, `brick` or `tiled`. The “tiling” methods can only be used with `comm_style tiled`.

When a “grid” method is specified, the current domain partitioning can be either a logical 3d grid or a tiled partitioning. In the former case, the current logical 3d grid is used as a starting point and changes are made to improve the imbalance factor. In the latter case, the tiled partitioning is discarded and a logical 3d grid is created with uniform spacing in all dimensions. This is the starting point for the balancing operation.

When a “tiling” method is specified, the current domain partitioning (“grid” or “tiled”) is ignored, and a new partitioning is computed from scratch.

The `group-ID` is ignored. However the impact of balancing on different groups of atoms can be affected by using the `group` weight style as described below.

The `Nfreq` setting determines how often a re-balance is performed. If `Nfreq > 0`, then re-balancing will occur every `Nfreq` steps. Each time a re-balance occurs, a reneighboring is triggered, so `Nfreq` should not be too small. If `Nfreq = 0`, then re-balancing will be done every time reneighboring normally occurs, as determined by the the `neighbor` and `neigh_modify` command settings.

On re-balance steps, re-balancing will only be attempted if the current imbalance factor, as defined above, exceeds the `thresh` setting.

The `shift` style invokes a “grid” method for balancing, as described above. It changes the positions of cutting planes between processors in an iterative fashion, seeking to reduce the imbalance factor.

The `dimstr` argument is a string of characters, each of which must be an “x” or “y” or “z”. Each character can appear zero or one time, since there is no advantage to balancing on a dimension more than once. You should normally only list dimensions where you expect there to be a density variation in the particles.

Balancing proceeds by adjusting the cutting planes in each of the dimensions listed in `dimstr`, one dimension at a time. For a single dimension, the balancing operation (described below) is iterated on up to `Niter` times. After each dimension finishes, the imbalance factor is re-computed, and the balancing operation halts if the `stopthresh` criterion is met.

A re-balance operation in a single dimension is performed using a density-dependent recursive multisecting algorithm, where the position of each cutting plane (line in 2d) in the dimension is adjusted independently. This is similar to a recursive bisectioning for a single value, except that the bounds used for each bisectioning take advantage of information from neighboring cuts if possible, as well as counts of particles at the bounds on either side of each cuts, which themselves were cuts in previous iterations. The latter is used to infer a density of particles near each of the current cuts. At each iteration, the count of particles on either side of each plane is tallied. If the counts do not match the target value for the plane, the position of the cut is adjusted based on the local density. The low and high bounds are adjusted on each iteration, using new count information, so that they become closer together over time. Thus as the recursion progresses, the count of particles on either side of the plane gets closer to the target value.

The density-dependent part of this algorithm is often an advantage when you re-balance a system that is already nearly balanced. It typically converges more quickly than the geometric bisectioning algorithm used by the `balance` command. However, if can be a disadvantage if you attempt to re-balance a system that is far from balanced, and converge more slowly. In this case you probably want to use the `balance` command before starting a run, so that you begin the run with a balanced system.

Once the re-balancing is complete and final processor sub-domains assigned, particles migrate to their new owning processor as part of the normal reneighboring procedure.
Note: At each re-balance operation, the bisectioning for each cutting plane (line in 2d) typically starts with low and high bounds separated by the extent of a processor’s sub-domain in one dimension. The size of this bracketing region shrinks based on the local density, as described above, which should typically be 1/2 or more every iteration. Thus if \( N_{\text{iter}} \) is specified as 10, the cutting plane will typically be positioned to better than 1 part in 1000 accuracy (relative to the perfect target position). For \( N_{\text{iter}} = 20 \), it will be accurate to better than 1 part in a million. Thus there is no need to set \( N_{\text{iter}} \) to a large value. This is especially true if you are re-balancing often enough that each time you expect only an incremental adjustment in the cutting planes is necessary. LAMMPS will check if the threshold accuracy is reached (in a dimension) is less iterations than \( N_{\text{iter}} \) and exit early.

The \textit{rcb} style invokes a “tiled” method for balancing, as described above. It performs a recursive coordinate bisectioning (RCB) of the simulation domain. The basic idea is as follows.

The simulation domain is cut into 2 boxes by an axis-aligned cut in the longest dimension, leaving one new box on either side of the cut. All the processors are also partitioned into 2 groups, half assigned to the box on the lower side of the cut, and half to the box on the upper side. (If the processor count is odd, one side gets an extra processor.) The cut is positioned so that the number of atoms in the lower box is exactly the number that the processors assigned to that box should own for load balance to be perfect. This also makes load balance for the upper box perfect. The positioning is done iteratively, by a bisectioning method. Note that counting atoms on either side of the cut requires communication between all processors at each iteration.

That is the procedure for the first cut. Subsequent cuts are made recursively, in exactly the same manner. The subset of processors assigned to each box make a new cut in the longest dimension of that box, splitting the box, the subset of processors, and the atoms in the box into two. The recursion continues until every processor is assigned a sub-box of the entire simulation domain, and owns the atoms in that sub-box.

The \textit{out} keyword writes text to the specified \textit{filename} with the results of each re-balancing operation. The file contains the bounds of the sub-domain for each processor after the balancing operation completes. The format of the file is compatible with the Pizza.py \textit{mdump} tool which has support for manipulating and visualizing mesh files. An example is shown here for a balancing by 4 processors for a 2d problem:

```
ITEM: TIMESTEP
  0
ITEM: NUMBER OF NODES
  16
ITEM: BOX BOUNDS
  0  10
  0  10
  0  10
ITEM: NODES
  1  1  0  0  0
  2  1  5  0  0
  3  1  5  5  0
  4  1  0  5  0
  5  1  5  0  0
  6  1  1  0  0
  7  1  1  5  0
  8  1  5  5  0
  9  1  0  5  0
 10  1  5  5  0
 11  1  5  1  0
```
The coordinates of all the vertices are listed in the NODES section, 5 per processor. Note that the 4 sub-domains share vertices, so there will be duplicate nodes in the list.

The “SQUARES” section lists the node IDs of the 4 vertices in a rectangle for each processor (1 to 4).

For a 3d problem, the syntax is similar with 8 vertices listed for each processor, instead of 4, and “SQUARES” replaced by “CUBES”.

### 17.18.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix.

This fix computes a global scalar which is the imbalance factor after the most recent re-balance and a global vector of length 3 with additional information about the most recent re-balancing. The 3 values in the vector are as follows:

- **1** = max # of particles per processor
- **2** = total # iterations performed in last re-balance
- **3** = imbalance factor right before the last re-balance was performed

As explained above, the imbalance factor is the ratio of the maximum number of particles (or total weight) on any processor to the average number of particles (or total weight) per processor.

These quantities can be accessed by various output commands. The scalar and vector values calculated by this fix are “intensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.
17.18.5 Restrictions

For 2d simulations, the z style cannot be used. Nor can a “z” appear in dimstr for the shift style. Balancing through recursive bisectioning (rcb style) requires comm_style tiled.

17.19 fix bocs command

17.19.1 Syntax

fix  ID group-ID bocs keyword values ...

keyword = temp or cgiso or analytic or linear_spline or cubic_spline

  temp values = Tstart Tstop Tdamp
  cgiso values = Pstart Pstop Pdamp
  basis set
    analytic values = V_avg N_particles N_coeff Coeff_1 Coeff_2 ... Coeff_N
    linear_spline values = input_filename
    cubic_spline values = input_filename

17.19.2 Examples

```plaintext
fix 1 all bocs temp 300.0 300.0 100.0 cgiso 0.986 0.986 1000.0 analytic 66476.015 968 2 245030.10 8962.20
fix 1 all bocs temp 300.0 300.0 100.0 cgiso 0.986 0.986 1000.0 cubic_spline input_Fv.dat
thermo_modify press 1_press
```

17.19.3 Description

These commands incorporate a pressure correction as described by Dunn and Noid in (Dunn1) to the standard MTTK barostat by Martyna et. al. in (Martyna). The first half of the command mimics a standard fix npt command:

```plaintext
fix 1 all bocs temp Tstart Tstop Tcoup1 cgiso Pstart Pstop Pdamp
```

The two differences are replacing npt with bocs, and replacing isolanisolec with cgiso. The rest of the command details what form you would like to use for the pressure correction equation. The choices are: analytic, linear_spline, or cubic_spline.
With either spline method, the only argument that needs to follow it is the name of a file that contains the desired pressure correction as a function of volume. The file must be formatted so each line has:

| Volume_i, PressureCorrection_i |

Note both the COMMA and the SPACE separating the volume's value and its corresponding pressure correction. The volumes in the file must be uniformly spaced. Both the volumes and the pressure corrections should be provided in the proper units, e.g. if you are using \textit{units real}, the volumes should all be in cubic angstroms, and the pressure corrections should all be in atmospheres. Furthermore, the table should start/end at a volume considerably smaller/larger than you expect your system to sample during the simulation. If the system ever reaches a volume outside of the range provided, the simulation will stop.

With the \textit{analytic} option, the arguments are as follows:

\begin{verbatim}
... analytic V_avg N_particles N_coeff Coeff_1 Coeff_2 ... Coeff_N
\end{verbatim}

Note that \textit{V_avg} and \textit{Coeff_i} should all be in the proper units, e.g. if you are using \textit{units real}, \textit{V_avg} should be in cubic angstroms, and the coefficients should all be in atmospheres * cubic angstroms.

### 17.19.4 Restart, fix\_modify, output, run start/stop, minimize info

This fix writes the cumulative global energy change to \textit{binary restart files}. See the \textit{read_restart} command for info on how to re-specify a fix in an input script that reads a restart file, so that the fix continues in an uninterrupted fashion.

The \textit{fix\_modify temp} option is supported by this fix. You can use it to assign a temperature \textit{compute} you have defined to this fix which will be used in its thermostatting procedure, as described above. For consistency, the group used by this fix and by the compute should be the same.

The cumulative energy change in the system imposed by this fix is included in the \textit{thermodynamic output} keywords \textit{ecouple} and \textit{econserve}. See the \textit{thermo_style} doc page for details.

This fix computes a global scalar which can be accessed by various \textit{output commands}. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

This fix can ramp its target temperature over multiple runs, using the \textit{start} and \textit{stop} keywords of the \textit{run} command. See the \textit{run} command for details of how to do this.

This fix is not invoked during \textit{energy minimization}.

### 17.19.5 Restrictions

As this is computing a (modified) pressure, group-ID should be \textit{all}.

The pressure correction has only been tested for use with an isotropic pressure coupling in 3 dimensions.

By default, LAMMPS will still report the normal value for the pressure if the pressure is printed via a \textit{thermo} command, or if the pressures are written to a file every so often. In order to have LAMMPS report the modified pressure, you must include the \textit{thermo\_modify} command given in the examples. For the last argument in the command, you should put \texttt{XXXX\_press}, where \texttt{XXXX} is the ID given to the fix bocs command (in the example, the ID of the fix bocs command is 1).

This fix is part of the BOCS package. It is only enabled if LAMMPS was built with that package. See the \textit{Build package} page for more info.
17.19.6 Further information

For more details about the pressure correction and the entire BOCS software package, visit the BOCS package on GitHub and read the release paper by Dunn et. al. (Dunn2).

17.20 fix bond/break command

17.20.1 Syntax

fix ID group-ID bond/break Nevery bondtype Rmax keyword values ...  

- ID, group-ID are documented in fix command  
- bond/break = style name of this fix command  
- Nevery = attempt bond breaking every this many steps  
- bondtype = type of bonds to break  
- Rmax = bond longer than Rmax can break (distance units)  
- zero or more keyword/value pairs may be appended to args  
- keyword = prob  
  prob values = fraction seed  
  fraction = break a bond with this probability if otherwise eligible  
  seed = random number seed (positive integer)

17.20.2 Examples

```plaintext
fix 5 all bond/break 10 2 1.2
fix 5 polymer bond/break 1 1 2.0 prob 0.5 49829
```

17.20.3 Description

Break bonds between pairs of atoms as a simulation runs according to specified criteria. This can be used to model the dissolution of a polymer network due to stretching of the simulation box or other deformations. In this context, a bond means an interaction between a pair of atoms computed by the bond_style command. Once the bond is broken it will be permanently deleted, as will all angle, dihedral, and improper interactions that bond is part of.

This is different than a pairwise bond-order potential such as Tersoff or AIREBO which infers bonds and many-body interactions based on the current geometry of a small cluster of atoms and effectively creates and destroys bonds and higher-order many-body interactions from timestep to timestep as atoms move.

A check for possible bond breakage is performed every Nevery timesteps. If two bonded atoms I,J are further than a distance Rmax of each other, if the bond is of type bondtype, and if both I and J are in the specified fix group, then I,J is labeled as a “possible” bond to break.
If several bonds involving an atom are stretched, it may have multiple possible bonds to break. Every atom checks its list of possible bonds to break and labels the longest such bond as its “sole” bond to break. After this is done, if atom I is bonded to atom J in its sole bond, and atom J is bonded to atom I in its sole bond, then the IJ bond is “eligible” to be broken.

Note that these rules mean an atom will only be part of at most one broken bond on a given timestep. It also means that if atom I chooses atom J as its sole partner, but atom J chooses atom K as its sole partner (due to $R_{jk} > R_{ij}$), then this means atom I will not be part of a broken bond on this timestep, even if it has other possible bond partners.

The `prob` keyword can effect whether an eligible bond is actually broken. The `fraction` setting must be a value between 0.0 and 1.0. A uniform random number between 0.0 and 1.0 is generated and the eligible bond is only broken if the random number < fraction.

When a bond is broken, data structures within LAMMPS that store bond topology are updated to reflect the breakage. Likewise, if the bond is part of a 3-body (angle) or 4-body (dihedral, improper) interaction, that interaction is removed as well. These changes typically affect pairwise interactions between atoms that used to be part of bonds, angles, etc.

---

Note: One data structure that is not updated when a bond breaks are the molecule IDs stored by each atom. Even though one molecule becomes two molecules due to the broken bond, all atoms in both new molecules retain their original molecule IDs.

Computationally, each timestep this fix operates, it loops over all the bonds in the system and computes distances between pairs of bonded atoms. It also communicates between neighboring processors to coordinate which bonds are broken. Moreover, if any bonds are broken, neighbor lists must be immediately updated on the same timestep. This is to insure that any pairwise interactions that should be turned “on” due to a bond breaking, because they are no longer excluded by the presence of the bond and the settings of the `special_bonds` command, will be immediately recognized. All of these operations increase the cost of a timestep. Thus you should be cautious about invoking this fix too frequently.

You can dump out snapshots of the current bond topology via the `dump local` command.

---

Note: Breaking a bond typically alters the energy of a system. You should be careful not to choose bond breaking criteria that induce a dramatic change in energy. For example, if you define a very stiff harmonic bond and break it when 2 atoms are separated by a distance far from the equilibrium bond length, then the 2 atoms will be dramatically released when the bond is broken. More generally, you may need to thermostat your system to compensate for energy changes resulting from broken bonds (and angles, dihedrals, impropers).

See the Howto page on broken bonds for more information on related features in LAMMPS.

---

### 17.20.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix.

This fix computes two statistics which it stores in a global vector of length 2, which can be accessed by various output commands. The vector values calculated by this fix are “intensive”.

These are the 2 quantities:

- (1) # of bonds broken on the most recent breakage timestep
- (2) cumulative # of bonds broken

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.
17.20.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

17.20.6 Related commands

fix bond/create, fix bond/react, fix bond/swap, dump local, special_bonds

17.20.7 Default

The option defaults are prob = 1.0.

17.21 fix bond/create command

17.22.1 Syntax

```
fix ID group-ID bond/create Nevery itype jtype Rmin bondtype keyword values ...
```

- ID, group-ID are documented in fix command
- bond/create = style name of this fix command
- Nevery = attempt bond creation every this many steps
- itype,jtype = atoms of itype can bond to atoms of jtype
- Rmin = 2 atoms separated by less than Rmin can bond (distance units)
- bondtype = type of created bonds
- zero or more keyword/value pairs may be appended to args
- keyword = iparam or jparam or prob or atype or dtype or itype or aconstrain
  - iparam values = maxbond, newtype
    - maxbond = max # of bonds of bondtype the itype atom can have
    - newtype = change the itype atom to this type when maxbonds exist
  - jparam values = maxbond, newtype
    - maxbond = max # of bonds of bondtype the jtype atom can have
    - newtype = change the jtype atom to this type when maxbonds exist
  - prob values = fraction seed
    - fraction = create a bond with this probability if otherwise eligible
    - seed = random number seed (positive integer)
  - atype value = angletype
    - angletype = type of created angles
  - dtype value = dihedraltype
    - dihedraltype = type of created dihedrals
  - itype value = impropertype
    - impropertype = type of created impropers
  - aconstrain value = amin amax
```
amin = minimal angle at which new bonds can be created
amax = maximal angle at which new bonds can be created

```

17.22.3 Description

Create bonds between pairs of atoms as a simulation runs according to specified criteria. This can be used to model cross-linking of polymers, the formation of a percolation network, etc. In this context, a bond means an interaction between a pair of atoms computed by the `bond_style` command. Once the bond is created it will be permanently in place. Optionally, the creation of a bond can also create angle, dihedral, and improper interactions that bond is part of. See the discussion of the `atype`, `dtype`, and `itype` keywords below.

This is different than a pairwise bond-order potential such as Tersoff or AIREBO which infers bonds and many-body interactions based on the current geometry of a small cluster of atoms and effectively creates and destroys bonds and higher-order many-body interactions from timestep to timestep as atoms move.

A check for possible new bonds is performed every `Nevery` timesteps. If two atoms IJ are within a distance `Rmin` of each other, if I is of atom type `itype`, if J is of atom type `jtype`, if both I and J are in the specified fix group, if a bond does not already exist between I and J, and if both I and J meet their respective `maxbond` requirement (explained below), then I,J is labeled as a “possible” bond pair.

If several atoms are close to an atom, it may have multiple possible bond partners. Every atom checks its list of possible bond partners and labels the closest such partner as its “sole” bond partner. After this is done, if atom I has atom J as its sole partner, and atom J has atom I as its sole partner, then the I,J bond is “eligible” to be formed.

Note that these rules mean an atom will only be part of at most one created bond on a given timestep. It also means that if atom I chooses atom J as its sole partner, but atom J chooses atom K as its sole partner (due to `Rjk < Rij`), then this means atom I will not form a bond on this timestep, even if it has other possible bond partners.

It is permissible to have `itype = jtype`. `Rmin` must be <= the pairwise cutoff distance between `itype` and `jtype` atoms, as defined by the `pair_style` command.

The `iparam` and `jparam` keywords can be used to limit the bonding functionality of the participating atoms. Each atom keeps track of how many bonds of `bondtype` it already has. If atom I of `itype` already has `maxbond` bonds (as set by the `iparam` keyword), then it will not form any more. Likewise for atom J. If `maxbond` is set to 0, then there is no limit on the number of bonds that can be formed with that atom.

The `newtype` value for `iparam` and `jparam` can be used to change the atom type of atom I or J when it reaches `maxbond` number of bonds of type `bondtype`. This means it can now interact in a pairwise fashion with other atoms in a different way by specifying different `pair_coeff` coefficients. If you do not wish the atom type to change, simply specify `newtype` as `itype` or `jtype`.

The `prob` keyword can also effect whether an eligible bond is actually created. The `fraction` setting must be a value between 0.0 and 1.0. A uniform random number between 0.0 and 1.0 is generated and the eligible bond is only created if the random number < fraction.

The `aconstrain` keyword is only available with the fix bond/create/angle command. It allows to specify a minimal and maximal angle `amin` and `amax` between the two prospective bonding partners and a third particle that is already bonded to one of the two partners. Such a criterion can be important when new angles are defined together with the formation
of a new bond. Without a restriction on the permissible angle, and for stiffer angle potentials, very large energies can arise and lead to uncontrolled behavior.

Any bond that is created is assigned a bond type of bondtype. When a bond is created, data structures within LAMMPS that store bond topology are updated to reflect the creation. If the bond is part of new 3-body (angle) or 4-body (dihedral, improper) interactions, you can choose to create new angles, dihedrals, impropers as well, using the atype, dtype, and itype keywords. All of these changes typically affect pairwise interactions between atoms that are now part of new bonds, angles, etc.

**Note:** One data structure that is not updated when a bond breaks are the molecule IDs stored by each atom. Even though two molecules become one molecule due to the created bond, all atoms in the new molecule retain their original molecule IDs.

If the atype keyword is used and if an angle potential is defined via the angle_style command, then any new 3-body interactions inferred by the creation of a bond will create new angles of type angletype, with parameters assigned by the corresponding angle_coeff command. Likewise, the dtype and itype keywords will create new dihedrals and impropers of type dihedraltype and impropertype.

**Note:** To create a new bond, the internal LAMMPS data structures that store this information must have space for it. When LAMMPS is initialized from a data file, the list of bonds is scanned and the maximum number of bonds per atom is tallied. If some atom will acquire more bonds than this limit as this fix operates, then the “extra bond per atom” parameter must be set to allow for it. Ditto for “extra angle per atom”, “extra dihedral per atom”, and “extra improper per atom” if angles, dihedrals, or impropers are being added when bonds are created. See the read_data or create_box command for more details. Note that a data file with no atoms can be used if you wish to add non-bonded atoms via the create atoms command, e.g. for a percolation simulation.

**Note:** LAMMPS stores and maintains a data structure with a list of the first, second, and third neighbors of each atom (within the bond topology of the system) for use in weighting pairwise interactions for bonded atoms. Note that adding a single bond always adds a new first neighbor but may also induce *many* new second and third neighbors, depending on the molecular topology of your system. The “extra special per atom” parameter must typically be set to allow for the new maximum total size (first + second + third neighbors) of this per-atom list. There are 2 ways to do this. See the read_data or create_box commands for details.

**Note:** Even if you do not use the atype, dtype, or itype keywords, the list of topological neighbors is updated for atoms affected by the new bond. This in turn affects which neighbors are considered for pairwise interactions, using the weighting rules set by the special_bonds command. Consider a new bond created between atoms I,J. If J has a bonded neighbor K, then K becomes a second neighbor of I. Even if the atype keyword is not used to create angle I-J-K, the pairwise interaction between I and K will be potentially turned off or weighted by the 1-3 weighting specified by the special_bonds command. This is the case even if the “angle yes” option was used with that command. The same is true for third neighbors (1-4 interactions), the dtype keyword, and the “dihedral yes” option used with the special_bonds command.

Note that even if your simulation starts with no bonds, you must define a bond_style and use the bond_coeff command to specify coefficients for the bondtype. Similarly, if new atom types are specified by the iparam or jparam keywords, they must be within the range of atom types allowed by the simulation and pairwise coefficients must be specified for the new types.

Computationally, each timestep this fix operates, it loops over neighbor lists and computes distances between pairs of atoms in the list. It also communicates between neighboring processors to coordinate which bonds are created.
Moreover, if any bonds are created, neighbor lists must be immediately updated on the same timestep. This is to insure that any pairwise interactions that should be turned “off” due to a bond creation, because they are now excluded by the presence of the bond and the settings of the `special_bonds` command, will be immediately recognized. All of these operations increase the cost of a timestep. Thus you should be cautious about invoking this fix too frequently.

You can dump out snapshots of the current bond topology via the `dump local` command.

**Note:** Creating a bond typically alters the energy of a system. You should be careful not to choose bond creation criteria that induce a dramatic change in energy. For example, if you define a very stiff harmonic bond and create it when 2 atoms are separated by a distance far from the equilibrium bond length, then the 2 atoms will oscillate dramatically when the bond is formed. More generally, you may need to thermostat your system to compensate for energy changes resulting from created bonds (and angles, dihedrals, impropers).

### 17.22.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the `fix_modify` options are relevant to this fix.

This fix computes two statistics which it stores in a global vector of length 2, which can be accessed by various `output commands`. The vector values calculated by this fix are “intensive”.

These are the 2 quantities:

- (1) # of bonds created on the most recent creation timestep
- (2) cumulative # of bonds created

No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during energy minimization.

### 17.22.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the `Build package` doc page for more info.

### 17.22.6 Related commands

`fix bond/break, fix bond/react, fix bond/swap, dump local, special_bonds`

17.23 fix bond/react command

17.23.1 Syntax

```
fix ID group-ID bond/react common_keyword values ...  
   react react-ID react-group-ID Nevery Rmin Rmax template-ID(pre-reacted) template-ID(post-reacted) map_file individual_keyword values ...  
```

- ID, group-ID are documented in `fix` command.
- bond/react = style name of this fix command
- the common keyword/values may be appended directly after ‘bond/react’
- common keywords apply to all reaction specifications
- common_keyword = stabilization or reset_mol_ids
  - stabilization values = no or yes group-ID xmax
    - no = no reaction site stabilization (default)
    - yes = perform reaction site stabilization
      - group-ID = user-assigned prefix for the dynamic group of atoms not currently involved in a reaction
    - xmax = xmax value that is used by an internally-created nve/limit integrator
  - reset_mol_ids values = yes or no
    - yes = update molecule IDs based on new global topology (default)
    - no = do not update molecule IDs
- react = mandatory argument indicating new reaction specification
- react-ID = user-assigned name for the reaction
- react-group-ID = only atoms in this group are considered for the reaction
- Nevery = attempt reaction every this many steps
- Rmin = initiator atoms must be separated by more than Rmin to initiate reaction (distance units)
- Rmax = initiator atoms must be separated by less than Rmax to initiate reaction (distance units)
- template-ID(pre-reacted) = ID of a molecule template containing pre-reaction topology
- template-ID(post-reacted) = ID of a molecule template containing post-reaction topology
- map_file = name of file specifying corresponding atom-IDs in the pre- and post-reacted templates
- zero or more individual keyword/value pairs may be appended to each react argument
- individual_keyword = prob or max_rxn or stabilize_steps or custom_charges or molecule or modify_create
  - prob values = fraction seed
    - fraction = initiate reaction with this probability if otherwise eligible
    - seed = random number seed (positive integer)
  - max_rxn value = N
    - N = maximum number of reactions allowed to occur
  - stabilize_steps value = timesteps
timesteps = number of timesteps to apply the internally-created nve/limit fix to reacting atoms
custom_charges value = no or fragmentID
  no = update all atomic charges (default)
  fragmentID = ID of molecule fragment whose charges are updated
molecule value = off or inter or intra
  off = allow both inter- and intramolecular reactions (default)
  inter = search for reactions between molecules with different IDs
  intra = search for reactions within the same molecule
modify_create keyword values
  fit value = all or fragmentID
    all = use all eligible atoms for create-atoms fit (default)
    fragmentID = ID of molecule fragment used for create-atoms fit
  overlap value = R
    R = only insert atom/molecule if further than R from existing particles

17.23.2 Examples

```

17.23.3 Description

Initiate complex covalent bonding (topology) changes. These topology changes will be referred to as ‘reactions’ throughout this documentation. Topology changes are defined in pre- and post-reaction molecule templates and can include creation and deletion of bonds, angles, dihedrals, improper, bond types, angle types, dihedral types, atom types, or atomic charges. In addition, reaction by-products or other molecules can be identified and deleted. Finally, atoms can be created and inserted at specific positions relative to the reaction site.

Fix bond/react does not use quantum mechanical (e.g. fix qmmm) or pairwise bond-order potential (e.g. Tersoff or AIREBO) methods to determine bonding changes a priori. Rather, it uses a distance-based probabilistic criteria to effect predetermined topology changes in simulations using standard force fields.

This fix was created to facilitate the dynamic creation of polymeric, amorphous or highly cross-linked systems. A suggested workflow for using this fix is: 1) identify a reaction to be simulated 2) build a molecule template of the reaction site before the reaction has occurred 3) build a molecule template of the reaction site after the reaction has occurred 4) create a map that relates the template-atom-IDs of each atom between pre- and post-reaction molecule templates 5) fill a simulation box with molecules and run a simulation with fix bond/react.
Only one ‘fix bond/react’ command can be used at a time. Multiple reactions can be simultaneously applied by specifying multiple react arguments to a single ‘fix bond/react’ command. This syntax is necessary because the ‘common keywords’ are applied to all reactions.

The stabilization keyword enables reaction site stabilization. Reaction site stabilization is performed by including reacting atoms in an internally-created fix nve/limit time integrator for a set number of timesteps given by the stabilize_steps keyword. While reacting atoms are being time integrated by the internal nve/limit, they are prevented from being involved in any new reactions. The xmax value keyword should typically be set to the maximum distance that non-reacting atoms move during the simulation.

Fix bond/react creates and maintains two important dynamic groups of atoms when using the stabilization keyword. The first group contains all atoms currently involved in a reaction; this group is automatically thermostatted by an internally-created nve/limit integrator. The second group contains all atoms currently not involved in a reaction. This group should be used by a thermostat in order to time integrate the system. The name of this group of non-reacting atoms is created by appending ‘_REACT’ to the group-ID argument of the stabilization keyword, as shown in the second example above.

Note: When using reaction stabilization, you should generally not have a separate thermostat which acts on the ‘all’ group.

The group-ID set using the stabilization keyword can be an existing static group or a previously-unused group-ID. It cannot be specified as ‘all’. If the group-ID is previously unused, the fix bond/react command creates a dynamic group that is initialized to include all atoms. If the group-ID is that of an existing static group, the group is used as the parent group of new, internally-created dynamic group. In both cases, this new dynamic group is named by appending ‘_REACT’ to the group-ID, e.g. nvt_grp_REACT. By specifying an existing group, you may thermostat constant-topology parts of your system separately. The dynamic group contains only atoms not involved in a reaction at a given timestep, and therefore should be used by a subsequent system-wide time integrator such as nvt, npt, or nve, as shown in the second example above (full examples can be found at examples/PACKAGES/reaction). The time integration command should be placed after the fix bond/react command due to the internal dynamic grouping performed by fix bond/react.

Note: If the group-ID is an existing static group, react-group-IDs should also be specified as this static group, or a subset.

The reset_mol_ids keyword invokes the reset_mol_ids command after a reaction occurs, to ensure that molecule IDs are consistent with the new bond topology. The group-ID used for reset_mol_ids is the group-ID for this fix. Resetting molecule IDs is necessarily a global operation, and so can be slow for very large systems.

The following comments pertain to each react argument (in other words, can be customized for each reaction, or reaction step):

A check for possible new reaction sites is performed every Nevery timesteps. Nevery can be specified with an equal-style variable, whose value is rounded up to the nearest integer.

Three physical conditions must be met for a reaction to occur. First, an initiator atom pair must be identified within the reaction distance cutoffs. Second, the topology surrounding the initiator atom pair must match the topology of the pre-reaction template. Only atom types and bond connectivity are used to identify a valid reaction site (not bond types, etc.). Finally, any reaction constraints listed in the map file (see below) must be satisfied. If all of these conditions are met, the reaction site is eligible to be modified to match the post-reaction template.

An initiator atom pair will be identified if several conditions are met. First, a pair of atoms IJ within the specified react-group-ID of type itype and jtype must be separated by a distance between Rmin and Rmax. Rmin and Rmax can be specified with equal-style variables. For example, these reaction cutoffs can be a function of the reaction conversion using the following commands:
The following criteria are used if multiple candidate initiator atom pairs are identified within the cutoff distance: 1) If the initiator atoms in the pre-reaction template are not 1-2 neighbors (i.e. not directly bonded) the closest potential partner is chosen. 2) Otherwise, if the initiator atoms in the pre-reaction template are 1-2 neighbors (i.e. directly bonded) the farthest potential partner is chosen. 3) Then, if both an atom I and atom J have each other as their initiator partners, these two atoms are identified as the initiator atom pair of the reaction site. Note that it can be helpful to select unique atom types for the initiator atoms: if an initiator atom pair is identified, as described in the previous steps, but does not correspond to the same pair specified in the pre-reaction template, an otherwise eligible reaction could be prevented from occurring. Once this unique initiator atom pair is identified for each reaction, there could be two or more reactions that involve the same atom on the same timestep. If this is the case, only one such reaction is permitted to occur. This reaction is chosen randomly from all potential reactions involving the overlapping atom. This capability allows e.g. for different reaction pathways to proceed from identical reaction sites with user-specified probabilities.

The pre-reacted molecule template is specified by a molecule command. This molecule template file contains a sample reaction site and its surrounding topology. As described below, the initiator atom pairs of the pre-reacted template are specified by atom ID in the map file. The pre-reacted molecule template should contain as few atoms as possible while still completely describing the topology of all atoms affected by the reaction (which includes all atoms that change atom type or connectivity, and all bonds that change bond type). For example, if the force field contains dihedrals, the pre-reacted template should contain any atom within three bonds of reacting atoms.

Note: Small molecules, i.e. ones that have all their atoms contained within the reaction templates, never have edge atoms.

Note that some care must be taken when building a molecule template for a given simulation. All atom types in the pre-reacted template must be the same as those of a potential reaction site in the simulation. A detailed discussion of matching molecule template atom types with the simulation is provided on the molecule command page.

The post-reacted molecule template contains a sample of the reaction site and its surrounding topology after the reaction has occurred. It must contain the same number of atoms as the pre-reacted template (unless there are created atoms). A one-to-one correspondence between the atom IDs in the pre- and post-reacted templates is specified in the map file as described below. Note that during a reaction, an atom, bond, etc. type may change to one that was previously not present in the simulation. These new types must also be defined during the setup of a given simulation. A discussion of correctly handling this is also provided on the molecule command page.

Note: When a reaction occurs, it is possible that the resulting topology/atom (e.g. special bonds, dihedrals, etc.) exceeds that of the existing system and reaction templates. As when inserting molecules, enough space for this increased topology/atom must be reserved by using the relevant “extra” keywords to the read_data or create_box commands.

The map file is a text document with the following format:
A map file has a header and a body. The header of map file the contains one mandatory keyword and five optional keywords. The mandatory keyword is ‘equivalences’:

N equivalences = # of atoms N in the reaction molecule templates

The optional keywords are ‘edgeIDs’, ‘deleteIDs’, ‘chiralIDs’ and ‘constraints’:

N edgeIDs = # of edge atoms N in the pre-reacted molecule template
N deleteIDs = # of atoms N that are deleted
N createIDs = # of atoms N that are created
N chiralIDs = # of chiral centers N
N constraints = # of reaction constraints N

The body of the map file contains two mandatory sections and five optional sections. The first mandatory section begins with the keyword ‘InitiatorIDs’ and lists the two atom IDs of the initiator atom pair in the pre-reacted molecule template. The second mandatory section begins with the keyword ‘Equivalences’ and lists a one-to-one correspondence between atom IDs of the pre- and post-reacted templates. The first column is an atom ID of the pre-reacted molecule template, and the second column is the corresponding atom ID of the post-reacted molecule template. The first optional section begins with the keyword ‘EdgeIDs’ and lists the atom IDs of edge atoms in the pre-reacted molecule template. The second optional section begins with the keyword ‘DeleteIDs’ and lists the atom IDs of pre-reaction template atoms to delete. The third optional section begins with the keyword ‘CreateIDs’ and lists the atom IDs of the post-reaction template atoms to create. The fourth optional section begins with the keyword ‘ChiralIDs’ lists the atom IDs of chiral atoms whose handedness should be enforced. The fifth optional section begins with the keyword ‘Constraints’ and lists additional criteria that must be satisfied in order for the reaction to occur. Currently, there are six types of constraints available, as discussed below: ‘distance’, ‘angle’, ‘dihedral’, ‘arrhenius’, ‘rmsd’, and ‘custom’.

A sample map file is given below:

```plaintext
# this is a map file
7 equivalences
2 edgeIDs
InitiatorIDs
3
5
EdgeIDs
1
7
Equivalences
1 1
2 2
3 3
4 4
5 5
6 6
7 7
```

A user-specified set of atoms can be deleted by listing their pre-reaction template IDs in the DeleteIDs section. A deleted atom must still be included in the post-reaction molecule template, in which it cannot be bonded to an atom.
that is not deleted. In addition to deleting unwanted reaction by-products, this feature can be used to remove specific topologies, such as small rings, that may be otherwise indistinguishable.

Atoms can be created by listing their post-reaction template IDs in the CreateIDs section. A created atom should not be included in the pre-reaction template. The inserted positions of created atoms are determined by the coordinates of the post-reaction template, after optimal translation and rotation of the post-reaction template to the reaction site (using a fit with atoms that are neither created nor deleted). The modify_create keyword can be used to modify the default behavior when creating atoms. The modify_create keyword has two sub-keywords, fit and overlap. One or more of the sub-keywords may be used after the modify_create keyword. The fit sub-keyword can be used to specify which post-reaction atoms are used for the optimal translation and rotation of the post-reaction template. The fragmentID value of the fit sub-keyword must be the name of a molecule fragment defined in the post-reaction molecule template, and only atoms in this fragment are used for the fit. Atoms are created only if no current atom in the simulation is within a distance R of any created atom, including the effect of periodic boundary conditions if applicable. R is defined by the overlap sub-keyword. Note that the default value for R is 0.0, which will allow atoms to strongly overlap if you are inserting where other atoms are present. The velocity of each created atom is initialized in a random direction with a magnitude calculated from the instantaneous temperature of the reaction site.

The handedness of atoms that are chiral centers can be enforced by listing their IDs in the ChiralIDs section. A chiral atom must be bonded to four atoms with mutually different atom types. This feature uses the coordinates and types of the involved atoms in the pre-reaction template to determine handedness. Three atoms bonded to the chiral center are arbitrarily chosen, to define an oriented plane, and the relative position of the fourth bonded atom determines the chiral center's handedness.

Any number of additional constraints may be specified in the Constraints section of the map file. The constraint of type ‘distance’ has syntax as follows:

\[
distance \ ID1 \ ID2 \ r_{\text{min}} \ r_{\text{max}}
\]

where ‘distance’ is the required keyword, ID1 and ID2 are pre-reaction atom IDs (or molecule-fragment IDs, see below), and these two atoms must be separated by a distance between \( r_{\text{min}} \) and \( r_{\text{max}} \) for the reaction to occur.

The constraint of type ‘angle’ has the following syntax:

\[
angle \ ID1 \ ID2 \ ID3 \ a_{\text{min}} \ a_{\text{max}}
\]

where ‘angle’ is the required keyword, ID1, ID2 and ID3 are pre-reaction atom IDs (or molecule-fragment IDs, see below), and these three atoms must form an angle between \( a_{\text{min}} \) and \( a_{\text{max}} \) for the reaction to occur (where ID2 is the central atom). Angles must be specified in degrees. This constraint can be used to enforce a certain orientation between reacting molecules.

The constraint of type ‘dihedral’ has the following syntax:

\[
dihedral \ ID1 \ ID2 \ ID3 \ ID4 \ a_{\text{min}} \ a_{\text{max}} \ a_{\text{min}^2} \ a_{\text{max}^2}
\]

where ‘dihedral’ is the required keyword, and ID1, ID2, ID3 and ID4 are pre-reaction atom IDs (or molecule-fragment IDs, see below). Dihedral angles are calculated in the interval \((-180,180]\). Refer to the dihedral style documentation for further details on convention. If \( a_{\text{min}} \) is less than \( a_{\text{max}} \), these four atoms must form a dihedral angle greater than \( a_{\text{min}} \) and less than \( a_{\text{max}} \) for the reaction to occur. If \( a_{\text{min}} \) is greater than \( a_{\text{max}} \), these four atoms must form a dihedral angle greater than \( a_{\text{min}} \) or less than \( a_{\text{max}} \) for the reaction to occur. Angles must be specified in degrees. Optionally, a second range of permissible angles \( a_{\text{min}^2} \) - \( a_{\text{max}^2} \) can be specified.

For the ‘distance’, ‘angle’, and ‘dihedral’ constraints (explained above), atom IDs can be replaced by pre-reaction molecule-fragment IDs. The molecule-fragment ID must begin with a letter. The location of the ID is the geometric center of all atom positions in the fragment. The molecule fragment must have been defined in the molecule command for the pre-reaction template.

The constraint of type ‘arrhenius’ imposes an additional reaction probability according to the temperature-dependent Arrhenius equation:

\[
k = AT^n \ e^{\frac{-E_a}{kT}}
\]
The Arrhenius constraint has the following syntax:

```
arrhenius A n E_a seed
```

where ‘arrhenius’ is the required keyword, $A$ is the pre-exponential factor, $n$ is the exponent of the temperature dependence, $E_a$ is the activation energy (units of energy), and seed is a random number seed. The temperature is defined as the instantaneous temperature averaged over all atoms in the reaction site, and is calculated in the same manner as for example `compute temp/chunk`. Currently, there are no options for additional temperature averaging or velocity-biased temperature calculations. A uniform random number between 0 and 1 is generated using `seed`; if this number is less than the result of the Arrhenius equation above, the reaction is permitted to occur.

The constraint of type ‘rmsd’ has the following syntax:

```
rmsd RMSDmax molfragment
```

where ‘rmsd’ is the required keyword, and $RMSD_{max}$ is the maximum root-mean-square deviation between atom positions of the pre-reaction template and the local reaction site (distance units), after optimal translation and rotation of the pre-reaction template. Optionally, the name of a molecule fragment (of the pre-reaction template) can be specified by molfragment. If a molecule fragment is specified, only atoms that are part of this molecule fragment are used to determine the RMSD. A molecule fragment must have been defined in the molecule command for the pre-reaction template. For example, the molecule fragment could consist of only the backbone atoms of a polymer chain. This constraint can be used to enforce a specific relative position and orientation between reacting molecules.

The constraint of type ‘custom’ has the following syntax:

```
custom varstring
```

where ‘custom’ is the required keyword, and varstring is a variable expression. The expression must be a valid equal-style variable formula that can be read by the variable command, after any special reaction functions are evaluated. If the resulting expression is zero, the reaction is prevented from occurring; otherwise, it is permitted to occur. There are two special reaction functions available, ‘rxnsum’ and ‘rxnave’. These functions operate over the atoms in a given reaction site, and have one mandatory argument and one optional argument. The mandatory argument is the identifier for an atom-style variable. The second, optional argument is the name of a molecule fragment in the pre-reaction template, and can be used to operate over a subset of atoms in the reaction site. The ‘rxnsum’ function sums the atom-style variable over the reaction site, while the ‘rxnave’ returns the average value. For example, a constraint on the total potential energy of atoms involved in the reaction can be imposed as follows:

```
compute 1 all pe/atom # in LAMMPS input script
variable my_pe atom c_1 # in LAMMPS input script

custom "rxnsum(v_my_pe) > 100" # in Constraints section of map file
```

The above example prevents the reaction from occurring unless the total potential energy of the reaction site is above 100. The variable expression can be interpreted as the probability of the reaction occurring by using an inequality and the ‘random(x,y,z)’ function available as an equal-style variable input, similar to the ‘arrhenius’ constraint above.

By default, all constraints must be satisfied for the reaction to occur. In other words, constraints are evaluated as a series of logical values using the logical AND operator “&&”. More complex logic can be achieved by explicitly adding the logical AND operator “&&” or the logical OR operator “||” after a given constraint command. If a logical operator is specified after a constraint, it must be placed after all constraint parameters, on the same line as the constraint (one per line). Similarly, parentheses can be used to group constraints. The expression that results from concatenating all constraints should be a valid logical expression that can be read by the variable command after converting each constraint to a logical value. Because exactly one constraint is allowed per line, having a valid logical expression implies that left parentheses ‘(‘ should only appear before a constraint, and right parentheses ‘)’ should only appear after a constraint and before any logical operator.

Once a reaction site has been successfully identified, data structures within LAMMPS that store bond topology are updated to reflect the post-reacted molecule template. All force fields with fixed bonds, angles, dihedrals or impropers are supported.
A few capabilities to note: 1) You may specify as many react arguments as desired. For example, you could break down a complicated reaction mechanism into several reaction steps, each defined by its own react argument. 2) While typically a bond is formed or removed between the initiator atoms specified in the pre-reacted molecule template, this is not required. 3) By reversing the order of the pre- and post- reacted molecule templates in another react argument, you can allow for the possibility of one or more reverse reactions.

The optional keywords deal with the probability of a given reaction occurring as well as the stable equilibration of each reaction site as it occurs:

The prob keyword can affect whether or not an eligible reaction actually occurs. The fraction setting must be a value between 0.0 and 1.0, and can be specified with an equal-style variable. A uniform random number between 0.0 and 1.0 is generated and the eligible reaction only occurs if the random number is less than the fraction. Up to N reactions are permitted to occur, as optionally specified by the max_rxn keyword.

The stabilize_steps keyword allows for the specification of how many timesteps a reaction site is stabilized before being returned to the overall system thermostat. In order to produce the most physical behavior, this ‘reaction site equilibration time’ should be tuned to be as small as possible while retaining stability for a given system or reaction step. After a limited number of case studies, this number has been set to a default of 60 timesteps. Ideally, it should be individually tuned for each fix reaction step. Note that in some situations, decreasing rather than increasing this parameter will result in an increase in stability.

The custom_charges keyword can be used to specify which atoms’ atomic charges are updated. When the value is set to ‘no’, all atomic charges are updated to those specified by the post-reaction template (default). Otherwise, the value should be the name of a molecule fragment defined in the pre-reaction molecule template. In this case, only the atomic charges of atoms in the molecule fragment are updated.

The molecule keyword can be used to force the reaction to be intermolecular, intramolecular or either. When the value is set to ‘off’, molecule IDs are not considered when searching for reactions (default). When the value is set to ‘inter’, the initiator atoms must have different molecule IDs in order to be considered for the reaction. When the value is set to ‘intra’, only initiator atoms with the same molecule ID are considered for the reaction.

A few other considerations:

Optionally, you can enforce additional behaviors on reacting atoms. For example, it may be beneficial to force reacting atoms to remain at a certain temperature. For this, you can use the internally-created dynamic group named “bond_react_MASTER_group”, which consists of all atoms currently involved in a reaction. For example, adding the following command would add an additional thermostat to the group of all currently-reacting atoms:

```
fix 1 bond_react_MASTER_group temp/rescale 1 300 300 10 1
```

Note: This command must be added after the fix bond/react command, and will apply to all reactions.

Computationally, each timestep this fix operates, it loops over neighbor lists (for bond-forming reactions) and computes distances between pairs of atoms in the list. It also communicates between neighboring processors to coordinate which bonds are created and/or removed. All of these operations increase the cost of a timestep. Thus you should be cautious about invoking this fix too frequently.

You can dump out snapshots of the current bond topology via the dump local command.
17.23.4 Restart, fix_modify, output, run start/stop, minimize info

Cumulative reaction counts for each reaction are written to binary restart files. These values are associated with the reaction name (react-ID). Additionally, internally-created per-atom properties are stored to allow for smooth restarts. None of the fix_modify options are relevant to this fix.

This fix computes one statistic for each react argument that it stores in a global vector, of length ‘number of react arguments’, that can be accessed by various output commands. The vector values calculated by this fix are “intensive”.

These is 1 quantity for each react argument:
- (1) cumulative # of reactions occurred

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

When fix bond/react is ‘unfixed’, all internally-created groups are deleted. Therefore, fix bond/react can only be unfixed after unfixing all other fixes that use any group created by fix bond/react.

17.23.5 Restrictions

This fix is part of the REACTION package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

17.24 fix bond/swap command

17.24.1 Syntax

| fix ID group-ID bond/swap Nevery fraction cutoff seed |

- ID, group-ID are documented in fix command
- bond/swap = style name of this fix command
- Nevery = attempt bond swapping every this many steps
- fraction = fraction of group atoms to consider for swapping
- cutoff = distance at which swapping will be considered (distance units)
- seed = random # seed (positive integer)
17.24.2 Examples

| fix | 1 all bond/swap 50 0.5 1.3 598934 |

17.24.3 Description

In a simulation of polymer chains this command attempts to swap a pair of bonds, as illustrated below. This is done via Monte Carlo rules using the Boltzmann acceptance criterion, typically with the goal of equilibrating the polymer system more quickly. This fix is designed for use with idealized bead-spring polymer chains where each polymer is a linear chain of monomers, but LAMMPS does not check that is the case for your system.

Here are two use cases for this fix.

The first use case is for swapping bonds on two different chains, effectively grafting the end of one chain onto the other chain and vice versa. The purpose is to equilibrate the polymer chain conformations more rapidly than dynamics alone would do it, by enabling instantaneous large conformational changes in a dense polymer melt. The polymer chains should thus more rapidly converge to the proper end-to-end distances and radii of gyration.

A schematic of the kinds of bond swaps that can occur in this use case is shown here:

On the left, the red and blue chains have two monomers A1 and B1 close to each other, which are currently bonded to monomers A2 and B2 respectively within their own chains. The bond swap operation will attempt to delete the A1-A2 and B1-B2 bonds and replace them with A1-B2 and B1-A2 bonds. If the swap is energetically favorable, the two chains on the right are the result and each polymer chain has undergone a dramatic conformational change. This reference, (Sides) provides more details on the algorithm’s effectiveness for this use case.

The second use case is a collection of polymer chains with some fraction of their sites identified as “sticker” sites. Initially each polymer chain is isolated from the others in a topological sense, and there is an intra-chain bond between every pair of sticker sites on the same chain. Over time, bonds swap so that inter-molecular sticker bonds are created. This models a vitrification-style process whereby the polymer chains all become interconnected. For this use case, if angles are defined they should not include bonds between sticker sites.

The bond swapping operation is invoked once every Nevery timesteps. If any bond in the entire system is swapped, a re-build of the neighbor lists is triggered, since a swap alters the list of which neighbors are considered for pairwise interaction. At each invocation, each processor considers a random specified fraction of its atoms as potential swapping monomers for this timestep. Choosing a small fraction value can reduce the likelihood of a reverse swap occurring soon after an initial swap.

For each monomer A1, its neighbors are looped over as B1 monomers. For each A1,B1 an additional double loop of bond partners A2 of A1, and bond partners B2 of B1 a is performed. For each pair of A1-A2 and B1-B2 bonds to be eligible for swapping, the following 4 criteria must be met:

1. All 4 monomers must be in the fix group.
2. All 4 monomers must be owned by the processor (not ghost atoms). This insures that another processor does not attempt to swap bonds involving the same atoms on the same timestep. Note that this also means that bond pairs which straddle processor boundaries are not eligible for swapping on this step.

3. The distances between 4 pairs of atoms – (A1,A2), (B1,B2), (A1,B2), (B1,A2) – must all be less than the specified cutoff.

4. The molecule IDs of A1 and B1 must be the same (see below).

If an eligible B1 partner is found, the energy change due to swapping the 2 bonds is computed. This includes changes in pairwise, bond, and angle energies due to the altered connectivity of the 2 chains. Dihedral and improper interactions are not allowed to be defined when this fix is used.

If the energy decreases due to the swap operation, the bond swap is accepted. If the energy increases it is accepted with probability \( \exp(-\Delta E/kT) \) where \( \Delta E \) is the increase in energy, \( k \) is the Boltzmann constant, and \( T \) is the current temperature of the system.

**Note:** IMPORTANT: Whether the swap is accepted or rejected, no other swaps are attempted by this processor on this timestep. No other eligible 4-tuples of atoms are considered. This means that each processor will perform either a single swap or none on timesteps this fix is invoked.

The criterion for matching molecule IDs is how the first use case described above can be simulated while conserving chain lengths. This is done by setting up the molecule IDs for the polymer chains in a specific way, typically in the data file, read by the `read_data` command.

Consider a system of 6-mer chains. You have 2 choices. If the molecule IDs for monomers on each chain are set to 1,2,3,4,5,6 then swaps will conserve chain length. For a particular monomer there will be only one other monomer on another chain which is a potential swap partner. If the molecule IDs for monomers on each chain are set to 1,2,3,3,2,1 then swaps will conserve chain length but swaps will be able to occur at either end of a chain. Thus for a particular monomer there will be 2 possible swap partners on another chain. In this scenario, swaps can also occur within a single chain, i.e. the two ends of a chain swap with each other.

**Note:** If your simulation uses molecule IDs in the usual way, where all monomers on a single chain are assigned the same ID (different for each chain), then swaps will only occur within the same chain. If you assign the same molecule ID to all monomers in all chains then inter-chain swaps will occur, but they will not conserve chain length. Neither of these scenarios is probably what you want for this fix.

**Note:** When a bond swap occurs the image flags of monomers in the new polymer chains can become inconsistent. See the `dump` command for a discussion of image flags. This is not an issue for running dynamics, but can affect calculation of some diagnostic quantities or the printing of unwrapped coordinates to a dump file.

For the second use case described above, the molecule IDs for all sticker sites should be the same.

This fix computes a temperature each time it is invoked for use by the Boltzmann criterion. To do this, the fix creates its own compute of style `temp`, as if this command had been issued:

```
compute fix-ID_temp all temp
```

See the `compute temp` command for details. Note that the ID of the new compute is the fix-ID with underscore + “temp” appended and the group for the new compute is “all”, so that the temperature of the entire system is used.
Note that this is NOT the compute used by thermodynamic output (see the `thermo_style` command) with ID = `thermo_temp`. This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via the `compute_modify` command or print this temperature during thermodynamic output via the `thermo_style custom` command using the appropriate compute-ID. It also means that changing attributes of `thermo_temp` will have no effect on this fix.

### 17.24.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior. Also note that each processor generates possible swaps independently of other processors. Thus if you repeat the same simulation on a different number of processors, the specific swaps performed will be different.

The `fix_modify temp` option is supported by this fix. You can use it to assign a compute you have defined to this fix which will be used to compute the temperature for the Boltzmann criterion.

This fix computes two statistical quantities as a global 2-vector of output, which can be accessed by various output commands. The first component of the vector is the cumulative number of swaps performed by all processors. The second component of the vector is the cumulative number of swaps attempted (whether accepted or rejected). Note that a swap “attempt” only occurs when swap partners meeting the criteria described above are found on a particular timestep. The vector values calculated by this fix are “intensive”.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during energy minimization.

### 17.24.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

The settings of the “special_bond” command must be 0,1,1 in order to use this fix, which is typical of bead-spring chains with FENE or harmonic bonds. This means that pairwise interactions between bonded atoms are turned off, but are turned on between atoms two or three hops away along the chain backbone.

Currently, energy changes in dihedral and improper interactions due to a bond swap are not considered. Thus a simulation that uses this fix cannot use a dihedral or improper potential.

### 17.24.6 Related commands

`fix atom/swap`

### 17.24.7 Default

none

17.25  fix box/relax command

17.25.1 Syntax

```
fix ID group-ID box/relax keyword value ...
```

- ID, group-ID are documented in `fix` command
- box/relax = style name of this fix command

  one or more keyword value pairs may be appended
  
  keyword = iso or aniso or tri or x or y or z or xy or yz or xz or couple or nreset or vmax or dilate or scaleyz or scalexz or scalexy or fixedpoint
  
  iso or aniso or tri value = Ptarget = desired pressure (pressure units)
  
  x or y or z or xy or yz or xz value = Ptarget = desired pressure (pressure units)
  
  couple = none or xyz or xy or yz or xz
  
  nreset value = reset reference cell every this many minimizer iterations
  
  vmax value = fraction = max allowed volume change in one iteration
  
  dilate value = all or partial
  
  scaleyz value = yes or no = scale yz with lz
  
  scalexz value = yes or no = scale xz with lz
  
  scalexy value = yes or no = scale xy with ly
  
  fixedpoint values = x y z
  
  x, y, z = perform relaxation dilation/contraction around this point (distance units)

17.25.2 Examples

```
fix 1 all box/relax iso 0.0 vmax 0.001
fix 2 water box/relax aniso 0.0 dilate partial
fix 2 ice box/relax tri 0.0 couple xy nreset 100
```

17.25.3 Description

Apply an external pressure or stress tensor to the simulation box during an energy minimization. This allows the box size and shape to vary during the iterations of the minimizer so that the final configuration will be both an energy minimum for the potential energy of the atoms, and the system pressure tensor will be close to the specified external tensor. Conceptually, specifying a positive pressure is like squeezing on the simulation box; a negative pressure typically allows the box to expand.

The external pressure tensor is specified using one or more of the `iso`, `aniso`, `tri`, `x`, `y`, `z`, `xy`, `xz`, `yz`, and `couple` keywords. These keywords give you the ability to specify all 6 components of an external stress tensor, and to couple various of these components together so that the dimensions they represent are varied together during the minimization.

Orthogonal simulation boxes have 3 adjustable dimensions (x,y,z). Triclinic (non-orthogonal) simulation boxes have 6 adjustable dimensions (x,y,z,xy,xz,yz). The `create_box`, `read data`, and `read_restart` commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the `xy`, `xz`, `yz` tilt factors.

The target pressures `Ptarget` for each of the 6 components of the stress tensor can be specified independently via the `x`, `y`, `z`, `xy`, `xz`, `yz` keywords, which correspond to the 6 simulation box dimensions. For example, if the `y` keyword is used,
the y-box length will change during the minimization. If the \textit{xy} keyword is used, the xy tilt factor will change. A box dimension will not change if that component is not specified.

Note that in order to use the \textit{xy}, \textit{xz}, or \textit{yz} keywords, the simulation box must be triclinic, even if its initial tilt factors are 0.0.

When the size of the simulation box changes, all atoms are re-scaled to new positions, unless the keyword \textit{dilate} is specified with a value of \textit{partial}, in which case only the atoms in the fix group are re-scaled. This can be useful for leaving the coordinates of atoms in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

The \textit{scaleyz}, \textit{scalexz}, and \textit{scalexy} keywords control whether or not the corresponding tilt factors are scaled with the associated box dimensions when relaxing triclinic periodic cells. The default values \textit{yes} will turn on scaling, which corresponds to adjusting the linear dimensions of the cell while preserving its shape. Choosing \textit{no} ensures that the tilt factors are not scaled with the box dimensions. See below for restrictions and default values in different situations. In older versions of LAMMPS, scaling of tilt factors was not performed. The old behavior can be recovered by setting all three scale keywords to \textit{no}.

The \textit{fixedpoint} keyword specifies the fixed point for cell relaxation. By default, it is the center of the box. Whatever point is chosen will not move during the simulation. For example, if the lower periodic boundaries pass through (0,0,0), and this point is provided to \textit{fixedpoint}, then the lower periodic boundaries will remain at (0,0,0), while the upper periodic boundaries will move twice as far. In all cases, the particle positions at each iteration are unaffected by the chosen value, except that all particles are displaced by the same amount, different on each iteration.

Note: Applying an external pressure to tilt dimensions \textit{xy}, \textit{xz}, \textit{yz} can sometimes result in arbitrarily large values of the tilt factors, i.e. a dramatically deformed simulation box. This typically indicates that there is something badly wrong with how the simulation was constructed. The two most common sources of this error are applying a shear stress to a liquid system or specifying an external shear stress tensor that exceeds the yield stress of the solid. In either case the minimization may converge to a bogus conformation or not converge at all. Also note that if the box shape tilts to an extreme shape, LAMMPS will run less efficiently, due to the large volume of communication needed to acquire ghost atoms around a processor’s irregular-shaped sub-domain. For extreme values of tilt, LAMMPS may also lose atoms and generate an error.

Note: Performing a minimization with this fix is not a mathematically well-defined minimization problem. This is because the objective function being minimized changes if the box size/shape changes. In practice this means the minimizer can get “stuck” before you have reached the desired tolerance. The solution to this is to restart the minimizer from the new adjusted box size/shape, since that creates a new objective function valid for the new box size/shape. Repeat as necessary until the box size/shape has reached its new equilibrium.

The \textit{couple} keyword allows two or three of the diagonal components of the pressure tensor to be “coupled” together. The value specified with the keyword determines which are coupled. For example, \textit{xz} means the $P_{xx}$ and $P_{zz}$ components of the stress tensor are coupled. \textit{Xyz} means all 3 diagonal components are coupled. Coupling means two things: the instantaneous stress will be computed as an average of the corresponding diagonal components, and the coupled box dimensions will be changed together in lockstep, meaning coupled dimensions will be dilated or contracted by the same percentage every timestep. The \textit{Ptarget} values for any coupled dimensions must be identical. \textit{Couple xyz} can be used for a 2d simulation; the \textit{z} dimension is simply ignored.

The \textit{iso}, \textit{aniso}, and \textit{tri} keywords are simply shortcuts that are equivalent to specifying several other keywords together. The keyword \textit{iso} means couple all 3 diagonal components together when pressure is computed (hydrostatic pressure), and dilate/contract the dimensions together. Using “iso Ptarget” is the same as specifying these 4 keywords:
The keyword *aniso* means \(x, y, \) and \(z\) dimensions are controlled independently using the \(P_{xx}, P_{yy}, \) and \(P_{zz}\) components of the stress tensor as the driving forces, and the specified scalar external pressure. Using “aniso \(P_{\text{target}}\)” is the same as specifying these 4 keywords:

\[
\begin{align*}
\text{x \(P_{\text{target}}\)}
\text{y \(P_{\text{target}}\)}
\text{z \(P_{\text{target}}\)}
\text{couple \(xyz\)}
\end{align*}
\]

The keyword *tri* means \(x, y, z, xy, xz, \) and \(yz\) dimensions are controlled independently using their individual stress components as the driving forces, and the specified scalar pressure as the external normal stress. Using “tri \(P_{\text{target}}\)” is the same as specifying these 7 keywords:

\[
\begin{align*}
\text{x \(P_{\text{target}}\)}
\text{y \(P_{\text{target}}\)}
\text{z \(P_{\text{target}}\)}
\text{xy \(0.0\)}
\text{yz \(0.0\)}
\text{xz \(0.0\)}
\text{couple \(none\)}
\end{align*}
\]

The \(v_{\text{max}}\) keyword can be used to limit the fractional change in the volume of the simulation box that can occur in one iteration of the minimizer. If the pressure is not settling down during the minimization this can be because the volume is fluctuating too much. The specified fraction must be greater than 0.0 and should be \(<< 1.0\). A value of 0.001 means the volume cannot change by more than 1/10 of a percent in one iteration when \(\text{couple \(xyz\)}\) has been specified. For any other case it means no linear dimension of the simulation box can change by more than 1/10 of a percent.

With this fix, the potential energy used by the minimizer is augmented by an additional energy provided by the fix. The overall objective function then is:

\[
E = U + P_{t} (V - V_{0}) + E_{\text{strain}}
\]

where \(U\) is the system potential energy, \(P_{t}\) is the desired hydrostatic pressure, \(V\) and \(V_{0}\) are the system and reference volumes, respectively. \(E_{\text{strain}}\) is the strain energy expression proposed by Parrinello and Rahman (Parrinello1981). Taking derivatives of \(E\) w.r.t. the box dimensions, and setting these to zero, we find that at the minimum of the objective function, the global system stress tensor \(\mathbf{P}\) will satisfy the relation:

\[
\mathbf{P} = P_{t} \mathbf{I} + S_{t} \left( h_{0}^{-1} \right)^{\dagger} h_{0d}
\]

where \(\mathbf{I}\) is the identity matrix, \(h_{0}\) is the box dimension tensor of the reference cell, and \(h_{0d}\) is the diagonal part of \(h_{0}\). \(S_{t}\) is a symmetric stress tensor that is chosen by LAMMPS so that the upper-triangular components of \(\mathbf{P}\) equal the stress tensor specified by the user.

This equation only applies when the box dimensions are equal to those of the reference dimensions. If this is not the case, then the converged stress tensor will not equal that specified by the user. We can resolve this problem by periodically resetting the reference dimensions. The keyword \(n_{\text{reset}}\) controls how often this is done. If this keyword is not used, or is given a value of zero, then the reference dimensions are set to those of the initial simulation domain.
and are never changed. A value of \textit{nstep} means that every \textit{nstep} minimization steps, the reference dimensions are set to those of the current simulation domain. Note that resetting the reference dimensions changes the objective function and gradients, which sometimes causes the minimization to fail. This can be resolved by changing the value of \textit{nreset}, or simply continuing the minimization from a restart file.

\textbf{Note:} As normally computed, pressure includes a kinetic- energy or temperature-dependent component; see the \textit{compute pressure} command. However, atom velocities are ignored during a minimization, and the applied pressure(s) specified with this command are assumed to only be the virial component of the pressure (the non-kinetic portion). Thus if atoms have a non-zero temperature and you print the usual thermodynamic pressure, it may not appear the system is converging to your specified pressure. The solution for this is to either (a) zero the velocities of all atoms before performing the minimization, or (b) make sure you are monitoring the pressure without its kinetic component. The latter can be done by outputting the pressure from the pressure compute this command creates (see below) or a pressure compute you define yourself.

\textbf{Note:} Because pressure is often a very sensitive function of volume, it can be difficult for the minimizer to equilibrate the system the desired pressure with high precision, particularly for solids. Some techniques that seem to help are (a) use the “min_modify line quadratic” option when minimizing with box relaxations, (b) minimize several times in succession if need be, to drive the pressure closer to the target pressure, (c) relax the atom positions before relaxing the box, and (d) relax the box to the target hydrostatic pressure before relaxing to a target shear stress state. Also note that some systems (e.g. liquids) will not sustain a non-hydrostatic applied pressure, which means the minimizer will not converge.

This fix computes a temperature and pressure each timestep. The temperature is used to compute the kinetic contribution to the pressure, even though this is subsequently ignored by default. To do this, the fix creates its own computes of style “temp” and “pressure”, as if these commands had been issued:

\begin{verbatim}
compute fix-ID_temp group-ID temp
compute fix-ID_press group-ID pressure fix-ID_temp virial
\end{verbatim}

See the \textit{compute temp} and \textit{compute pressure} commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix_ID + underscore + “press”, and the group for the new computes is the same as the fix group. Also note that the pressure compute does not include a kinetic component.

Note that these are NOT the computes used by thermodynamic output (see the \textit{thermo_style} command) with ID = \textit{thermo_temp} and \textit{thermo_press}. This means you can change the attributes of this fix’s temperature or pressure via the \textit{compute_modify} command or print this temperature or pressure during thermodynamic output via the \textit{thermo_style custom} command using the appropriate compute-ID. It also means that changing attributes of \textit{thermo_temp} or \textit{thermo_press} will have no effect on this fix.

\section*{17.25.4 Restart, fix_modify, output, run start/stop, minimize info}

No information about this fix is written to binary restart files.

The \textit{fix_modify temp} and \textit{press} options are supported by this fix. You can use them to assign a \textit{compute} you have defined to this fix which will be used in its temperature and pressure calculation, as described above. Note that as described above, if you assign a pressure compute to this fix that includes a kinetic energy component it will affect the minimization, most likely in an undesirable way.
Note: If both the temp and press keywords are used in a single thermo_modify command (or in two separate commands), then the order in which the keywords are specified is important. Note that a pressure compute defines its own temperature compute as an argument when it is specified. The temp keyword will override this (for the pressure compute being used by fix box/relax), but only if the temp keyword comes after the press keyword. If the temp keyword comes before the press keyword, then the new pressure compute specified by the press keyword will be unaffected by the temp setting.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the pressure-volume energy, plus the strain energy, if it exists, as described above. The energy values reported at the end of a minimization run under “Minimization stats” include this energy, and so differ from what LAMMPS normally reports as potential energy. This fix does not support the fix_modify energy option, because that would result in double-counting of the fix energy in the minimization energy. Instead, the fix energy can be explicitly added to the potential energy using one of these two variants:

```
variable emin equal pe+f_1
variable emin equal pe+f_1/atoms
```

No parameter of this fix can be used with the start/stop keywords of the run command.

This fix is invoked during energy minimization, but not for the purpose of adding a contribution to the energy or forces being minimized. Instead it alters the simulation box geometry as described above.

17.25.5 Restrictions

Only dimensions that are available can be adjusted by this fix. Non-periodic dimensions are not available. z, xz, and yz, are not available for 2D simulations. xy, xz, and yz are only available if the simulation domain is non-orthogonal. The create_box, read data, and read_restart commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the xy, xz, yz tilt factors.

The scaleyz yes and scalexz yes keyword/value pairs can not be used for 2D simulations. scaleyz yes, scalexz yes, and scalexy yes options can only be used if the second dimension in the keyword is periodic, and if the tilt factor is not coupled to the barostat via keywords tri, yz, xz, and xy.

17.27 fix brownian/sphere command

17.28 fix brownian/asphere command

17.28.1 Syntax

fix ID group-ID style_name temp seed keyword args

- ID, group-ID are documented in fix command
- style_name = brownian or brownian/sphere or brownian/asphere
- temp = temperature
- seed = random number generator seed
- one or more keyword/value pairs may be appended
- keyword = rng or dipole or gamma_r_eigen or gamma_t_eigen or gamma_r or gamma_t or rotation_temp or planar_rotation
  
  - rng value = uniform or gaussian or none
    uniform = use uniform random number generator
    gaussian = use gaussian random number generator
    none = turn off noise
  - dipole value = mux and muy and muz for brownian/asphere
    mux, muy, and muz = update orientation of dipole having direction (mux,*muy*,
    →muz*) in body frame of rigid body
  - gamma_r_eigen values = gr1 and gr2 and gr3 for brownian/asphere
    gr1, gr2, and gr3 = diagonal entries of body frame rotational friction tensor
  - gamma_r values = gr for brownian/sphere
    gr = magnitude of the (isotropic) rotational friction tensor
  - gamma_t_eigen values = gt1 and gt2 and gt3 for brownian/asphere
    gt1, gt2, and gt3 = diagonal entries of body frame translational friction tensor
  - gamma_t values = gt for brownian and brownian/sphere
    gt = magnitude of the (isotropic) translational friction tensor
  - rotation_temp values = T for brownian/sphere and brownian/asphere
    T = rotation temperature, which can be different then temp when out of equilibrium
  - planar_rotation values = None (constrains rotational diffusion to be in xy plane if in 3D)

```

(continues on next page)
17.28.3 Description

Perform Brownian Dynamics time integration to update position, velocity, dipole orientation (for spheres) and quaternion orientation (for ellipsoids, with optional dipole update as well) of all particles in the fix group in each timestep. Brownian Dynamics uses Newton’s laws of motion in the limit that inertial forces are negligible compared to viscous forces. The stochastic equation of motion for the center of mass positions is

\[
dr = \gamma_t^{-1} F dt + \sqrt{2k_B T \gamma_t^{-1/2}} dW_t,
\]

in the lab-frame (i.e. \(\gamma_t\) is not diagonal, but only depends on orientation and so the noise is still additive).

The rotational motion for the spherical and ellipsoidal particles is not as simple an expression, but is chosen to replicate the Boltzmann distribution for the case of conservative torques (see (Ilie) or (Delong)).

For the style brownian, only the positions of the particles are updated. This is therefore suitable for point particle simulations.

For the style brownian/sphere, the positions of the particles are updated, and a dipole slaved to the spherical orientation is also updated. This style therefore requires the hybrid atom style \text{atom_style dipole} and \text{atom_style sphere}. The equation of motion for the dipole is

\[
\mu(t + dt) = \frac{\mu(t) + \omega \times \mu dt}{|\mu(t) + \omega \times \mu|}
\]

which correctly reproduces a Boltzmann distribution of orientations and rotational diffusion moments (see (Ilie)) when

\[
\omega = \frac{T}{\gamma_r} + \sqrt{\frac{2k_B T_{rot}}{\gamma_r}} \frac{dW}{dt},
\]

with \(dW\) being a random number with zero mean and variance \(dt\) and \(T_{rot}\) is \text{rotation_temp}.

For the style brownian/asphere, the center of mass positions and the quaternions of ellipsoidal particles are updated. This fix style is suitable for equations of motion where the rotational and translational friction tensors can be diagonalized in a certain (body) reference frame. In this case, the rotational equation of motion is updated via the quaternion

\[
q(t + dt) = \frac{q(t) + dq}{|q(t) + dq|}
\]

which correctly reproduces a Boltzmann distribution of orientations and rotational diffusion moments (see (Ilie)) when the quaternion step given by

\[
dq = \Psi \omega dt
\]

where \(\Psi\) has rows \((-q_3, -q_2, -q_3), (q_0, -q_3, q_2), (q_3, q_0, -q_1)\), and \((-q_2, q_1, q_0)\). \(\omega\) is evaluated in the body frame of reference where the friction tensor is diagonal. See (Delong) for more details of a similar algorithm.

\[\text{Note:}\quad \text{This integrator does not by default assume a relationship between the rotational and translational friction tensors, though such a relationship should exist in the case of no-slip boundary conditions between the particles and the surrounding (implicit) solvent. E.g. in the case of spherical particles, the condition } \gamma_t = 3\gamma_r/\sigma^2 \text{ must be explicitly accounted for by setting } \text{gamma}_t \text{ to }3\times \text{ and } \text{gamma}_r \text{ to } \times (\text{where } \sigma \text{ is the spherical diameter). A similar (though more complex) relationship holds for ellipsoids and rod-like particles. The translational diffusion and rotational diffusion are given by } \text{temp/gamma}_t \text{ and } \text{rotation_temp/gamma}_r.\]

17.28. fix brownian/asphere command 1139
Note: Temperature computation using the `compute temp` will not correctly compute temperature of these overdamped dynamics since we are explicitly neglecting inertial effects. Furthermore, this time integrator does not add the stochastic terms or viscous terms to the force and/or torques. Rather, they are just added in to the equations of motion to update the degrees of freedom.

If the `rng` keyword is used with the `uniform` value, then the noise is generated from a uniform distribution (see (Dunweg) for why this works). This is the same method of noise generation as used in `fix_langevin`.

If the `rng` keyword is used with the `gaussian` value, then the noise is generated from a gaussian distribution. Typically this added complexity is unnecessary, and one should be fine using the `uniform` value for reasons argued in (Dunweg).

If the `rng` keyword is used with the `none` value, then the noise terms are set to zero.

The `gamma_t` keyword sets the (isotropic) translational viscous damping. Required for (and only compatible with) `brownian` and `brownian/sphere`. The units of `gamma_t` are mass/time.

The `gamma_r` keyword sets the (isotropic) rotational viscous damping. Required for (and only compatible with) `brownian/sphere`. The units of `gamma_r` are mass*length**2/time.

The `gamma_r_eigen`, and `gamma_t_eigen` keywords are the eigenvalues of the rotational and viscous damping tensors (having the same units as their isotropic counterparts). Required for (and only compatible with) `brownian/asphere`. For a 2D system, the first two values of `gamma_r_eigen` must be inf (only rotation in xy plane), and the third value of `gamma_t_eigen` must be inf (only diffusion in xy plane).

If the `dipole` keyword is used, then the dipole moments of the particles are updated as described above. Only compatible with `brownian/asphere` (as `brownian/sphere` updates dipoles automatically).

If the `rotation_temp` keyword is used, then the rotational diffusion will be occur at this prescribed temperature instead of `temp`. Only compatible with `brownian/sphere` and `brownian/asphere`.

If the `planar_rotation` keyword is used, then rotation is constrained to the xy plane in a 3D simulation. Only compatible with `brownian/sphere` and `brownian/asphere` in 3D.

Note: For style `brownian/asphere`, the components `gamma_t_eigen` = (x,x,x) and `gamma_r_eigen` = (y,y,y), the dynamics will replicate those of the `brownian/sphere` style with `gamma_t` = x and `gamma_r` = y.

17.28.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. No global or per-atom quantities are stored by this fix for access by various output commands.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during energy minimization.
17.28.5 Restrictions

The style `brownian/sphere` fix requires that atoms store torque and angular velocity (omega) as defined by the `atom_style sphere` command. The style `brownian/asphere` fix requires that atoms store torque and quaternions as defined by the `atom_style ellipsoid` command. If the `dipole` keyword is used, they must also store a dipole moment as defined by the `atom_style dipole` command.

This fix is part of the BROWNIAN package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

17.28.6 Related commands

`fix propel/self, fix langevin, fix nve/sphere`.

17.28.7 Default

The default for `rng` is `uniform`. The default for the rotational and translational friction tensors are the identity tensor.

17.29 fix charge/regulation command

17.29.1 Syntax

```
fix ID group-ID charge/regulation cation_type anion_type keyword value(s)
```

- `ID, group-ID` are documented in fix command
- `charge/regulation` = style name of this fix command
- `cation_type` = atom type of free cations
- `anion_type` = atom type of free anions
- zero or more keyword/value pairs may be appended

```
keyword = pH, pKa, pKb, pIp, pIm, pKs, acid_type, base_type, lunit_nm, temp, ...
         = tempfixid, nevery, nmc, rxd, seed, tag, group, onlysalt, pmcmoves
pH value = pH of the solution (can be specified as an equal-style variable)
pKa value = acid dissociation constant (in the -log10 representation)
pKb value = base dissociation constant (in the -log10 representation)
pIp value = activity (effective concentration) of free cations (in the -log10 representation)
pIm value = activity (effective concentration) of free anions (in the -log10 representation)
pKs value = solvent self-dissociation constant (in the -log10 representation)
acid_type = atom type of acid groups
base_type = atom type of base groups
lunit_nm value = unit length used by LAMMPS (# in the units of nanometers)
```
temp value = temperature
tempfixid value = fix ID of temperature thermostat
nevery value = invoke this fix every nevery steps
nmc value = number of charge regulation MC moves to attempt every nevery steps
rxd value = cutoff distance for acid/base reaction
seed value = random # seed (positive integer)
tag value = yes or no (yes: The code assigns unique tags to inserted ions; no: The tag of all inserted ions is "0")
group value = group-ID, inserted ions are assigned to group group-ID. Can be used multiple times to assign inserted ions to multiple groups.
onlysalt values = flag charge_cation charge_anion.
flag = yes or no (yes: the fix performs only ion insertion/deletion, no: perform acid/base dissociation and ion insertion/deletion)
charge_cation, charge_anion = value of cation/anion charge, must be an integer (only specify if flag = yes)

17.29.2 Examples

```
fix chareg all charge/regulation 1 2 acid_type 3 base_type 4 pKa 5.0 pKb 6.0 pH 7.0 pIp -3.0 pIm 3.0 nevery 200 nmc 200 seed 123 tempfixid fT
```

```
fix chareg all charge/regulation 1 2 pIp 3 pIm 3 onlysalt yes 2 -1 seed 123 tag yes temp -1.0
```

17.29.3 Description

This fix performs Monte Carlo (MC) sampling of charge regulation and exchange of ions with a reservoir as discussed in (Curk1) and (Curk2). The implemented method is largely analogous to the grand-reaction ensemble method in (Landsgesell). The implementation is parallelized, compatible with existing LAMMPS functionalities, and applicable to any system utilizing discrete, ionizable groups or surface sites.

Specifically, the fix implements the following three types of MC moves, which discretely change the charge state of individual particles and insert ions into the systems: $A \leftrightarrow A^- + X^+$, $B \leftrightarrow B^+ + X^-$, and $\emptyset \leftrightarrow Z^+ + X^- Z^-$. In the former two types of reactions, Monte Carlo moves alter the charge value of specific atoms (A, B) and simultaneously insert a counterion to preserve the charge neutrality of the system, modeling the dissociation/association process. The last type of reaction performs grand canonical MC exchange of ion pairs with a (fictitious) reservoir.

In our implementation “acid” refers to particles that can attain charge $q = \{0, -1\}$ and “base” to particles with $q = \{0, 1\}$, whereas the MC exchange of free ions allows any integer charge values of $Z^+$ and $Z^-$. Here we provide several practical examples for modeling charge regulation effects in solvated systems. An acid ionization reaction ($A \leftrightarrow A^- + H^+$) can be defined via a single line in the input file

```
fix acid_reaction all charge/regulation 2 3 acid_type 1 pH 7.0 pKa 5.0 pIp 7.0 pIm 7.0
```

where the fix attempts to charge A (discharge $A^-$) to $A^- (A)$ and insert (delete) a proton (atom type 2). Besides, the fix implements self-ionization reaction of water $\emptyset \leftrightarrow H^+ + OH^-$.

However, this approach is highly inefficient at $pH \approx 7$ when the concentration of both protons and hydroxyl ions is low, resulting in a relatively low acceptance rate of MC moves.

A more efficient way is to allow salt ions to participate in ionization reactions, which can be easily achieved via
where particles of atom type 4 and 5 are the salt cations and anions, both at activity (effective concentration) of $10^{-2}$ mol/l, see \cite{Curk1} and \cite{Landsgesell} for more details.

We could have simultaneously added a base ionization reaction ($B \rightleftharpoons B^+ + OH^-$)

```
fix acid_base_reaction all charge/regulation 2 3 acid_type 1 base_type 6 pH 7.0 pKa 5.0 pKb 6.0 pIp 7.0 pIm 7.0
```

where the fix will attempt to charge $B$ (discharge $B^+$) to $B^+ (B)$ and insert (delete) a hydroxyl ion $OH^-$ of atom type 3.

Dissociated ions and salt ions can be combined into a single particle type, which reduces the number of necessary MC moves and increases sampling performance, see \cite{Curk1}. The $H^+$ and monovalent salt cation ($S^+$) are combined into a single particle type, $X^+ = \{H^+, S^+\}$. In this case “pIp” refers to the effective concentration of the combined cation type $X^+$ and its value is determined by $10^{-\text{pIp}} = 10^{-\text{pH}} + 10^{-\text{pSp}}$, where $10^{-\text{pSp}}$ is the effective concentration of salt cations. For example, at pH=7 and pSp=6 we would find pIp=5.958 and the command that performs reactions with combined ions could read,

```
fix acid_reaction_combined all charge/regulation 2 3 acid_type 1 pH 7.0 pKa 5.0 pIp 5.958 pIm 5.958
```

If neither the acid or the base type is specified, for example,

```
fix salt_reaction all charge/regulation 4 5 pIp 2.0 pIm 2.0
```

the fix simply inserts or deletes an ion pair of a free cation (atom type 4) and a free anion (atom type 5) as done in a conventional grand-canonical MC simulation. Multivalent ions can be inserted (deleted) by using the \textit{onlysalt} keyword.

The fix is compatible with LAMMPS sub-packages such as \textit{molecule} or \textit{rigid}. The acid and base particles can be part of larger molecules or rigid bodies. Free ions that are inserted to or deleted from the system must be defined as single particles (no bonded interactions allowed) and cannot be part of larger molecules or rigid bodies. If \textit{molecule} package is used, all inserted ions have a molecule ID equal to zero.

Note that LAMMPS implicitly assumes a constant number of particles (degrees of freedom). Since using this fix alters the total number of particles during the simulation, any thermostat used by LAMMPS, such as NVT or Langevin, must use a dynamic calculation of system temperature. This can be achieved by specifying a dynamic temperature compute (e.g. \texttt{dtemp}) and using it with the desired thermostat, e.g. a Langevin thermostat:

```
compute dtemp all temp
compute_modify dtemp dynamic yes
fix fT all langevin 1.0 1.0 1.0 123
fix_modify fT temp dtemp
```

The units of pH, pKa, pKb, pIp, pIm are considered to be in the standard -log10 representation assuming reference concentration $\rho_0 = \text{mol/l}$. For example, in the dilute ideal solution limit, the concentration of free cations will be $c_1 = 10^{-\text{pIp}} \text{mol/l}$. To perform the internal unit conversion, the the value of the LAMMPS unit length must be specified in nanometers via \texttt{lunit\_nm}. The default value is set to the Bjerrum length in water at room temperature (0.71 nm), \texttt{lunit\_nm} = 0.71.

The temperature used in MC acceptance probability is set by \textit{temp}. This temperature should be the same as the temperature set by the molecular dynamics thermostat. For most purposes, it is probably best to use \textit{tempfixid} keyword which dynamically sets the temperature equal to the chosen MD thermostat temperature, in the example above we assumed the thermostat fix-ID is \texttt{fT}. The inserted particles attain a random velocity corresponding to the specified temperature. Using \textit{tempfixid} overrides any fixed temperature set by \textit{temp}.
The \textit{rxd} keyword can be used to restrict the inserted/deleted counterions to a specific radial distance from an acid or base particle that is currently participating in a reaction. This can be used to simulate more realistic reaction dynamics. If \( \text{rxd} = 0 \) or \( \text{rxd} > L/2 \), where \( L \) is the smallest box dimension, the radial restriction is automatically turned off and free ion can be inserted or deleted anywhere in the simulation box.

If the \textit{tag yes} is used, every inserted atom gets a unique tag ID, otherwise, the tag of every inserted atom is set to 0. \textit{tag yes} might cause an integer overflow in very long simulations since the tags are unique to every particle and thus increase with every successful particle insertion.

The \textit{pmcmoves} keyword sets the relative probability of attempting the three types of MC moves (reactions): acid charging, base charging, and ion pair exchange. The \textit{fix} only attempts to perform particle charging MC moves if \textit{acid_type} or \textit{base_type} is defined. Otherwise, \textit{fix} only performs free ion insertion/deletion. For example, if \textit{acid_type} is not defined, \textit{pmcA} is automatically set to 0. The vector \textit{pmcmoves} is automatically normalized, for example, if set to \textit{pmcmoves} 0 0.33 0.33, the vector would be normalized to [0,0.5,0.5].

The \textit{only_salt} option can be used to perform multivalent grand-canonical ion-exchange moves. If \textit{only_salt yes} is used, no charge exchange is performed, only ion insertion/deletion (\textit{pmcmoves} is set to [0,0,1]), but ions can be multivalent. In the example above, an MC move would consist of three ion insertion/deletion to preserve the charge neutrality of the system.

The \textit{group} keyword can be used to add inserted particles to a specific group-ID. All inserted particles are automatically added to group \textit{all}.

\section*{17.29.4 Output}

This fix computes a global vector of length 8, which can be accessed by various output commands. The vector values are the following global quantities:

- 1 = cumulative MC attempts
- 2 = cumulative MC successes
- 3 = current # of neutral acid atoms
- 4 = current # of -1 charged acid atoms
- 5 = current # of neutral base atoms
- 6 = current # of +1 charged base atoms
- 7 = current # of free cations
- 8 = current # of free anions

\section*{17.29.5 Restrictions}

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

The \textit{atom_style}, used must contain the charge property, for example, the style could be \textit{charge} or \textit{full}. Only usable for 3D simulations. Atoms specified as free ions cannot be part of rigid bodies or molecules and cannot have bonding interactions. The scheme is limited to integer charges, any atoms with non-integer charges will not be considered by the fix.

All interaction potentials used must be continuous, otherwise the MD integration and the particle exchange MC moves do not correspond to the same equilibrium ensemble. For example, if an \textit{lj/cut} pair style is used, the LJ potential must be shifted so that it vanishes at the cutoff. This can be easily achieved using the \textit{pair_modify} command, i.e., by using: \textit{pair_modify shift yes}. 
Note: Region restrictions are not yet implemented.

<td>myCMAP energy yes</td>
</tr>
</tbody>
</table>
17.30.3 Description

This command enables CMAP cross-terms to be added to simulations which use the CHARMM force field. These are relevant for any CHARMM model of a peptide or protein sequences that is 3 or more amino-acid residues long; see (Buck) and (Brooks) for details, including the analytic energy expressions for CMAP interactions. The CMAP cross-terms add additional potential energy contributions to pairs of overlapping phi psi dihedrals of amino-acids, which are important to properly represent their conformational behavior.

The examples/cmap directory has a sample input script and data file for a small peptide, that illustrates use of the fix cmap command.

As in the example above, this fix should be used before reading a data file that contains a listing of CMAP interactions. The filename specified should contain the CMAP parameters for a particular version of the CHARMM force field. Two such files are including in the lammps/potentials directory: charmm22.cmap and charmm36.cmap.

The data file read by the “read_data” must contain the topology of all the CMAP interactions, similar to the topology data for bonds, angles, dihedrals, etc. Specially it should have a line like this in its header section:

```
N crossterms
```

where N is the number of CMAP cross-terms. It should also have a section in the body of the data file like this with N lines:

```
CMAP
   1 1 8 10 12 18 20
   2 5 18 20 22 25 27
   [ ... ]
   N 3 314 315 317 318 330
```

The first column is an index from 1 to N to enumerate the CMAP terms; it is ignored by LAMMPS. The second column is the “type” of the interaction; it is an index into the CMAP force field file. The remaining 5 columns are the atom IDs of the atoms in the two 4-atom dihedrals that overlap to create the CMAP 5-body interaction. Note that the “crossterm” and “CMAP” keywords for the header and body sections match those specified in the read_data command following the data file name; see the read_data page for more details.

A data file containing CMAP cross-terms can be generated from a PDB file using the charmm2lammps.pl script in the tools/ch2lmp directory of the LAMMPS distribution. The script must be invoked with the optional “-cmap” flag to do this; see the tools/ch2lmp/README file for more information.

The potential energy associated with CMAP interactions can be output as described below. It can also be included in the total potential energy of the system, as output by the thermo_style command, if the fix_modify energy command is used, as in the example above. See the note below about how to include the CMAP energy when performing an energy minimization.

17.30.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the list of CMAP cross-terms to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify energy option is supported by this fix to add the potential energy of the CMAP interactions to both the global potential energy and peratom potential energies of the system as part of thermodynamic output or output by the compute pe/atom command. The default setting for this fix is fix_modify energy yes.
The fix_modify virial option is supported by this fix to add the contribution due to the CMAP interactions to both the global pressure and per-atom stress of the system via the compute pressure and compute stress/atom commands. The former can be accessed by thermodynamic output. The default setting for this fix is fix_modify virial yes.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the potential energy discussed above. The scalar value calculated by this fix is “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.

Note: If you want the potential energy associated with the CMAP terms forces to be included in the total potential energy of the system (the quantity being minimized), you MUST not disable the fix_modify energy option for this fix.

17.30.5 Restrictions

To function as expected this fix command must be issued before a read_data command but after a read_restart command.

This fix can only be used if LAMMPS was built with the MOLECULE package. See the Build package page for more info.

17.30.6 Related commands

fix_modify, read_data

17.30.7 Default

17.31 fix colvars command

17.31.1 Syntax

```
fix ID group-ID colvars configfile keyword values ...
```

- ID, group-ID are documented in fix command
- colvars = style name of this fix command
- configfile = the configuration file for the colvars module
- keyword = input or output or seed or tstat
input arg = colvars.state file name or prefix or NULL (default: NULL)
output arg = output filename prefix (default: out)
seed arg = seed for random number generator (default: 1966)
unwrap arg = yes or no
    use unwrapped coordinates in collective variables (default: yes)
tstat arg = fix id of a thermostat or NULL (default: NULL)

17.31.2 Examples

fix mtd all colvars peptide.colvars.inp seed 2122 input peptide.colvars.state output peptide
fix abf all colvars colvars.inp tstat 1

17.31.3 Description

This fix interfaces LAMMPS to the collective variables (Colvars) library, which allows to calculate potentials of mean force (PMFs) for any set of colvars, using different sampling methods: currently implemented are the Adaptive Biasing Force (ABF) method, metadynamics, Steered Molecular Dynamics (SMD) and Umbrella Sampling (US) via a flexible harmonic restraint bias.

This documentation describes only the fix colvars command itself and LAMMPS specific parts of the code. The full documentation of the colvars library is available as this supplementary PDF document

The Colvars library is developed at https://github.com/colvars/colvars A detailed discussion of its implementation is in (Fiorin).

There are some example scripts for using this package with LAMMPS in the examples/PACKAGES/colvars directory.

The only mandatory argument to the fix is the filename to the colvars input file that contains the input that is independent from the MD program in which the colvars library has been integrated.

The group-ID entry is ignored. The collective variable module will always apply to the entire system and there can only be one instance of the colvars fix at a time. The colvars fix will only communicate the minimum information necessary and the colvars library supports multiple, completely independent collective variables, so there is no restriction to functionality by limiting the number of colvars fixes.

The input keyword allows to specify a state file that would contain the restart information required in order to continue a calculation from a prerecorded state. Fix colvars records it state in binary restart files, so when using the read_restart command, this is usually not needed.

The output keyword allows to specify the output prefix. All output files generated will use this prefix followed by the “.colvars.” and a word like “state” or “traj”.

The seed keyword contains the seed for the random number generator that will be used in the colvars module.

The unwrap keyword controls whether wrapped or unwrapped coordinates are passed to the colvars library for calculation of the collective variables and the resulting forces. The default is yes, i.e. to use the image flags to reconstruct the absolute atom positions. Setting this to no will use the current local coordinates that are wrapped back into the simulation cell at each re-neighboring instead.

The tstat keyword can be either NULL or the label of a thermostating fix that thermostats all atoms in the fix colvars group. This will be used to provide the colvars module with the current thermostat target temperature.
17.31.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the current status of the colvars module into binary restart files. This is in addition to the text mode status file that is written by the colvars module itself and the kind of information in both files is identical.

The fix_modify energy option is supported by this fix to add the energy change from the biasing force added by Colvars to the global potential energy of the system as part of thermodynamic output. The default setting for this fix is fix_modify energy no.

The fix_modify configfile <config file> option allows to add settings from an additional config file to the colvars module. This option can only be used, after the system has been initialized with a run command.

The fix_modify config <quoted string> option allows to add settings from inline strings. Those have to fit on a single line when enclosed in a pair of double quotes ("), or can span multiple lines when bracketed by a pair of triple double quotes ("""), like python embedded documentation.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the Colvars energy mentioned above. The scalar value calculated by this fix is “extensive”.

17.31.5 Restrictions

This fix is part of the COLVARS package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

There can only be one colvars fix active at a time. Since the interface communicates only the minimum amount of information and colvars module itself can handle an arbitrary number of collective variables, this is not a limitation of functionality.

17.31.6 Related commands

fix smd, fix spring, fix plumed

17.31.7 Default

The default options are input = NULL, output = out, seed = 1966, unwrap yes, and tstat = NULL.

*fix 1 all controller 10000 0.2 0.5 0 2000 v_avpe -3.785 tcontrol

17.32.3 Description

This fix enables control of a LAMMPS simulation using a control loop feedback mechanism known as a proportional-integral-derivative (PID) controller. The basic idea is to define a “process variable” which is a quantity that can be monitored during a running simulation. A desired target value is chosen for the process variable. A “control variable” is also defined which is an adjustable attribute of the running simulation, which the process variable will respond to. The PID controller continuously adjusts the control variable based on the difference between the process variable and the target.

Here are examples of ways in which this fix can be used. The examples/pid directory contains a script that implements the simple thermostat.

<table>
<thead>
<tr>
<th>Goal</th>
<th>process variable</th>
<th>control variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Simple thermostat</td>
<td>instantaneous T</td>
<td>thermostat target T</td>
</tr>
<tr>
<td>Find melting temperature</td>
<td>average PE per atom</td>
<td>thermostat target T</td>
</tr>
<tr>
<td>Control pressure in non-periodic system</td>
<td>force on wall</td>
<td>position of wall</td>
</tr>
</tbody>
</table>

Note: For this fix to work, the control variable must actually induce a change in a running LAMMPS simulation. Typically this will only occur if there is some other command (e.g. a thermostat fix) which uses the control variable as an input parameter. This could be done directly or indirectly, e.g. the other command uses a variable as input whose formula uses the control variable. The other command should alter its behavior dynamically as the variable changes.

Note: If there is a command you think could be used in this fashion, but does not currently allow a variable as an input parameter, please notify the LAMMPS developers. It is often not difficult to enable a command to use a variable as an input parameter.
The group specified with this command is ignored. However, note that the process variable may be defined by calculations performed by computes and fixes which store their own “group” definitions.

The PID controller is invoked once each Nevery timesteps.

The PID controller is implemented as a discretized version of the following dynamic equation:

\[ \frac{dc}{dt} = \bar{E} - \alpha(K_p e + K_c \sum_{i=1}^{n} e_i + K_d (c_n - c_{n-1})) \]

where \( c \) is the continuous time analog of the control variable, \( e = pvar-setpoint \) is the error in the process variable, and \( \alpha, K_p, K_c, \) and \( K_d \) are constants set by the corresponding keywords described above. The discretized version of this equation is:

\[ c_n = \bar{E} c_{n-1} - \alpha \left( K_p \tau e_n + K_c \tau^2 \sum_{i=1}^{n} e_i + K_d (c_n - c_{n-1}) \right) \]

where \( \tau = \text{Nevery} \cdot \text{timestep} \) is the time interval between updates, and the subscripted variables indicate the values of \( c \) and \( e \) at successive updates.

From the first equation, it is clear that if the three gain values \( K_p, K_c, K_d \) are dimensionless constants, then \( \alpha \) must have units of \([\text{unit cvar}] / [\text{unit pvar}] / [\text{unit time}]\) e.g. \([\text{eV/K/ps}]\). The advantage of this unit scheme is that the value of the constants should be invariant under a change of either the MD timestep size or the value of Nevery. Similarly, if the LAMMPS unit style is changed, it should only be necessary to change the value of \( \alpha \) to reflect this, while leaving \( K_p, K_c, \) and \( K_d \) unaltered.

When choosing the values of the four constants, it is best to first pick a value and sign for \( \alpha \) that is consistent with the magnitudes and signs of \( pvar \) and \( cvar \). The magnitude of \( K_p \) should then be tested over a large positive range keeping \( K_c = K_d = 0 \). A good value for \( K_p \) will produce a fast response in \( pvar \), without overshooting the setpoint. For many applications, proportional feedback is sufficient, and so \( K_c = K_d = 0 \) can be used. In cases where there is a substantial lag time in the response of \( pvar \) to a change in \( cvar \), this can be counteracted by increasing \( K_d \). In situations where \( pvar \) plateaus without reaching setpoint, this can be counteracted by increasing \( K_c \). In the language of Charles Dickens, \( K_p \) represents the error of the present, \( K_c \) the error of the past, and \( K_d \) the error yet to come.

Because this fix updates \( cvar \), but does not initialize its value, the initial value is that assigned by the user in the input script via the internal-style variable command. This value is used (by the other LAMMPS command that used the variable) until this fix performs its first update of \( cvar \) after Nevery timesteps. On the first update, the value of the derivative term is set to zero, because the value of \( c_n - 1 \) is not yet defined.

The process variable \( pvar \) can be specified as the output of a compute or fix or the evaluation of a variable. In each case, the compute, fix, or variable must produce a global quantity, not a per-atom or local quantity.

If \( pvar \) begins with “c_”, a compute ID must follow which has been previously defined in the input script and which generates a global scalar or vector. See the individual compute doc page for details. If no bracketed integer is appended, the scalar calculated by the compute is used. If a bracketed integer is appended, the Ith value of the vector calculated by the compute is used. Users can also write code for their own compute styles and add them to LAMMPS.

If \( pvar \) begins with “f_”, a fix ID must follow which has been previously defined in the input script and which generates a global scalar or vector. See the individual fix page for details. Note that some fixes only produce their values on certain timesteps, which must be compatible with when fix controller references the values, or else an error results. If no bracketed integer is appended, the scalar calculated by the fix is used. If a bracketed integer is appended, the Ith value of the vector calculated by the fix is used. Users can also write code for their own fix style and add them to LAMMPS.

If \( pvar \) begins with “v_”, a variable name must follow which has been previously defined in the input script. Only equal-style variables can be referenced. See the variable command for details. Note that variables of style equal define a formula which can reference individual atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of specifying the process variable.
The target value *setpoint* for the process variable must be a numeric value, in whatever units *pvar* is defined for.

The control variable *cvar* must be the name of an *internal-style variable* previously defined in the input script. Note that it is not specified with a “v_” prefix, just the name of the variable. It must be an internal-style variable, because this fix updates its value directly. Note that other commands can use an equal-style versus internal-style variable interchangeably.

### 17.32.4 Restart, fix_modify, output, run start/stop, minimize info

Currently, no information about this fix is written to *binary restart files*. None of the *fix_modify* options are relevant to this fix.

This fix produces a global vector with 3 values which can be accessed by various *output commands*. The values can be accessed on any timestep, though they are only updated on timesteps that are a multiple of *Nevery*.

The three values are the most recent updates made to the control variable by each of the 3 terms in the PID equation above. The first value is the proportional term, the second is the integral term, the third is the derivative term.

The units of the vector values will be whatever units the control variable is in. The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

### 17.32.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 17.33 fix damping/cundall command

**17.33.1 Syntax**

```plaintext
fix ID group-ID damping/cundall gamma_l gamma_a keyword values ...
```

- ID, group-ID are documented in *fix* command
- damping/cundall = style name of this fix command
- gamma_l = linear damping coefficient (dimensionless)
- gamma_a = angular damping coefficient (dimensionless)
• zero or more keyword/value pairs may be appended

keyword = scale
  scale values = type ratio or v_name
  type = atom type (1-N)
  ratio = factor to scale the damping coefficients by
  v_name = reference to atom style variable name

17.33.2 Examples

```plaintext
fix 1 all damping/cundall 0.8 0.8
fix 1 all damping/cundall 0.8 0.5 scale 3 2.5
fix a all damping/cundall 0.8 0.5 scale v_radscale
```

17.33.3 Description

Add damping force and torque to finite-size spherical particles in the group following the model of Cundall, 1987, as implemented in other granular physics code (e.g., Yade-DEM, PFC).

The damping is constructed to always have negative mechanical power with respect to the current velocity/angular velocity to ensure dissipation of kinetic energy. If used without additional thermostating (to add kinetic energy to the system), it has the effect of slowly (or rapidly) freezing the system; hence it can also be used as a simple energy minimization technique.

The magnitude of the damping force/torque \( F_d/T_d \) is a fraction \( \gamma \in [0; 1] \) of the current force/torque \( F/T \) on the particle. Damping is applied component-by-component in each direction \( k \in \{x, y, z\} \):

\[
F_{dk} = -\gamma l F_k \text{sign}(F_k v_k)
T_{dk} = -\gamma a T_k \text{sign}(T_k \omega_k)
\]

The larger the coefficients, the faster the kinetic energy is reduced.

If the optional keyword scale is used, \( \gamma l \) and \( \gamma a \) can be scaled up or down by the specified factor for atoms. This factor can be set for different atom types and thus the scale keyword used multiple times followed by the atom type and the associated scale factor. Alternately the scaling factor can be computed for each atom (e.g. based on its radius) by using an atom-style variable.

Note: The damping force/torque is computed based on the force/torque at the moment this fix is invoked. Any force/torque added after this fix, e.g., by fix addforce or fix addtorque will not be damped. When performing simulations with gravity, invoking fix gravity after this fix will maintain the specified gravitational acceleration.

Note: This scheme is dependent on the coordinates system and does not correspond to realistic physical processes. It is constructed for numerical convenience and efficacy.

This non-viscous damping presents the following advantages:

1. damping is independent of velocity, equally damping regions with distinct natural frequencies,
2. damping affects acceleration and vanishes for steady uniform motion of the particles,
3. damping parameter \( \gamma \) is dimensionless and does not require scaling.
17.33.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is modifying forces/torques. Default is the outermost level.

The forces/torques due to this fix are imposed during an energy minimization, invoked by the minimize command. This fix should only be used with damped dynamics minimizers that allow for non-conservative forces. See the min_style command for details.

17.33.5 Restrictions

This fix is part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This fix requires that atoms store torque and a radius as defined by the atom_style sphere command.

### 17.34.3 Description

Change the volume and/or shape of the simulation box during a dynamics run. Orthogonal simulation boxes have 3 adjustable parameters (x,y,z). Triclinic (non-orthogonal) simulation boxes have 6 adjustable parameters (x,y,z,xy,xz,yz). Any or all of them can be adjusted independently and simultaneously by this command.

This fix can be used to perform non-equilibrium MD (NEMD) simulations of a continuously strained system. See the \texttt{fix nvt/sllod} and \texttt{compute temp/deform} commands for more details. Note that simulation of a continuously extended system (extensional flow) can be modeled using the \texttt{UEF package} and its \texttt{fix commands}.

For the \texttt{x}, \texttt{y}, and \texttt{z} parameters, the associated dimension cannot be shrink-wrapped. For the \texttt{xy}, \texttt{yz}, and \texttt{xz} parameters, the associated second dimension cannot be shrink-wrapped. Dimensions not varied by this command can be periodic or non-periodic. Dimensions corresponding to unspecified parameters can also be controlled by a \texttt{fix npt} or \texttt{fix nph} command.

The size and shape of the simulation box at the beginning of the simulation run were either specified by the \texttt{create_box} or \texttt{read_data} or \texttt{read_restart} command used to setup the simulation initially if it is the first run, or they are the values from the end of the previous run. The \texttt{create_box}, \texttt{read_data}, and \texttt{read_restart} commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the \texttt{xy}, \texttt{xz}, \texttt{yz} tilt factors. If \texttt{fix deform} changes the \texttt{xy}, \texttt{xz}, \texttt{yz} tilt factors, then the simulation box must be triclinic, even if its initial tilt factors are 0.0.

As described below, the desired simulation box size and shape at the end of the run are determined by the parameters of the \texttt{fix deform} command. Every Nth timestep during the run, the simulation box is expanded, contracted, or tilted to ramped values between the initial and final values.

For the \texttt{x}, \texttt{y}, and \texttt{z} parameters, this is the meaning of their styles and values.

The \texttt{final}, \texttt{delta}, \texttt{scale}, \texttt{vel}, and \texttt{erate} styles all change the specified dimension of the box via “constant displacement” which is effectively a “constant engineering strain rate”. This means the box dimension changes linearly with time from its initial to final value.

For style \texttt{final}, the final \texttt{lo} and \texttt{hi} boundaries of a dimension are specified. The values can be in lattice or box distance units. See the discussion of the \texttt{units} keyword below.
For style *delta*, plus or minus changes in the lo/hi box boundaries of a dimension are specified. The values can be in lattice or box distance units. See the discussion of the units keyword below.

For style *scale*, a multiplicative factor to apply to the box length of a dimension is specified. For example, if the initial box length is 10, and the factor is 1.1, then the final box length will be 11. A factor less than 1.0 means compression.

For style *vel*, a velocity at which the box length changes is specified in units of distance/time. This is effectively a “constant engineering strain rate”, where rate = V/L0 and L0 is the initial box length. The distance can be in lattice or box distance units. See the discussion of the units keyword below. For example, if the initial box length is 100 Angstroms, and V is 10 Angstroms/ps, then after 10 ps, the box length will have doubled. After 20 ps, it will have tripled.

The *erate* style changes a dimension of the box at a “constant engineering strain rate”. The units of the specified strain rate are 1/time. See the *units* command for the time units associated with different choices of simulation units, e.g. picoseconds for “metal” units). Tensile strain is unitless and is defined as delta/L0, where L0 is the original box length and delta is the change relative to the original length. The box length L as a function of time will change as

\[ L(t) = L0 \left(1 + \text{erate} \times dt\right) \]

where dt is the elapsed time (in time units). Thus if *erate* R is specified as 0.1 and time units are picoseconds, this means the box length will increase by 10% of its original length every picosecond. I.e. strain after 1 ps = 0.1, strain after 2 ps = 0.2, etc. R = -0.01 means the box length will shrink by 1% of its original length every picosecond. Note that for an “engineering” rate the change is based on the original box length, so running with R = 1 for 10 picoseconds expands the box length by a factor of 11 (strain of 10), which is different that what the *trate* style would induce.

The *trate* style changes a dimension of the box at a “constant true strain rate”. Note that this is not an “engineering strain rate”, as the other styles are. Rather, for a “true” rate, the rate of change is constant, which means the box dimension changes non-linearly with time from its initial to final value. The units of the specified strain rate are 1/time. See the *units* command for the time units associated with different choices of simulation units, e.g. picoseconds for “metal” units). Tensile strain is unitless and is defined as delta/L0, where L0 is the original box length and delta is the change relative to the original length.

The box length L as a function of time will change as

\[ L(t) = L0 \exp(\text{trate} \times dt) \]

where dt is the elapsed time (in time units). Thus if *trate* R is specified as ln(1.1) and time units are picoseconds, this means the box length will increase by 10% of its current (not original) length every picosecond. I.e. strain after 1 ps = 0.1, strain after 2 ps = 0.21, etc. R = ln(2) or ln(3) means the box length will double or triple every picosecond. R = ln(0.99) means the box length will shrink by 1% of its current length every picosecond. Note that for a “true” rate the change is continuous and based on the current length, so running with R = ln(2) for 10 picoseconds does not expand the box length by a factor of 11 as it would with *erate*, but by a factor of 1024 since the box length will double every picosecond.

Note that to change the volume (or cross-sectional area) of the simulation box at a constant rate, you can change multiple dimensions via *erate or trate*. E.g. to double the box volume in a picosecond picosecond, you could set “x erate M”, “y erate M”, “z erate M”, with M = pow(2,1/3) - 1 = 0.26, since if each box dimension grows by 26%, the box volume doubles. Or you could set “x trate M”, “y trate M”, “z trate M”, with M = ln(1.26) = 0.231, and the box volume would double every picosecond.

The *volume* style changes the specified dimension in such a way that the box volume remains constant while other box dimensions are changed explicitly via the styles discussed above. For example, “x scale 1.1 y scale 1.1 z volume” will shrink the z box length as the x,y box lengths increase, to keep the volume constant (product of x,y,z lengths). If “x scale 1.1 z volume” is specified and parameter y is unspecified, then the z box length will shrink as x increases to keep the product of x,z lengths constant. If “x scale 1.1 y volume z volume” is specified, then both the y,z box lengths will shrink as x increases to keep the volume constant (product of x,y,z lengths). In this case, the y,z box lengths shrink so as to keep their relative aspect ratio constant.

For solids or liquids, note that when one dimension of the box is expanded via fix deform (i.e. tensile strain), it may be physically undesirable to hold the other 2 box lengths constant (unspecified by fix deform) since that implies a density
change. Using the `volume` style for those 2 dimensions to keep the box volume constant may make more physical sense, but may also not be correct for materials and potentials whose Poisson ratio is not 0.5. An alternative is to use `fix npt aniso` with zero applied pressure on those 2 dimensions, so that they respond to the tensile strain dynamically.

The `wiggle` style oscillates the specified box length dimension sinusoidally with the specified amplitude and period. I.e. the box length \( L \) as a function of time is given by

\[ L(t) = L_0 + A \sin(2\pi \frac{t}{T_p}) \]

where \( L_0 \) is its initial length. If the amplitude \( A \) is a positive number the box initially expands, then contracts, etc. If \( A \) is negative then the box initially contracts, then expands, etc. The amplitude can be in lattice or box distance units. See the discussion of the units keyword below.

The `variable` style changes the specified box length dimension by evaluating a variable, which presumably is a function of time. The variable with `name1` must be an `equal-style variable` and should calculate a change in box length in units of distance. Note that this distance is in box units, not lattice units; see the discussion of the `units` keyword below. The formula associated with variable `name1` can reference the current timestep. Note that it should return the “change” in box length, not the absolute box length. This means it should evaluate to 0.0 when invoked on the initial timestep of the run following the definition of fix deform. It should evaluate to a value > 0.0 to dilate the box at future times, or a value < 0.0 to compress the box.

The variable `name2` must also be an `equal-style variable` and should calculate the rate of box length change, in units of distance/time, i.e. the time-derivative of the `name1` variable. This quantity is used internally by LAMMPS to reset atom velocities when they cross periodic boundaries. It is computed internally for the other styles, but you must provide it when using an arbitrary variable.

Here is an example of using the `variable` style to perform the same box deformation as the `wiggle` style formula listed above, where we assume that the current timestep = 0.

```
variable A equal 5.0
variable Tp equal 10.0
variable displace equal "v_A * sin(2*PI * step*dt/v_Tp)"
variable rate equal "2*PI*v_A/v_Tp * cos(2*PI * step*dt/v_Tp)"
fix 2 all deform 1 x variable v_displace v_rate remap v
```

For the `scale`, `vel`, `erate`, `trate`, `volume`, `wiggle`, and `variable` styles, the box length is expanded or compressed around its mid point.

For the `xy`, `xz`, and `yz` parameters, this is the meaning of their styles and values. Note that changing the tilt factors of a triclinic box does not change its volume.

The `final`, `delta`, `vel`, and `erate` styles all change the shear strain at a “constant engineering shear strain rate”. This means the tilt factor changes linearly with time from its initial to final value.

For style `final`, the final tilt factor is specified. The value can be in lattice or box distance units. See the discussion of the units keyword below.

For style `delta`, a plus or minus change in the tilt factor is specified. The value can be in lattice or box distance units. See the discussion of the units keyword below.

For style `vel`, a velocity at which the tilt factor changes is specified in units of distance/time. This is effectively an “engineering shear strain rate”, where rate = \( V/L_0 \) and \( L_0 \) is the initial box length perpendicular to the direction of shear. The distance can be in lattice or box distance units. See the discussion of the units keyword below. For example, if the initial tilt factor is 5 Angstroms, and the V is 10 Angstroms/ps, then after 1 ps, the tilt factor will be 15 Angstroms. After 2 ps, it will be 25 Angstroms.

The `erate` style changes a tilt factor at a “constant engineering shear strain rate”. The units of the specified shear strain rate are 1/time. See the `units` command for the time units associated with different choices of simulation units, e.g.
picoseconds for “metal” units). Shear strain is unitless and is defined as offset/length, where length is the box length perpendicular to the shear direction (e.g. y box length for xy deformation) and offset is the displacement distance in the shear direction (e.g. x direction for xy deformation) from the unstrained orientation.

The tilt factor $T$ as a function of time will change as

$$T(t) = T_0 + L_0 \cdot e^{rate \cdot dt}$$

where $T_0$ is the initial tilt factor, $L_0$ is the original length of the box perpendicular to the shear direction (e.g. y box length for xy deformation), and $dt$ is the elapsed time (in time units). Thus if $erate$ is specified as 0.1 and time units are picoseconds, this means the shear strain will increase by 0.1 every picosecond. I.e. if the xy shear strain was initially 0.0, then strain after 1 ps = 0.1, strain after 2 ps = 0.2, etc. Thus the tilt factor would be 0.0 at time 0, 0.1*ybox at 1 ps, 0.2*ybox at 2 ps, etc, where ybox is the original y box length. $R = 1$ or $2$ means the tilt factor will increase by 1 or 2 every picosecond. $R = -0.01$ means a decrease in shear strain by 0.01 every picosecond.

The $trate$ style changes a tilt factor at a “constant true shear strain rate”. Note that this is not an “engineering shear strain rate”, as the other styles are. Rather, for a “true” rate, the rate of change is constant, which means the tilt factor changes non-linearly with time from its initial to final value. The units of the specified shear strain rate are 1/time. See the $units$ command for the time units associated with different choices of simulation units, e.g. picoseconds for “metal” units). Shear strain is unitless and is defined as offset/length, where length is the box length perpendicular to the shear direction (e.g. y box length for xy deformation) and offset is the displacement distance in the shear direction (e.g. x direction for xy deformation) from the unstrained orientation.

The tilt factor $T$ as a function of time will change as

$$T(t) = T_0 \cdot e^{trate \cdot dt}$$

where $T_0$ is the initial tilt factor and $dt$ is the elapsed time (in time units). Thus if $trate$ is specified as ln(1.1) and time units are picoseconds, this means the shear strain or tilt factor will increase by 10% every picosecond. I.e. if the xy shear strain was initially 0.1, then strain after 1 ps = 0.11, strain after 2 ps = 0.121, etc. $R = \ln(2)$ or $\ln(3)$ means the tilt factor will double or triple every picosecond. $R = \ln(0.99)$ means the tilt factor will shrink by 1% every picosecond. Note that the change is continuous, so running with $R = \ln(2)$ for 10 picoseconds does not change the tilt factor by a factor of 10, but by a factor of 1024 since it doubles every picosecond. Note that the initial tilt factor must be non-zero to use the $trate$ option.

Note that shear strain is defined as the tilt factor divided by the perpendicular box length. The $erate$ and $trate$ styles control the tilt factor, but assume the perpendicular box length remains constant. If this is not the case (e.g. it changes due to another fix deform parameter), then this effect on the shear strain is ignored.

The $wiggle$ style oscillates the specified tilt factor sinusoidally with the specified amplitude and period. I.e. the tilt factor $T$ as a function of time is given by

$$T(t) = T_0 + A \cdot \sin(2\pi t/T_p)$$

where $T_0$ is its initial value. If the amplitude $A$ is a positive number the tilt factor initially becomes more positive, then more negative, etc. If $A$ is negative then the tilt factor initially becomes more negative, then more positive, etc. The amplitude can be in lattice or box distance units. See the discussion of the units keyword below.

The $variable$ style changes the specified tilt factor by evaluating a variable, which presumably is a function of time. The variable with $name1$ must be an $equal$-style variable and should calculate a change in tilt in units of distance. Note that this distance is in box units, not lattice units; see the discussion of the $units$ keyword below. The formula associated with variable $name1$ can reference the current timestep. Note that it should return the “change” in tilt factor, not the absolute tilt factor. This means it should evaluate to 0.0 when invoked on the initial timestep of the run following the definition of fix deform.

The variable $name2$ must also be an $equal$-style variable and should calculate the rate of tilt change, in units of distance/time, i.e. the time-derivative of the $name1$ variable. This quantity is used internally by LAMMPS to reset atom velocities when they cross periodic boundaries. It is computed internally for the other styles, but you must provide it when using an arbitrary variable.
Here is an example of using the `variable` style to perform the same box deformation as the `wiggle` style formula listed above, where we assume that the current timestep = 0.

```
variable A equal 5.0
variable Tp equal 10.0
variable displace equal "v_A * sin(2*PI * step*dt/v_Tp)"
variable rate equal "2*PI*v_A/v_Tp * cos(2*PI * step*dt/v_Tp)"
fix 2 all deform 1 xy variable v_displace v_rate remap v
```

All of the tilt styles change the `xy`, `xz`, `yz` tilt factors during a simulation. In LAMMPS, tilt factors (`xy`, `xz`, `yz`) for triclinic boxes are normally bounded by half the distance of the parallel box length. See the discussion of the `flip` keyword below, to allow this bound to be exceeded, if desired.

For example, if `xlo = 2` and `xhi = 12`, then the `x` box length is 10 and the `xy` tilt factor must be between -5 and 5. Similarly, both `xz` and `yz` must be between -(xhi-xlo)/2 and +(yhi-ylo)/2. Note that this is not a limitation, since if the maximum tilt factor is 5 (as in this example), then configurations with tilt = …, -15, -5, 5, 15, 25, … are all equivalent.

To obey this constraint and allow for large shear deformations to be applied via the `xy`, `xz`, or `yz` parameters, the following algorithm is used. If `prd` is the associated parallel box length (10 in the example above), then if the tilt factor exceeds the accepted range of -5 to 5 during the simulation, then the box is flipped to the other limit (an equivalent box) and the simulation continues. Thus for this example, if the initial `xy` tilt factor was 0.0 and “`xy final 100.0`” was specified, then during the simulation the `xy` tilt factor would increase from 0.0 to 5.0, the box would be flipped so that the tilt factor becomes -5.0, the tilt factor would increase from -5.0 to 5.0, the box would be flipped again, etc. The flip occurs 10 times and the final tilt factor at the end of the simulation would be 0.0. During each flip event, atoms are remapped into the new box in the appropriate manner.

The one exception to this rule is if the first dimension in the tilt factor (`x` for `xy`) is non-periodic. In that case, the limits on the tilt factor are not enforced, since flipping the box in that dimension does not change the atom positions due to non-periodicity. In this mode, if you tilt the system to extreme angles, the simulation will simply become inefficient due to the highly skewed simulation box.

Each time the box size or shape is changed, the `remap` keyword determines whether atom positions are remapped to the new box. If `remap` is set to `x` (the default), atoms in the fix group are remapped; otherwise they are not. Note that their velocities are not changed, just their positions are altered. If `remap` is set to `v`, then any atom in the fix group that crosses a periodic boundary will have a delta added to its velocity equal to the difference in velocities between the `lo` and `hi` boundaries. Note that this velocity difference can include tilt components, e.g. a delta in the `x` velocity when an atom crosses the `y` periodic boundary. If `remap` is set to `none`, then neither of these remappings take place.

Conceptually, setting `remap` to `x` forces the atoms to deform via an affine transformation that exactly matches the box deformation. This setting is typically appropriate for solids. Note that though the atoms are effectively “moving” with the box over time, it is not due to their having a velocity that tracks the box change, but only due to the remapping. By contrast, setting `remap` to `v` is typically appropriate for fluids, where you want the atoms to respond to the change in box size/shape on their own and acquire a velocity that matches the box change, so that their motion will naturally track the box without explicit remapping of their coordinates.

**Note:** When non-equilibrium MD (NEMD) simulations are performed using this fix, the option “`remap v`” should normally be used. This is because `fix nvt/sllod` adjusts the atom positions and velocities to induce a velocity profile that matches the changing box size/shape. Thus atom coordinates should NOT be remapped by fix deform, but velocities SHOULD be when atoms cross periodic boundaries, since that is consistent with maintaining the velocity profile already created by fix nvt/sllod. LAMMPS will warn you if the `remap` setting is not consistent with fix nvt/sllod.
**Note:** For non-equilibrium MD (NEMD) simulations using “remap v” it is usually desirable that the fluid (or flowing material, e.g. granular particles) stream with a velocity profile consistent with the deforming box. As mentioned above, using a thermostat such as fix nvt/sllod or fix lavgevin (with a bias provided by compute temp/deform), will typically accomplish that. If you do not use a thermostat, then there is no driving force pushing the atoms to flow in a manner consistent with the deforming box. E.g. for a shearing system the box deformation velocity may vary from 0 at the bottom to 10 at the top of the box. But the stream velocity profile of the atoms may vary from -5 at the bottom to +5 at the top. You can monitor these effects using the fix ave/chunk, compute temp/deform, and compute temp/profile commands. One way to induce atoms to stream consistent with the box deformation is to give them an initial velocity profile, via the velocity ramp command, that matches the box deformation rate. This also typically helps the system come to equilibrium more quickly, even if a thermostat is used.

**Note:** If a fix rigid is defined for rigid bodies, and remap is set to x, then the center-of-mass coordinates of rigid bodies will be remapped to the changing simulation box. This will be done regardless of whether atoms in the rigid bodies are in the fix deform group or not. The velocity of the centers of mass are not remapped even if remap is set to v, since fix nvt/sllod does not currently do anything special for rigid particles. If you wish to perform a NEMD simulation of rigid particles, you can either thermostat them independently or include a background fluid and thermostat the fluid via fix nvt/sllod.

The flip keyword allows the tilt factors for a triclinic box to exceed half the distance of the parallel box length, as discussed above. If the flip value is set to yes, the bound is enforced by flipping the box when it is exceeded. If the flip value is set to no, the tilt will continue to change without flipping. Note that if you apply large deformations, this means the box shape can tilt dramatically LAMMPS will run less efficiently, due to the large volume of communication needed to acquire ghost atoms around a processor’s irregular-shaped sub-domain. For extreme values of tilt, LAMMPS may also lose atoms and generate an error.

The units keyword determines the meaning of the distance units used to define various arguments. A box value selects standard distance units as defined by the units command, e.g. Angstroms for units = real or metal. A lattice value means the distance units are in lattice spacings. The lattice command must have been previously used to define the lattice spacing. Note that the units choice also affects the vel style parameters since it is defined in terms of distance/time. Also note that the units keyword does not affect the variable style. You should use the xlat, ylat, zlat keywords of the thermo_style command if you want to include lattice spacings in a variable formula.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
17.34.4 Restart, fix_modify, output, run start/stop, minimize info

This fix will restore the initial box settings from binary restart files, which allows the fix to be properly continue deformation, when using the start/stop options of the run command. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands.

This fix can perform deformation over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

17.34.5 Restrictions

You cannot apply x, y, or z deformations to a dimension that is shrink-wrapped via the boundary command.

You cannot apply xy, yz, or xz deformations to a second dimension (y in xy) that is shrink-wrapped via the boundary command.

17.34.6 Related commands

change_box

17.34.7 Default

The option defaults are remap = x, flip = yes, and units = lattice.

17.35 fix deposit command

17.35.1 Syntax

\[ \text{fix ID group-ID deposit N type M seed keyword values ...} \]

- ID, group-ID are documented in fix command
- deposit = style name of this fix command
- N = # of atoms or molecules to insert
- type = atom type to assign to inserted atoms (offset for molecule insertion)
- M = insert a single atom or molecule every M steps
- seed = random # seed (positive integer)
- one or more keyword/value pairs may be appended to args
- keyword = region or id or global or local or near or gaussian or attempt or rate or vx or vy or vz or mol or rigid or shake or units
  - region value = region-ID
  - region-ID = ID of region to use as insertion volume
  - id value = max or next
  - max = atom ID for new atom(s) is max ID of all current atoms plus one
  - next = atom ID for new atom(s) increments by one for every deposition
global values = lo hi
   lo,hi = put new atom/molecule a distance lo-hi above all other atoms (distance units)

local values = lo hi delta
   lo,hi = put new atom/molecule a distance lo-hi above any nearby atom beneath it (distance units)
   delta = lateral distance within which a neighbor is considered "nearby" (distance units)
near value = R
   R = only insert atom/molecule if further than R from existing particles (distance units)

gaussian values = xmid ymid zmid sigma
   xmid,ymid,zmid = center of the gaussian distribution (distance units)
   sigma = width of gaussian distribution (distance units)

attempt value = Q
   Q = attempt a single insertion up to Q times

rate value = V
   V = z velocity (y in 2d) at which insertion volume moves (velocity units)

vx values = vxlo vxhi
   vxlo,vxhi = range of x velocities for inserted atom/molecule (velocity units)

vy values = vylo vyhi
   vylo,vyhi = range of y velocities for inserted atom/molecule (velocity units)

vz values = vzlo vzhi
   vzlo,vzhi = range of z velocities for inserted atom/molecule (velocity units)

target values = tx ty tz
   tx,ty,tz = location of target point (distance units)

mol value = template-ID
   template-ID = ID of molecule template specified in a separate molecule command

molfrac values = f1 f2 ... fN
   f1 to fN = relative probability of creating each of N molecules in template-ID

rigid value = fix-ID
   fix-ID = ID of fix rigid/small command

shake value = fix-ID
   fix-ID = ID of fix shake command

orient values = rx ry rz
   rx,ry,rz = vector to randomly rotate an inserted molecule around

units value = lattice or box
   lattice = the geometry is defined in lattice units
   box = the geometry is defined in simulation box units

17.35.2 Examples

fix 3 all deposit 1000 2 100 29494 region myblock local 1.0 1.0 1.0 units box
fix 2 newatoms deposit 10000 1 500 12345 region disk near 2.0 vz -1.0 -0.8
fix 4 sputter deposit 1000 2 500 12235 region sphere vz -1.0 -1.0 target 5.0 5.0 0.0
   -units lattice
fix 5 insert deposit 200 2 100 777 region disk gaussian 5.0 5.0 9.0 1.0 units box
17.35.3 Description

Insert a single atom or molecule into the simulation domain every \( M \) timesteps until \( N \) atoms or molecules have been inserted. This is useful for simulating deposition onto a surface. For the remainder of this doc page, a single inserted atom or molecule is referred to as a “particle”.

If inserted particles are individual atoms, they are assigned the specified atom type. If they are molecules, the type of each atom in the inserted molecule is specified in the file read by the \texttt{molecule} command, and those values are added to the specified atom type. E.g. if the file specifies atom types 1,2,3, and those are the atom types you want for inserted molecules, then specify \texttt{type} = 0. If you specify \texttt{type} = 2, the in the inserted molecule will have atom types 3,4,5.

All atoms in the inserted particle are assigned to two groups: the default group “all” and the group specified in the fix deposit command (which can also be “all”).

If you are computing temperature values which include inserted particles, you will want to use the \texttt{compute_modify} dynamic option, which insures the current number of atoms is used as a normalizing factor each time the temperature is computed.

Care must be taken that inserted particles are not too near existing atoms, using the options described below. When inserting particles above a surface in a non-periodic box (see the \texttt{boundary} command), the possibility of a particle escaping the surface and flying upward should be considered, since the particle may be lost or the box size may grow infinitely large. A \texttt{fix wall/reflect} command can be used to prevent this behavior. Note that if a shrink-wrap boundary is used, it is OK to insert the new particle outside the box, however the box will immediately be expanded to include the new particle. When simulating a sputtering experiment it is probably more realistic to ignore those atoms using the \texttt{thermo Modify} command with the \texttt{lost ignore} option and a fixed \texttt{boundary}.

The fix deposit command must use the \texttt{region} keyword to define an insertion volume. The specified region must have been previously defined with a \texttt{region} command. It must be defined with side = \texttt{in}.

\textbf{Note:} LAMMPS checks that the specified region is wholly inside the simulation box. It can do this correctly for orthonormal simulation boxes. However for triclinic boxes, it only tests against the larger orthonormal box that bounds the tilted simulation box. If the specified region includes volume outside the tilted box, then an insertion will likely fail, leading to a “lost atoms” error. Thus for triclinic boxes you should insure the specified region is wholly inside the simulation box.

The locations of inserted particles are taken from uniform distributed random numbers, unless the \texttt{gaussian} keyword is used. Then the individual coordinates are taken from a gaussian distribution of width \texttt{sigma} centered on \texttt{xmid,ymid,zmid}.

Individual atoms are inserted, unless the \texttt{mol} keyword is used. It specifies a \texttt{template-ID} previously defined using the \texttt{molecule} command, which reads files that define one or more molecules. The coordinates, atom types, charges, etc, as well as any bond/angle/etc and special neighbor information for the molecule can be specified in the molecule file. See the \texttt{molecule} command for details. The only settings required to be in each file are the coordinates and types of atoms in the molecule.

If the molecule template contains more than one molecule, the relative probability of depositing each molecule can be specified by the \texttt{molfrac} keyword. \( N \) relative probabilities, each from 0.0 to 1.0, are specified, where \( N \) is the number of molecules in the template. Each time a molecule is deposited, a random number is used to sample from the list of relative probabilities. The \( N \) values must sum to 1.0.

If you wish to insert molecules via the \texttt{mol} keyword, that will be treated as rigid bodies, use the \texttt{rigid} keyword, specifying as its value the ID of a separate \texttt{fix rigid/small} command which also appears in your input script.

\textbf{Note:} If you wish the new rigid molecules (and other rigid molecules) to be thermostatted correctly via \texttt{fix rigid/small/nvt} or \texttt{fix rigid/small/npt}, then you need to use the “fix_modify dynamic/dof yes” command for the rigid
This is to inform that fix that the molecule count will vary dynamically.

If you wish to insert molecules via the mol keyword, that will have their bonds or angles constrained via SHAKE, use the shake keyword, specifying as its value the ID of a separate fix shake command which also appears in your input script.

Each timestep a particle is inserted, the coordinates for its atoms are chosen as follows. For insertion of individual atoms, the “position” referred to in the following description is the coordinate of the atom. For insertion of molecule, the “position” is the geometric center of the molecule; see the molecule doc page for details. A random rotation of the molecule around its center point is performed, which determines the coordinates all the individual atoms.

A random position within the region insertion volume is generated. If neither the global or local keyword is used, the random position is the trial position. If the global keyword is used, the random x,y values are used, but the z position of the new particle is set above the highest current atom in the simulation by a distance randomly chosen between lo/hi. (For a 2d simulation, this is done for the y position.) If the local keyword is used, the z position is set a distance between lo/hi above the highest current atom in the simulation that is “nearby” the chosen x,y position. In this context, “nearby” means the lateral distance (in x,y) between the new and old particles is less than the delta setting.

Once a trial x,y,z position has been selected, the insertion is only performed if no current atom in the simulation is within a distance R of any atom in the new particle, including the effect of periodic boundary conditions if applicable. R is defined by the near keyword. Note that the default value for R is 0.0, which will allow atoms to strongly overlap if you are inserting where other atoms are present. This distance test is performed independently for each atom in an inserted molecule, based on the randomly rotated configuration of the molecule. If this test fails, a new random position within the insertion volume is chosen and another trial is made. Up to Q attempts are made. If the particle is not successfully inserted, LAMMPS prints a warning message.

Note: If you are inserting finite size particles or a molecule or rigid body consisting of finite-size particles, then you should typically set R larger than the distance at which any inserted particle may overlap with either a previously inserted particle or an existing particle. LAMMPS will issue a warning if R is smaller than this value, based on the radii of existing and inserted particles.

The rate option moves the insertion volume in the z direction (3d) or y direction (2d). This enables particles to be inserted from a successively higher height over time. Note that this parameter is ignored if the global or local keywords are used, since those options choose a z-coordinate for insertion independently.

The vx, vy, and vz components of velocity for the inserted particle are set using the values specified for the vx, vy, and vz keywords. Note that normally, new particles should be assigned a negative vertical velocity so that they move towards the surface. For molecules, the same velocity is given to every particle (no rotation or bond vibration).

If the target option is used, the velocity vector of the inserted particle is changed so that it points from the insertion position towards the specified target point. The magnitude of the velocity is unchanged. This can be useful, for example, for simulating a sputtering process. E.g. the target point can be far away, so that all incident particles strike the surface as if they are in an incident beam of particles at a prescribed angle.

The orient keyword is only used when molecules are deposited. By default, each molecule is inserted at a random orientation. If this keyword is specified, then (rx,ry,rz) is used as an orientation vector, and each inserted molecule is rotated around that vector with a random value from zero to 2*PI. For a 2d simulation, rx = ry = 0.0 is required, since rotations can only be performed around the z axis.

The id keyword determines how atom IDs and molecule IDs are assigned to newly deposited particles. Molecule IDs are only assigned if molecules are being inserted. For the max setting, the atom and molecule IDs of all current atoms are checked. Atoms in the new particle are assigned IDs starting with the current maximum plus one. If a molecule is inserted it is assigned an ID = current maximum plus one. This means that if particles leave the system, the new IDs may replace the lost ones. For the next setting, the maximum ID of any atom and molecule is stored at the time the fix is defined. Each time a new particle is added, this value is incremented to assign IDs to the new atom(s) or molecule. Thus atom and molecule IDs for deposited particles will be consecutive even if particles leave the system over time.
The *units* keyword determines the meaning of the distance units used for the other deposition parameters. A *box* value selects standard distance units as defined by the *units* command, e.g. Angstroms for units = real or metal. A *lattice* value means the distance units are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacing. Note that the units choice affects all the keyword values that have units of distance or velocity.

**Note:** If you are monitoring the temperature of a system where the atom count is changing due to adding particles, you typically should use the *compute_modify* dynamic yes command for the temperature compute you are using.

### 17.35.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the deposition to binary restart files. This includes information about how many particles have been deposited, the random number generator seed, the next timestep for deposition, etc. See the *read_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

**Note:** For this to work correctly, the timestep must not be changed after reading the restart with *reset_timestep*. The fix will try to detect it and stop with an error.

None of the *fix_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during energy minimization.

### 17.35.5 Restrictions

The specified insertion region cannot be a “dynamic” region, as defined by the *region* command.

### 17.35.6 Related commands

*fix pour, region*

### 17.35.7 Default

Insertions are performed for individual atoms, i.e. no *mol* setting is defined. If the *mol* keyword is used, the default for *molfrac* is an equal probabilities for all molecules in the template. Additional option defaults are *id* = max, *delta* = 0.0, *near* = 0.0, *attempt* = 10, *rate* = 0.0, *vx* = 0.0 0.0, *vy* = 0.0 0.0, *vz* = 0.0 0.0, and *units* = lattice.

### 17.36 fix dpd/energy command

Accelerator Variants: *dpd/energy/kk*
17.36.1 Syntax

```plaintext
fix ID group-ID dpd/energy
```

- ID, group-ID are documented in `fix` command
- `dpd/energy` = style name of this `fix` command

17.36.2 Examples

```plaintext
fix 1 all dpd/energy
```

17.36.3 Description

Perform constant energy dissipative particle dynamics (DPD-E) integration. This fix updates the internal energies for particles in the group at each timestep. It must be used in conjunction with a deterministic integrator (e.g. `fix nve`) that updates the particle positions and velocities.

For `fix dpd/energy`, the particle internal temperature is related to the particle internal energy through a mesoparticle equation of state. An additional fix must be specified that defines the equation of state for each particle, e.g. `fix eos/cv`.

This fix must be used with the `pair_style dpd/fdt/energy` command.

Note that numerous variants of DPD can be specified by choosing an appropriate combination of the integrator and `pair_style dpd/fdt/energy` command. DPD under isoenergetic conditions can be specified by using `fix dpd/energy`, `fix nve` and `pair_style dpd/fdt/energy`. DPD under isoenthalpic conditions can be specified by using `fix dpd/energy`, `fix nph` and `pair_style dpd/fdt/energy`. Examples of each DPD variant are provided in the examples/PACKAGES/dpd-react directory.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

17.36.4 Restrictions

This command is part of the DPD-REACT package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This fix must be used with an additional fix that specifies time integration, e.g. `fix nve`.

The fix `dpd/energy` requires the `dpd atom_style` to be used in order to properly account for the particle internal energies and temperature.

The fix `dpd/energy` must be used with an additional fix that specifies the mesoparticle equation of state for each particle.

17.38 fix tdpd/source command

17.38.1 Syntax

\[
\text{fix ID group-ID edpd/source keyword values } ... \\
\text{fix ID group-ID tdpd/source cc_index keyword values } ...
\]

- ID, group-ID are documented in fix command
- edpd/source or tdpd/source = style name of this fix command
- index (only specified for tdpd/source) = index of chemical species (1 to Nspecies)
- keyword = sphere or cuboid

sphere values = cx, cy, cz, radius, source
- cx, cy, cz = x, y, z center of spherical domain (distance units)
- radius = radius of a spherical domain (distance units)
- source = heat source or concentration source (flux units, see below)

cuboid values = cx, cy, cz, dLx, dLy, dLz, source
- cx, cy, cz = x, y, z lower left corner of a cuboid domain (distance units)
- dLx, dLy, dLz = x, y, z side length of a cuboid domain (distance units)
- source = heat source or concentration source (flux units, see below)

17.38.2 Examples

\[
\begin{align*}
\text{fix 1 all edpd/source sphere} & \quad 0.0 \quad 0.0 \quad 0.0 \quad 5.0 \quad 0.01 \\

\text{fix 1 all tdpd/source 2 cuboid} & \quad 0.0 \quad 0.0 \quad 0.0 \quad 20.0 \quad 10.0 \quad 10.0 \quad 0.01
\end{align*}
\]
17.38.3 Description

Fix edpd/source adds a heat source as an external heat flux to each atom in a spherical or cuboid domain, where the source is in units of energy/time. Fix tdpd/source adds an external concentration source of the chemical species specified by index as an external concentration flux for each atom in a spherical or cuboid domain, where the source is in units of mole/volume/time.

This command can be used to give an additional heat/concentration source term to atoms in a simulation, such as for a simulation of a heat conduction with a source term (see Fig.12 in (Li2014)) or diffusion with a source term (see Fig.1 in (Li2015)), as an analog of a periodic Poiseuille flow problem.

If the sphere keyword is used, the cx,cy,cz,radius defines a spherical domain to apply the source flux to.

If the cuboid keyword is used, the cx,cy,cz,dLx,dLy,dLz defines a cuboid domain to apply the source flux to.

17.38.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.38.5 Restrictions

This fix is part of the DPD-MESO package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

Fix edpd/source must be used with the pair_style edpd command. Fix tdpd/source must be used with the pair_style tdpd command.

17.38.6 Related commands

17.38.7 Default

one

17.39 fix drag command

17.39.1 Syntax

```plaintext
fix ID group-ID drag x y z fmag delta
```

- ID, group-ID are documented in `fix` command
- drag = style name of this fix command
- x, y, z = coord to drag atoms towards
- fmag = magnitude of force to apply to each atom (force units)
- delta = cutoff distance inside of which force is not applied (distance units)

17.39.2 Examples

```plaintext
fix center small-molecule drag 0.0 10.0 0.0 5.0 2.0
```

17.39.3 Description

Apply a force to each atom in a group to drag it towards the point (x, y, z). The magnitude of the force is specified by fmag. If an atom is closer than a distance delta to the point, then the force is not applied.

Any of the x, y, z values can be specified as NULL which means do not include that dimension in the distance calculation or force application.

This command can be used to steer one or more atoms to a new location in the simulation.

17.39.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The `fix_modify respa` option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global 3-vector of forces, which can be accessed by various `output commands`. This is the total force on the group of atoms by the drag force. The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during energy minimization.

17.39.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

17.40 fix drude command

17.40.1 Syntax

fix ID group-ID drude flag1 flag2 ... flagN

- ID, group-ID are documented in fix command
- drude = style name of this fix command
- flag1 flag2 ... flagN = Drude flag for each atom type (1 to N) in the system

17.40.2 Examples

- fix 1 all drude 1 1 0 1 0 2 2 2
- fix 1 all drude C C N C N D D D

Example input scripts available: examples/PACKAGES/drude

17.40.3 Description

Assign each atom type in the system to be one of 3 kinds of atoms within the Drude polarization model. This fix is designed to be used with the thermalized Drude oscillator model. Polarizable models in LAMMPS are described on the Howto polarizable doc page.

The three possible types can be designated with an integer (0,1,2) or capital letter (N,C,D):
- 0 or N = non-polarizable atom (not part of Drude model)
- 1 or C = Drude core
- 2 or D = Drude electron

17.40.4 Restrictions

This fix should be invoked before any other commands that implement the Drude oscillator model, such as fix langevin/drude, fix tgnvt/drude, fix drude/transform, compute temp/drude, pair_style thole.
17.40.5 Related commands

17.41 fix drude/transform/direct command

17.42 fix drude/transform/inverse command

17.42.1 Syntax

```
fix ID group-ID style keyword value ... 
```

- ID, group-ID are documented in *fix* command
- style = *drude/transform/direct* or *drude/transform/inverse*

17.42.2 Examples

```
fix 3 all drude/transform/direct
fix 1 all drude/transform/inverse
```

Example input scripts available: examples/PACKAGES/drude

17.42.3 Description

Transform the coordinates of Drude oscillators from real to reduced and back for thermalizing the Drude oscillators as described in *(Lamoureux)* using a Nose-Hoover thermostat. This fix is designed to be used with the *thermalized Drude oscillator model*. Polarizable models in LAMMPS are described on the *Howto polarizable* doc page.

Drude oscillators are a pair of atoms representing a single polarizable atom. Ideally, the mass of Drude particles would vanish and their positions would be determined self-consistently by iterative minimization of the energy, the cores’ positions being fixed. It is however more efficient and it yields comparable results, if the Drude oscillators (the motion of the Drude particle relative to the core) are thermalized at a low temperature. In that case, the Drude particles need a small mass.

The thermostats act on the reduced degrees of freedom, which are defined by the following equations. Note that in these equations upper case denotes atomic or center of mass values and lower case denotes Drude particle or dipole values. Primes denote the transformed (reduced) values, while bare letters denote the original values.

**Masses:**

\[
M' = M + m \\
\]

\[
m' = \frac{M}{M'} m \\
\]
Positions:
\[ X' = \frac{MX + mx}{M'} \]
\[ x' = x - X \]

Velocities:
\[ V' = \frac{MV + mv}{M'} \]
\[ v' = v - V \]

Forces:
\[ F' = F + f \]
\[ f' = \frac{Mf - mf}{M'} \]

This transform conserves the total kinetic energy
\[ \frac{1}{2} (MV^2 + mv^2) = \frac{1}{2} (M'V'^2 + m'v'^2) \]

and the virial defined with absolute positions
\[ X F + x f = X' F' + x' f' \]

This fix requires each atom know whether it is a Drude particle or not. You must therefore use the `fix drude` command to specify the Drude status of each atom type.

**Note:** only the Drude core atoms need to be in the group specified for this fix. A Drude electron will be transformed together with its core even if it is not itself in the group. It is safe to include Drude electrons or non-polarizable atoms in the group. The non-polarizable atoms will simply not be transformed.

This fix does NOT perform time integration. It only transform masses, coordinates, velocities and forces. Thus you must use separate time integration fixes, like `fix nve` or `fix npt` to actually update the velocities and positions of atoms. In order to thermalize the reduced degrees of freedom at different temperatures, two Nose-Hoover thermostats must be defined, acting on two distinct groups.

**Note:** The `fix drude/transform/direct` command must appear before any Nose-Hoover thermostating fixes. The `fix drude/transform/inverse` command must appear after any Nose-Hoover thermostating fixes.

Example:
```
fix fDIRECT all drude/transform/direct
fix fNVT gCORES nvt temp 300.0 300.0 100
fix fNVT gDRUDES nvt temp 1.0 1.0 100
fix fINVERSE all drude/transform/inverse
compute TDRUDE all temp/drude
```
In this example, \texttt{gCORES} is the group of the atom cores and \texttt{gDRUDES} is the group of the Drude particles (electrons). The centers of mass of the Drude oscillators will be thermostatted at 300.0 and the internal degrees of freedom will be thermostatted at 1.0. The temperatures of cores and Drude particles, in center-of-mass and relative coordinates, are calculated using \texttt{compute temp/drude}.

In addition, if you want to use a barostat to simulate a system at constant pressure, only one of the Nose-Hoover fixes must be \texttt{npt}, the other one should be \texttt{nvt}. You must add a \texttt{compute temp/com} and a \texttt{fix modify} command so that the temperature of the \texttt{npt} fix be just that of its group (the Drude cores) but the pressure be the overall pressure \texttt{thermo_press}.

Example:

\begin{verbatim}
compute cTEMP_CORE gCORES temp/com
fix fDIRECT all drude/transform/direct
fix fNPT gCORES npt temp 298.0 298.0 100 iso 1.0 1.0 500
fix_modify fNPT temp cTEMP_CORE press thermo_press
fix fNVT gDRUDES nvt temp 5.0 5.0 100
fix fINVERSE all drude/transform/inverse
\end{verbatim}

In this example, \texttt{gCORES} is the group of the atom cores and \texttt{gDRUDES} is the group of the Drude particles. The centers of mass of the Drude oscillators will be thermostatted at 298.0 and the internal degrees of freedom will be thermostatted at 5.0. The whole system will be barostatted at 1.0.

In order to avoid the flying ice cube problem (irreversible transfer of linear momentum to the center of mass of the system), you may need to add a \texttt{fix momentum} command:

\begin{verbatim}
fix fMOMENTUM all momentum 100 linear 1 1 1
\end{verbatim}

\section*{17.42.4 Restart, \texttt{fix modify}, output, run start/stop, minimize info}

17.43  fix dt/reset command

17.43.1  Syntax

`fix ID group-ID dt/reset N Tmin Tmax Xmax keyword values ...`

- ID, group-ID are documented in `fix` command
- dt/reset = style name of this fix command
- N = re-compute dt every N timesteps
- Tmin = minimum dt allowed which can be NULL (time units)
- Tmax = maximum dt allowed which can be NULL (time units)
- Xmax = maximum distance for an atom to move in one timestep (distance units)
- zero or more keyword/value pairs may be appended
- keyword = `emax` or `units`

`emax` value = Emax
Emax = maximum kinetic energy change for an atom in one timestep (energy units)
`units` value = `lattice` or `box`
  `lattice` = Xmax is defined in lattice units
  `box` = Xmax is defined in simulation box units

17.43.2  Examples

```plaintext
fix 5 all dt/reset 10 1.0e-5 0.01 0.1
fix 5 all dt/reset 10 0.01 2.0 0.2 units box
fix 5 all dt/reset 5 NULL 0.001 0.5 emax 30 units box
```

17.43.3  Description

Reset the timestep size every N steps during a run, so that no atom moves further than the specified Xmax distance, based on current atom velocities and forces. Optionally an additional criterion is imposed by the `emax` keyword, so that no atom’s kinetic energy changes by more than the specified Emax.

This can be useful when starting from a configuration with overlapping atoms, where forces will be large. Or it can be useful when running an impact simulation where one or more high-energy atoms collide with a solid, causing a damage cascade.

This fix overrides the timestep size setting made by the `timestep` command. The new timestep size dt is computed in the following manner.

For each atom, the timestep is computed that would cause it to displace Xmax on the next integration step, as a function of its current velocity and force. Since performing this calculation exactly would require the solution to a quartic equation, a cheaper estimate is generated. The estimate is conservative in that the atom’s displacement is guaranteed not to exceed Xmax, though it may be smaller.

In addition if the `emax` keyword is used, the specified Emax value is enforced as a limit on how much an atom’s kinetic energy can change. If the timestep required is even smaller than for the Xmax displacement, then the smaller timestep is used.
Given this putative timestep for each atom, the minimum timestep value across all atoms is computed. Then the $T_{min}$ and $T_{max}$ bounds are applied, if specified. If one (or both) is specified as NULL, it is not applied.

When the run style is respa, this fix resets the outer loop (largest) timestep, which is the same timestep that the timestep command sets.

Note that the cumulative simulation time (in time units), which accounts for changes in the timestep size as a simulation proceeds, can be accessed by the thermo_style time keyword.

Also note that the dump_modify every/time option allows dump files to be written at intervals specified by simulation time, rather than by timesteps. Simulation time is in time units; see the units doc page for details.

**17.43.4 Restart, fix_modify, output, run start/stop, minimize info**

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. This fix computes a global scalar which can be accessed by various output commands. The scalar stores the last timestep on which the timestep was reset to a new value.

The scalar value calculated by this fix is “intensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

**17.43.5 Restrictions**

none

**17.43.6 Related commands**

$timestep$, $dump_modify$ every/time

**17.43.7 Default**

The option defaults are units = lattice, and no emax kinetic energy limit.

**17.44 fix efield command**

**17.44.1 Syntax**

Fix ID group-ID efield ex ey ez keyword value ...

- ID, group-ID are documented in fix command
- efield = style name of this fix command
- ex,ey,ez = E-field component values (electric field units)
- any of ex,ey,ez can be a variable (see below)
- zero or more keyword/value pairs may be appended to args
- keyword = region or energy
region value = region-ID
    region-ID = ID of region atoms must be in to have added force
energy value = v_name
    v_name = variable with name that calculates the potential energy of each atom in the added E-field

17.44.2 Examples

```plaintext
fix kick external-field efield 1.0 0.0 0.0
fix kick external-field efield 0.0 0.0 v_oscillate
```

17.44.3 Description

Add a force \( F = qE \) to each charged atom in the group due to an external electric field being applied to the system. If the system contains point-dipoles, also add a torque on the dipoles due to the external electric field.

For charges, any of the 3 quantities defining the E-field components can be specified as an equal-style or atom-style variable, namely \( ex, ey, ez \). If the value is a variable, it should be specified as \( v_name \), where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the E-field component.

For point-dipoles, equal-style variables can be used, but atom-style variables are not currently supported, since they imply a spatial gradient in the electric field which means additional terms with gradients of the field are required for the force and torque on dipoles.

Equal-style variables can specify formulas with various mathematical functions, and include `thermo_style` command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent E-field.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus it is easy to specify a spatially-dependent E-field with optional time-dependence as well.

If the `region` keyword is used, the atom must also be in the specified geometric region in order to have force added to it.

Adding a force or torque to atoms implies a change in their potential energy as they move or rotate due to the applied E-field.

For dynamics via the “run” command, this energy can be optionally added to the system’s potential energy for thermo-dynamic output (see below). For energy minimization via the “minimize” command, this energy must be added to the system’s potential energy to formulate a self-consistent minimization problem (see below).

The `energy` keyword is not allowed if the added field is a constant vector \((ex,ey,ez)\), with all components defined as numeric constants and not as variables. This is because LAMMPS can compute the energy for each charged particle directly as \( E = -x \cdot qE = -q(x*ex + y*ey + z*ez) \), so that \(-\text{Grad}(E) = F\). Similarly for point-dipole particles the energy can be computed as \( E = -\mu \cdot E = -(\mu x*ex + \mu y*ey + \mu z*ez)\).

The `energy` keyword is optional if the added force is defined with one or more variables, and if you are performing dynamics via the `run` command. If the keyword is not used, LAMMPS will set the energy to 0.0, which is typically fine for dynamics.

The `energy` keyword is required if the added force is defined with one or more variables, and you are performing energy minimization via the “minimize” command for charged particles. It is not required for point-dipoles, but a warning is issued since the minimizer in LAMMPS does not rotate dipoles, so you should not expect to be able to minimize the orientation of dipoles in an applied electric field.
The **energy** keyword specifies the name of an atom-style variable which is used to compute the energy of each atom as function of its position. Like variables used for \(ex\), \(ey\), \(ez\), the energy variable is specified as \(v\_name\), where name is the variable name.

Note that when the **energy** keyword is used during an energy minimization, you must insure that the formula defined for the atom-style variable is consistent with the force variable formulas, i.e. that \(-\text{Grad}(E) = F\). For example, if the force due to the electric field were a spring-like \(F = kx\), then the energy formula should be \(E = -0.5kx^2\). If you don’t do this correctly, the minimization will not converge properly.

### 17.44.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The **fix_modify energy** option is supported by this fix to add the potential energy inferred by the added force due to the electric field to the global potential energy of the system as part of thermodynamic output. The default setting for this fix is **fix_modify energy no**. Note that this energy is a fictitious quantity but is needed so that the **minimize** command can include the forces added by this fix in a consistent manner. I.e. there is a decrease in potential energy when atoms move in the direction of the added force due to the electric field.

The **fix_modify virial** option is supported by this fix to add the contribution due to the added forces on atoms to both the global pressure and per-atom stress of the system via the **compute pressure** and **compute stress/atom** commands. The former can be accessed by thermodynamic output. The default setting for this fix is **fix_modify virial no**.

The **fix_modify respa** option is supported by this fix. This allows to set at which level of the \(r\)-RESPA integrator the fix adding its forces. Default is the outermost level.

This fix computes a global scalar and a global 3-vector of forces, which can be accessed by various output commands. The scalar is the potential energy discussed above. The vector is the total force added to the group of atoms. The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the **start/stop** keywords of the **run** command.

The forces due to this fix are imposed during an energy minimization, invoked by the **minimize** command. You should not specify force components with a variable that has time-dependence for use with a minimizer, since the minimizer increments the timestep as the iteration count during the minimization.

**Note:** If you want the fictitious potential energy associated with the added forces to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the **fix_modify energy** option for this fix.

(continues on next page)
17.45.3 Description

This fix implements the asymmetric version of the enhanced heat exchange algorithm \((Wirnsberger)\). The eHEX algorithm is an extension of the heat exchange algorithm \((Ikeshoji)\) and adds an additional coordinate integration to account for higher-order truncation terms in the operator splitting. The original HEX algorithm (implemented as fix heat) is known to exhibit a slight energy drift limiting the accessible simulation times to a few nanoseconds. This issue is greatly improved by the new algorithm decreasing the energy drift by at least a factor of a hundred (LJ and SPC/E water) with little computational overhead.

In both algorithms (non-translational) kinetic energy is constantly swapped between regions (reservoirs) to impose a heat flux onto the system. The equations of motion are therefore modified if a particle \(i\) is located inside a reservoir \(\Gamma_k\) where \(k > 0\). We use \(\Gamma_0\) to label those parts of the simulation box which are not thermostatted.) The input parameter \(\text{region-ID}\) of this fix corresponds to \(k\). The energy swap is modelled by introducing an additional thermostating force to the equations of motion, such that the time evolution of coordinates and momenta of particle \(i\) becomes \((Wirnsberger)\)

\[
\dot{r}_i = v_i, \\
\dot{v}_i = \frac{f_i}{m_i} + \frac{g_i}{m_i}.
\]

The thermostating force is given by

\[
g_i = \begin{cases} 
\frac{m_i}{2} \frac{F_{\Gamma_k(r_i)}}{r_{\Gamma_k(r_i)}} (v_i - v_{\Gamma_k(r_i)}) & k(r_i) > 0 \ (\text{inside a reservoir}), \\
0 & \text{otherwise},
\end{cases}
\]

where \(m_i\) is the mass and \(k(r_i)\) maps the particle position to the respective reservoir. The quantity \(F_{\Gamma_k(r_i)}\) corresponds to the input parameter \(F\), which is the energy flux into the reservoir. Furthermore, \(r_{\Gamma_k(r_i)}\) and \(v_{\Gamma_k(r_i)}\) denote the non-translational kinetic energy and the center of mass velocity of that reservoir. The thermostating force does not affect the center of mass velocities of the individual reservoirs and the entire simulation box. A derivation of the equations and details on the numerical implementation with velocity Verlet in LAMMPS can be found in reference “(Wirnsberger)”\(^\text{#_Wirnsberger}\).

**Note:** This fix only integrates the thermostating force and must be combined with another integrator, such as fix nve, to solve the full equations of motion.

This fix is different from a thermostat such as fix nvt or fix temp/rescale in that energy is added/subtracted continuously. Thus if there is not another mechanism in place to counterbalance this effect, the entire system will heat or cool continuously.

**Note:** If heat is subtracted from the system too aggressively so that the group’s kinetic energy would go to zero, then LAMMPS will halt with an error message. Increasing the value of nevery means that heat is added/subtracted less frequently but in larger portions. The resulting temperature profile will therefore be the same.

This fix will default to fix heat (HEX algorithm) if the keyword \(hex\) is specified.

**Compatibility with SHAKE and RATTLE (rigid molecules):**
This fix is compatible with `fix shake` and `fix rattle`. If either of these constraining algorithms is specified in the input script and the keyword `constrain` is set, the bond distances will be corrected a second time at the end of the integration step. It is recommended to specify the keyword `com` in addition to the keyword `constrain`. With this option all sites of a constrained cluster are rescaled, if its center of mass is located inside the region. Rescaling all sites of a cluster by the same factor does not introduce any velocity components along fixed bonds. No rescaling takes place if the center of mass lies outside the region.

**Note:** You can only use the keyword `com` along with `constrain`.

To achieve the highest accuracy it is recommended to use `fix rattle` with the keywords `constrain` and `com` as shown in the second example. Only if RATTLE is employed, the velocity constraints will be satisfied.

**Note:** Even if RATTLE is used and the keywords `com` and `constrain` are both set, the coordinate constraints will not necessarily be satisfied up to the target precision. The velocity constraints are satisfied as long as all sites of a cluster are rescaled (keyword `com`) and the cluster does not span adjacent reservoirs. The current implementation of the eHEX algorithm introduces a small error in the bond distances, which goes to zero with order three in the timestep. For example, in a simulation of SPC/E water with a timestep of 2 fs the maximum relative error in the bond distances was found to be on the order of $10^{-7}$ for relatively large temperature gradients. A higher precision can be achieved by decreasing the timestep.

### 17.45.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

### 17.45.5 Restrictions

This fix is part of the RIGID package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

### 17.45.6 Related commands

17.48.2 Examples

```c
fix fxcomp bot electrode/comp -1.0 1.805 couple top 1.0 couple ref 0.0 write_inv inv.csv
-symm on
fix fxcomp electrodes electrode/conq 0.0 1.805
fix fxcomp bot electrode/thermo -1.0 1.805 temp 298 100 couple top 1.0
```

17.48.3 Description

The `fix electrode/comp` mode implements a constant potential method (CPM) \((\text{Siepmann, Reed})\). Charges of groups specified via group-ID and optionally with the `couple` keyword are adapted to meet their respective potential at every time step. An arbitrary number of electrodes can be set but the respective groups may not overlap. Electrode charges have a Gaussian charge distribution with reciprocal width \(\eta\). The energy minimization is achieved via matrix inversion \((\text{Wang})\).

The `fix electrode/conq` enforces a total charge specified in the input on each electrode. The energy is minimized w.r.t. the charge distribution within the electrode.

The `fix electrode/thermo` implements a thermo-potentiostat \((\text{Deissenbeck})\). Temperature and time constant of the thermo-potentiostat need to be specified using the `temp` keyword. Currently, only two electrodes are possible with this style. This fix necessitates the use of a long range solver that calculates and provides the matrix of electrode-electrode interactions and a vector of electrode-electrolyte interactions. The Kspace styles `ewald/electrode`, `pppm/electrode` and `pppm/electrode/intel` are created specifically for this task \((\text{Ahrens-Iwers})\).

For systems with non-periodic boundaries in one or two directions dipole corrections are available with the `kspace_modify`. For ewald/electrode a two-dimensional Ewald summation \((\text{Hu})\) can be used by setting “slab ew2d”:

```c
kspace_modify slab <slab_factor>
kspace_modify wire <wire_factor>
kspace_modify slab ew2d
```

Two implementations for the calculation of the elastance matrix are available with pppm and can be selected using the `amat onestep/twostep` keyword. `onestep` is the default; `twostep` can be faster for large electrodes and a moderate mesh size but requires more memory.

```c
kspace_modify amat onestep/twostep
```

The `fix_modify tf` option enables the Thomas-Fermi metallicity model \((\text{Scalfi})\) and allows parameters to be set for each atom type.

```c
fix_modify ID tf type length voronoi
```

If this option is used parameters must be set for all atom types of the electrode.

The `fix_modify timer` option turns on (off) additional timer outputs in the log file, for code developers to track optimization.

```c
fix_modify ID timer on/off
```

The `fix_modify set` options allow calculated quantities to be accessed via internal variables. Currently four types of quantities can be accessed:

```c
fix-modify ID set v group-ID variablename
fix-modify ID set qsb group-ID variablename
```

(continues on next page)
One use case is to output the potential that is internally calculated and applied to each electrode group by `fix electrode/conq` or `fix electrode/thermo`. For that case the `v` option makes `fix electrode` update the variable `variablename` with the potential applied to group `group-ID`, where `group-ID` must be a group whose charges are updated by `fix electrode` and `variablename` must be an internal-style variable:

```
fix conq bot electrode/conq -1.0 1.979 couple top 1.0
variable vbot internal 0.0
fix_modify conq set v bot vbot
```

The `qsb` option similarly outputs the total updated charge of the group if its potential were 0.0V. The `mc` option requires two `group-IDs`, and outputs the entry `{group-ID1, group-ID2}` of the (symmetric) macro-capacitance matrix (MC) which relates the electrodes’ applied potentials (V), total charges (Q), and total charges at 0.0 V (Qsb):

\[ Q = Q_{SB} + MC \cdot V \]

Lastly, the `me` option also requires two `group-IDs` and outputs the entry `{group-ID1, group-ID2}` of the macro-elastance matrix, which is the inverse of the macro-capacitance matrix. (As the names denote, the macro-capacitance matrix gives electrode charges from potentials, and the macro-elastance matrix gives electrode potentials from charges).

**Warning:** Positions of electrode particles have to be immobilized at all times.

The parallelization for the fix works best if electrode atoms are evenly distributed across processors. For a system with two electrodes at the bottom and top of the cell this can be achieved with `processors * * 2`, or with the line

```
if "$(extract_setting(world_size) % 2) == 0" then "processors * * 2"
```

which avoids an error if the script is run on an odd number of processors (such as on just one processor for testing).

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

fix 1 all electron/stopping/fit 4.63 3.3e-3 4.0e-8
fix 1 all electron/stopping/fit 3.49 1.8e-3 9.0e-8 7.57 4.2e-3 5.0e-8
```

17.50.3 Description

This fix implements inelastic energy loss for fast projectiles in solids. It applies a friction force to fast moving atoms to slow them down due to electronic stopping (energy lost via electronic collisions per unit of distance). This fix should be used for simulation of irradiation damage or ion implantation, where the ions can lose noticeable amounts of energy from electron excitations. If the electronic stopping power is not considered, the simulated range of the ions can be severely overestimated ([Nordlund98], [Nordlund95]).

The electronic stopping is implemented by applying a friction force to each atom as:

\[ \vec{F}_i = \vec{F}^{\text{p}}_i - \frac{\vec{v}_i}{\|\vec{v}_i\|} \cdot S_e \]
where $\vec{F}_i$ is the resulting total force on the atom, $\vec{F}_i^0$ is the original force applied to the atom, $\vec{v}_i$ is its velocity and $S_e$ is the stopping power of the ion.

**Note:** In addition to electronic stopping, atomic cascades and irradiation simulations require the use of an adaptive timestep (see `fix dt/reset`) and the repulsive ZBL potential (see `ZBL` potential) or similar. Without these settings the interaction between the ion and the target atoms will be faulty. It is also common to use in such simulations a thermostat (`fix_nvt`) in the borders of the simulation cell.

**Note:** In addition to electronic stopping, atomic cascades and irradiation simulations require the use of an adaptive timestep (see `fix dt/reset`) and the repulsive ZBL potential (see `ZBL` potential) or similar. Without these settings the interaction between the ion and the target atoms will be faulty. It is also common to use in such simulations a thermostat (`fix_nvt`) in the borders of the simulation cell.

At low velocities the electronic stopping is negligible. The electronic friction is not applied to atoms whose kinetic energy is smaller than $E_{cut}$, or smaller than the lowest energy value given in the table in file. Electronic stopping should be applied only when a projectile reaches bulk material. This fix scans neighbor list and excludes atoms with fewer than `minneigh` neighbors (by default one). If the pair potential cutoff is large, `minneigh` should be increased, though not above the number of nearest neighbors in bulk material. An alternative is to disable the check for neighbors by setting `minneigh` to zero and using the `region` keyword. This is necessary when running simulations of cluster bombardment.

If the `region` keyword is used, the atom must also be in the specified geometric `region` in order to have electronic stopping applied to it. This is useful if the position of the bulk material is fixed. By default the electronic stopping is applied everywhere in the simulation cell.

The energy ranges and stopping powers are read from the file `file`. Lines starting with `#` and empty lines are ignored. Otherwise each line must contain exactly $N+1$ numbers, where $N$ is the number of atom types in the simulation.

The first column is the energy for which the stopping powers on that line apply. The energies must be sorted from the smallest to the largest. The other columns are the stopping powers $S_e$ for each atom type, in ascending order, in force units. The stopping powers for intermediate energy values are calculated with linear interpolation between 2 nearest points.

For example:

```
# This is a comment
# atom-1 atom-2
# eV eV/Ang eV/Ang # units metal
10 0 0 #
250 60 80 #
750 100 150 #
```

If an atom which would have electronic stopping applied to it has a kinetic energy higher than the largest energy given in `file`, LAMMPS will exit with an error message.

The stopping power depends on the energy of the ion and the target material. The electronic stopping table can be obtained from scientific publications, experimental databases or by using `SRIM` software. Other programs such as `CasP` or `PASS` can calculate the energy deposited as a function of the impact parameter of the ion; these results can be used to derive the stopping power.

Style `electron/stopping/fit` calculates the electronic stopping power and cumulative energy lost to the electron gas via a quadratic functional and applies a drag force to the classical equations-of-motion for all atoms moving above some energy.
minimum cutoff velocity (i.e., kinetic energy). These coefficients can be determined by fitting a quadratic polynomial to electronic stopping data predicted by, for example, SRIM or TD-DFT. Multiple ‘Ecut c1 c2’ values can be provided for multi-species simulations in the order of the atom types. There is an examples/PACKAGES/electron_stopping/directory, which illustrates uses of this command. Details of this implementation are further described in Stewart2018 and Lee2020.

17.50.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.
The fix_modify options are not supported.
This fix computes a global scalar, which can be accessed by various output commands. The scalar is the total energy loss from electronic stopping applied by this fix since the start of the latest run. It is considered “intensive”.
The start/stop keywords of the run command have no effect on this fix.

17.50.5 Restrictions

This pair style is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

17.50.6 Default

The default is no limitation by region, and minneigh = 1.

17.52 fix eos/cv command

17.52.1 Syntax

```
fix ID group-ID eos/cv cv
```

- ID, group-ID are documented in fix command
- eos/cv = style name of this fix command
- cv = constant-volume heat capacity (energy/temperature units)

17.52.2 Examples

```
fix 1 all eos/cv 0.01
```

17.52.3 Description

Fix *eos/cv* applies a mesoparticle equation of state to relate the particle internal energy \( u_i \) to the particle internal temperature \( \theta_i \). The *eos/cv* mesoparticle equation of state requires the constant-volume heat capacity, and is defined as follows:

\[
u_i = u_i^{mech} + u_i^{cond} = C_V \theta_i
\]

where \( C_V \) is the constant-volume heat capacity, \( u^{cond} \) is the internal conductive energy, and \( u^{mech} \) is the internal mechanical energy. Note that alternative definitions of the mesoparticle equation of state are possible.

17.52.4 Restrictions

This command is part of the DPD-REACT package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This command also requires use of the *atom_style dpd* command.
17.52.5 Related commands

`fix shardlow, pair dpd/fdt`

17.52.6 Default

17.53 fix eos/table command

17.53.1 Syntax

| fix ID group-ID eos/table style file N keyword |

- ID, group-ID are documented in `fix` command
- `eos/table` = style name of this fix command
- `style = linear` = method of interpolation
- `file` = filename containing the tabulated equation of state
- `N` = use N values in `linear` tables
- `keyword` = name of table keyword corresponding to table file

17.53.2 Examples

```
fix 1 all eos/table linear eos.table 100000 KEYWORD
```

17.53.3 Description

Fix `eos/table` applies a tabulated mesoparticle equation of state to relate the particle internal energy \( u_i \) to the particle internal temperature \( \text{dpdTheta}_i \).

Fix `eos/table` creates interpolation tables of length \( N \) from internal energy values listed in a file as a function of internal temperature.

The interpolation tables are created by fitting cubic splines to the file values and interpolating energy values at each of \( N \) internal temperatures, and vice versa. During a simulation, these tables are used to interpolate internal energy or temperature values as needed. The interpolation is done with the `linear` style.

For the `linear` style, the internal temperature is used to find 2 surrounding table values from which an internal energy is computed by linear interpolation, and vice versa.

The filename specifies a file containing tabulated internal temperature and internal energy values. The keyword specifies a section of the file. The format of this file is described below.
The format of a tabulated file is as follows (without the parenthesized comments):

<table>
<thead>
<tr>
<th># EOS TABLE</th>
<th>(one or more comment or blank lines)</th>
</tr>
</thead>
<tbody>
<tr>
<td>KEYWORD</td>
<td>(keyword is first text on line)</td>
</tr>
<tr>
<td>N 500</td>
<td>(N parameter)</td>
</tr>
<tr>
<td>1 1.00 0.000</td>
<td>(blank)</td>
</tr>
<tr>
<td>2 1.02 0.001</td>
<td>(index, internal temperature, internal energy)</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
<tr>
<td>500 10.0 0.500</td>
<td></td>
</tr>
</tbody>
</table>

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the fix command.

The next line lists the number of table entries. The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the N specified in the fix eos/table command. Let Ntable = N in the fix command, and Nfile = “N” in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the Nfile tabulated values as nodal points. It uses these to interpolate as needed to generate energy and temperature values at Ntable different points. The resulting tables of length Ntable are then used as described above, when computing energy and temperature relationships. This means that if you want the interpolation tables of length Ntable to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set Ntable = Nfile.

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is the internal temperature (in temperature units), the third value is the internal energy (in energy units).

Note that the internal temperature and internal energy values must increase from one line to the next.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

17.53.4 Restrictions

This command is part of the DPD-REACT package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This command also requires use of the atom_style dpd command.

The equation of state must be a monotonically increasing function.

An error will occur if the internal temperature or internal energies are not within the table cutoffs.

17.53.5 Related commands

fix shardlow, pair dpd/fidt

17.54 fix eos/table/rx command

Accelerator Variants: eos/table/rx/kk

17.54.1 Syntax

```
fix ID group-ID eos/table/rx style file1 N keyword ...
```

- ID, group-ID are documented in fix command
- eos/table/rx = style name of this fix command
- style = linear = method of interpolation
- file1 = filename containing the tabulated equation of state
- N = use N values in linear tables
- keyword = name of table keyword corresponding to table file
- file2 = filename containing the heats of formation of each species (optional)
- deltaHf = heat of formation for a single species in energy units (optional)
- energyCorr = energy correction in energy units (optional)
- tempCorrCoeff = temperature correction coefficient (optional)

17.54.2 Examples

```
fix 1 all eos/table/rx linear eos.table 10000 KEYWORD thermo.table
fix 1 all eos/table/rx linear eos.table 10000 KEYWORD 1.5
fix 1 all eos/table/rx linear eos.table 10000 KEYWORD 1.5 0.025 0.0
```

17.54.3 Description

Fix eos/table/rx applies a tabulated mesoparticle equation of state to relate the concentration-dependent particle internal energy ($u_i$) to the particle internal temperature ($\theta_i$).

The concentration-dependent particle internal energy ($u_i$) is computed according to the following relation:

$$U_i = \sum_{j=1}^{m} c_{i,j}(u_j + \Delta H_{f,j}) + \frac{3k_bT}{2} + Nk_bT$$

where $m$ is the number of species, $c_{i,j}$ is the concentration of species $j$ in particle $i$, $u_j$ is the internal energy of species $j$, $\Delta H_{f,j}$ is the heat of formation of species $j$, $N$ is the number of molecules represented by the coarse-grained particle, $k_b$ is the Boltzmann constant, and $T$ is the temperature of the system. Additionally, it is possible to modify the concentration-dependent particle internal energy relation by adding an energy correction, temperature-dependent correction, and/or a molecule-dependent correction. An energy correction can be specified as a constant
(in energy units). A temperature correction can be specified by multiplying a temperature correction coefficient by the internal temperature. A molecular correction can be specified by multiplying a molecule correction coefficient by the average number of product gas particles in the coarse-grain particle.

Fix **eos/table/rx** creates interpolation tables of length $N$ from $m$ internal energy values of each species $u_j$ listed in a file as a function of internal temperature. During a simulation, these tables are used to interpolate internal energy or temperature values as needed. The interpolation is done with the **linear** style. For the **linear** style, the internal temperature is used to find 2 surrounding table values from which an internal energy is computed by linear interpolation. A secant solver is used to determine the internal temperature from the internal energy.

The first filename specifies a file containing tabulated internal temperature and $m$ internal energy values for each species $u_j$. The keyword specifies a section of the file. The format of this file is described below.

The second filename specifies a file containing heat of formation $\Delta H_{f,j}$ for each species.

In cases where the coarse-grain particle represents a single molecular species (i.e., no reactions occur and fix **rx** is not present in the input file), fix **eos/table/rx** can be applied in a similar manner to fix **eos/table** within a non-reactive DPD simulation. In this case, the heat of formation filename is replaced with the heat of formation value for the single species. Additionally, the energy correction and temperature correction coefficients may also be specified as fix arguments.

The format of a tabulated file is as follows (without the parenthesized comments):

```
# EOS TABLE (one or more comment or blank lines)
KEYWORD (keyword is first text on line)
N 500 h2 no2 n2 ... no (N parameter species1 species2 ... speciesN)
  1 1.00 0.000 ... 0.0000 (index, internal temperature, internal energy of species 1, .....
  2 1.02 0.001 ... 0.0002
  ...
500 10.0 0.500 ... 1.000
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the fix command.

The next line lists the number of table entries and the species names that correspond with all the species listed in the reaction equations through the fix **rx** command. The parameter “N” is required and its value is the number of table entries that follow. Let $N_{file} = \text{"N"}$ in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the $N_{file}$ tabulated values as nodal points.

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is the internal temperature (in temperature units), the third value until the $m+3$ value are the internal energies of the m species (in energy units).

Note that all internal temperature and internal energy values must increase from one line to the next.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

The format of a heat of formation file is as follows (without the parenthesized comments):

```
17.54. fix eos/table/rx command 1193
```
# HEAT OF FORMATION TABLE  (one or more comment or blank lines)

(blank)

<table>
<thead>
<tr>
<th>Species</th>
<th>Heat of Formation</th>
</tr>
</thead>
<tbody>
<tr>
<td>h2</td>
<td>0.00</td>
</tr>
<tr>
<td>no2</td>
<td>0.34</td>
</tr>
<tr>
<td>n2</td>
<td>0.00</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
<tr>
<td>no</td>
<td>0.93</td>
</tr>
</tbody>
</table>

Note that the species can be listed in any order. The tag that is used as the species name must correspond with the tags used to define the reactions with the fix rx command.

Alternatively, corrections to the EOS can be included by specifying three additional columns that correspond to the energy correction, the temperature correction coefficient and molecule correction coefficient. In this case, the format of the file is as follows:

# HEAT OF FORMATION TABLE  (one or more comment or blank lines)

(blank)

<table>
<thead>
<tr>
<th>Species</th>
<th>Heat of Formation</th>
<th>Energy Correction</th>
<th>Temperature Correction Coefficient</th>
<th>Molecule Correction Coefficient</th>
</tr>
</thead>
<tbody>
<tr>
<td>h2</td>
<td>0.00 1.23 0.025 0.0</td>
<td></td>
<td></td>

</tbody>
</table>

Styles with a *gpu, intel, kk, omp, or opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 17.54.4 Restrictions

This command is part of the DPD-REACT package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This command also requires use of the *atom_style dpd* command.

The equation of state must be a monotonically increasing function.

An error will occur if the internal temperature or internal energies are not within the table cutoffs.
17.54.5 Related commands

fix rx, pair dpd/fdt

17.54.6 Default

none

17.55 fix evaporate command

17.55.1 Syntax

```
fix ID group-ID evaporate N M region-ID seed
```

- ID, group-ID are documented in `fix` command
- evaporate = style name of this fix command
- N = delete atoms every this many timesteps
- M = number of atoms to delete each time
- region-ID = ID of region within which to perform deletions
- seed = random number seed to use for choosing atoms to delete
- zero or more keyword/value pairs may be appended

```
keyword = molecule
  molecule value = no or yes
```

17.55.2 Examples

```
fix 1 solvent evaporate 1000 10 surface 49892
fix 1 solvent evaporate 1000 10 surface 38277 molecule yes
```

17.55.3 Description

Remove M atoms from the simulation every N steps. This can be used, for example, to model evaporation of solvent particles or molecules (i.e. drying) of a system. Every N steps, the number of atoms in the fix group and within the specified region are counted. M of these are chosen at random and deleted. If there are less than M eligible particles, then all of them are deleted.

If the setting for the `molecule` keyword is `no`, then only single atoms are deleted. In this case, you should insure you do not delete only a portion of a molecule (only some of its atoms), or LAMMPS will soon generate an error when it tries to find those atoms. LAMMPS will warn you if any of the atoms eligible for deletion have a non-zero molecule ID, but does not check for this at the time of deletion.

If the setting for the `molecule` keyword is `yes`, then when an atom is chosen for deletion, the entire molecule it is part of is deleted. The count of deleted atoms is incremented by the number of atoms in the molecule, which may make it exceed M. If the molecule ID of the chosen atom is 0, then it is assumed to not be part of a molecule, and just the single atom is deleted.
As an example, if you wish to delete 10 water molecules every $N$ steps, you should set $M$ to 30. If only the water’s oxygen atoms were in the fix group, then two hydrogen atoms would be deleted when an oxygen atom is selected for deletion, whether the hydrogen atoms are inside the evaporation region or not.

Note that neighbor lists are re-built on timesteps that atoms are removed. Thus you should not remove atoms too frequently or you will incur overhead due to the cost of building neighbor lists.

**Note:** If you are monitoring the temperature of a system where the atom count is changing due to evaporation, you typically should use the `compute_modify dynamic yes` command for the temperature compute you are using.

### 17.55.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the `fix_modify` options are relevant to this fix. This fix computes a global scalar, which can be accessed by various output commands. The scalar is the cumulative number of deleted atoms. The scalar value calculated by this fix is “intensive”.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during energy minimization.

### 17.55.5 Restrictions

None

### 17.55.6 Related commands

`fix deposit`

### 17.55.7 Default

The option defaults are molecule = no.

### 17.56 fix external command

#### 17.56.1 Syntax

```
fix ID group-ID external mode args
```

- ID, group-ID are documented in `fix` command
- external = style name of this fix command
- mode = `pf/callback` or `pf/array`
  - `pf/callback` args = Ncall Napply
    - Ncall = make callback every Ncall steps
    - Napply = apply callback forces every Napply steps
  - `pf/array` args = Napply
    - Napply = apply array forces every Napply steps
17.56.2 Examples

```
fix 1 all external pf/callback 1 1
fix 1 all external pf/callback 100 1
fix 1 all external pf/array 10
```

17.56.3 Description

This fix allows external programs that are running LAMMPS through its *library interface* to modify certain LAMMPS properties on specific timesteps, similar to the way other fixes do. The external driver can be a *C/C++ or Fortran program* or a *Python script*.

If mode is `pf/callback` then the fix will make a callback every `Ncall` timesteps or minimization iterations to the external program. The external program computes forces on atoms by setting values in an array owned by the fix. The fix then adds these forces to each atom in the group, once every `Napply` steps, similar to the way the *fix addforce* command works. Note that if `Ncall > Napply`, the force values produced by one callback will persist, and be used multiple times to update atom forces.

The callback function “foo” is invoked by the fix as:

```c
foo(void *ptr, bigint timestep, int nlocal, tagint *ids, double **x, double **fexternal);
```

The arguments are as follows:

- `ptr` = pointer provided by and simply passed back to external driver
- `timestep` = current LAMMPS timestep
- `nlocal` = # of atoms on this processor
- `ids` = list of atom IDs on this processor
- `x` = coordinates of atoms on this processor
- `fexternal` = forces to add to atoms on this processor

Note that `timestep` is a “bigint” which is defined in src/lmptype.h, typically as a 64-bit integer. And `ids` is a pointer to type “tagint” which is typically a 32-bit integer unless LAMMPS is compiled with `-DLAMMPS_BIGBIG`. For more info please see the *build settings* section of the manual. Finally, `fexternal` are the forces returned by the driver program.

The fix has a `set_callback()` method which the external driver can call to pass a pointer to its `foo()` function. See the `couple/lammps_quest/lmpqst.cpp` file in the LAMMPS distribution for an example of how this is done. This sample application performs classical MD using quantum forces computed by a density functional code *Quest*.

If mode is `pf/array` then the fix simply stores force values in an array. The fix adds these forces to each atom in the group, once every `Napply` steps, similar to the way the *fix addforce* command works.

The name of the public force array provided by the FixExternal class is

```
double **fexternal;
```

It is allocated by the FixExternal class as an (N,3) array where N is the number of atoms owned by a processor. The 3 corresponds to the fx, fy, fz components of force.
It is up to the external program to set the values in this array to the desired quantities, as often as desired. For example, the driver program might perform an MD run in stages of 1000 timesteps each. In between calls to the LAMMPS run command, it could retrieve atom coordinates from LAMMPS, compute forces, set values in fexternal, etc.

To use this fix during energy minimization, the energy corresponding to the added forces must also be set so as to be consistent with the added forces. Otherwise the minimization will not converge correctly. Correspondingly, the global virial needs to be updated to be use this fix with variable cell calculations (e.g. fix box/relax or fix npt).

This can be done from the external driver by calling these public methods of the FixExternal class:

```c
void set_energy_global(double eng);
void set_virial_global(double *virial);
```

where `eng` is the potential energy, and `virial` an array of the 6 stress tensor components. Eng is an extensive quantity, meaning it should be the sum over per-atom energies of all affected atoms. It should also be provided in energy units consistent with the simulation. See the details below for how to insure this energy setting is used appropriately in a minimization.

Additional public methods that the caller can use to update system properties are:

```c
void set_energy_peratom(double *eng);
void set_virial_peratom(double **virial);
void set_vector_length(int n);
void set_vector(int idx, double val);
```

These allow to set per-atom energy contributions, per-atom stress contributions, the length and individual values of a global vector of properties that the caller code may want to communicate to LAMMPS (e.g. for use in fix ave/time or in equal-style variables or for custom thermo output.

---

17.56.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify energy option is supported by this fix to add the potential energy set by the external driver to both the global potential energy and peratom potential energies of the system as part of thermodynamic output or output by the compute pe/atom command. The default setting for this fix is fix_modify energy yes. Note that this energy may be a fictitious quantity but it is needed so that the minimize command can include the forces added by this fix in a consistent manner. I.e. there is a decrease in potential energy when atoms move in the direction of the added force.

The fix_modify virial option is supported by this fix to add the contribution computed by the external program to both the global pressure and per-atom stress of the system via the compute pressure and compute stress/atom commands. The former can be accessed by thermodynamic output. The default setting for this fix is fix_modify virial yes.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the potential energy discussed above. The scalar stored by this fix is “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command.

**Note:** If you want the fictitious potential energy associated with the added forces to be included in the total potential energy of the system (the quantity being minimized), you MUST not disable the fix_modify energy option for this fix.

17.57 fix ffl command

17.57.1 Syntax

```
fix ID id-group ffl tau Tstart Tstop seed [flip-type]
```

- ID, group-ID are documented in `fix` command
- `ffl` = style name of this fix command
- `tau` = thermostat parameter (positive real)
- `Tstart, Tstop` = temperature ramp during the run
- `seed` = random number seed to use for generating noise (positive integer)
- one more value may be appended

```
flip-type = determines the flipping type, can be chosen between rescale - no_flip - → hard - soft, if no flip type is given, rescale will be chosen by default
```

17.57.2 Examples

```
fix 3 boundary ffl 10 300 300 31415
fix 1 all ffl 100 500 500 9265 soft
```

17.57.3 Description

Apply a Fast-Forward Langevin Equation (FFL) thermostat as described in *(Hijazi)*. Contrary to `fix langevin`, this fix performs both thermostating and evolution of the Hamiltonian equations of motion, so it should not be used together with `fix nve` – at least not on the same atom groups.

The time-evolution of a single particle undergoing Langevin dynamics is described by the equations

\[
\frac{dq}{dt} = \frac{p}{m},
\]

\[
\frac{dp}{dt} = -\gamma p + W + F,
\]
where $F$ is the physical force, $\gamma$ is the friction coefficient, and $W$ is a Gaussian random force.

The friction coefficient is the inverse of the thermostat parameter $\gamma = 1/\tau$, with $\tau$ the thermostat parameter $\text{tau}$. The thermostat parameter is given in the time units, $\gamma$ is in inverse time units.

Equilibrium sampling a temperature $T$ is obtained by specifying the target value as the $T_{\text{start}}$ and $T_{\text{stop}}$ arguments, so that the internal constants depending on the temperature are computed automatically.

The random number seed must be a positive integer. A Marsaglia random number generator is used. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.

The flipping type flip-type can be chosen between 4 types described in (Hijazi). The flipping operation occurs during the thermostatting step and it flips the momenta of the atoms. If no_flip is chosen, no flip will be executed and the integration will be the same as a standard Langevin thermostat (Bussi). The other flipping types are: rescale - hard - soft.

### 17.57.4 Restart, fix_modify, output, run start/stop, minimize info

The instantaneous values of the extended variables are written to binary restart files. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior. Note however that you should use a different seed each time you restart, otherwise the same sequence of random numbers will be used each time, which might lead to stochastic synchronization and subtle artifacts in the sampling.

The cumulative energy change in the system imposed by this fix is included in the thermodynamic output keywords $\text{ecouple}$ and $\text{econserve}$. See the thermo_style doc page for details.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

This fix can ramp its target temperature over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

### 17.57.5 Restrictions

In order to perform constant-pressure simulations please use fix press/berendsen, rather than fix npt, to avoid duplicate integration of the equations of motion.

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

fix cor all filter/corotate m 1.0
```

```
fix cor all filter/corotate b 4 19 a 3 5 2
```

17.58.3 Description

This fix implements a corotational filter for a mollified impulse method. In biomolecular simulations, it allows the usage of larger timesteps for long-range electrostatic interactions. For details, see (Fath).

When using `run_style respa` for a biomolecular simulation with high-frequency covalent bonds, the outer time-step is restricted to below \( \sim 4\text{fs} \) due to resonance problems. This fix filters the outer stage of the respa and thus a larger (outer) time-step can be used. Since in large biomolecular simulations the computation of the long-range electrostatic contributions poses a major bottleneck, this can significantly accelerate the simulation.

The filter computes a cluster decomposition of the molecular structure following the criteria indicated by the options \( a \), \( b \), \( t \) and \( m \). This process is similar to the approach in `fix shake`, however, the clusters are not kept constrained. Instead, the position is slightly modified only for the computation of long-range forces. A good cluster decomposition constitutes in building clusters which contain the fastest covalent bonds inside clusters.

If the clusters are chosen suitably, the `run_style respa` is stable for outer timesteps of at least 8fs.
17.58.4 Restart, fix_modify, output, run start/stop, minimize info

No information about these fixes is written to binary restart files. None of the fix_modify options are relevant to these fixes. No global or per-atom quantities are stored by these fixes for access by various output commands. No parameter of these fixes can be used with the start/stop keywords of the run command. These fixes are not invoked during energy minimization.

17.58.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

Currently, it does not support molecule templates.

1 = conserve current in this dimension

- zero or more keyword/value pairs may be appended
- keyword = energy

energy value = no or yes
   no = do not compute work done by this fix
   yes = compute work done by this fix
17.59.2 Examples

```
fix GD fluid flow/gauss 1 0 0
fix GD fluid flow/gauss 1 1 1 energy yes
```

17.59.3 Description

This fix implements the Gaussian dynamics (GD) method to simulate a system at constant mass flux \((\text{Strong})\). GD is a nonequilibrium molecular dynamics simulation method that can be used to study fluid flows through pores, pipes, and channels. In its original implementation GD was used to compute the pressure required to achieve a fixed mass flux through an opening. The flux can be conserved in any combination of the directions, \(x\), \(y\), or \(z\), using \(x\text{flag}, y\text{flag}, z\text{flag}\).

This fix does not initialize a net flux through a system, it only conserves the center-of-mass momentum that is present when the fix is declared in the input script. Use the \textit{velocity} command to generate an initial center-of-mass momentum.

GD applies an external fluctuating gravitational field that acts as a driving force to keep the system away from equilibrium. To maintain steady state, a profile-unbiased thermostat must be implemented to dissipate the heat that is added by the driving force. \textit{Compute temp/profile} can be used to implement a profile-unbiased thermostat.

A common use of this fix is to compute a pressure drop across a pipe, pore, or membrane. The pressure profile can be computed in LAMMPS with \textit{compute stress/atom} and \textit{fix ave/chunk}, or with the hardy method in \textit{fix atc}. Note that the simple \textit{compute stress/atom} method is only accurate away from inhomogeneities in the fluid, such as fixed wall atoms. Further, the computed pressure profile must be corrected for the acceleration applied by GD before computing a pressure drop or comparing it to other methods, such as the pump method \((\text{Zhu})\). The pressure correction is discussed and described in \((\text{Strong})\).

For a complete example including the considerations discussed above, see the examples/PACKAGES/flow_gauss directory.

**Note:** Only the flux of the atoms in group-ID will be conserved. If the velocities of the group-ID atoms are coupled to the velocities of other atoms in the simulation, the flux will not be conserved. For example, in a simulation with fluid atoms and harmonically constrained wall atoms, if a single thermostat is applied to group \textit{all}, the fluid atom velocities will be coupled to the wall atom velocities, and the flux will not be conserved. This issue can be avoided by thermostatting the fluid and wall groups separately.

Adding an acceleration to atoms does work on the system. This added energy can be optionally subtracted from the potential energy for the thermodynamic output (see below) to check that the timestep is small enough to conserve energy. Since the applied acceleration is fluctuating in time, the work cannot be computed from a potential. As a result, computing the work is slightly more computationally expensive than usual, so it is not performed by default. To invoke the work calculation, use the \textit{energy} keyword. The \textit{fix_modify energy} option also invokes the work calculation, and overrides an \textit{energy no} setting here. If neither \textit{energy yes} or \textit{fix_modify energy yes} are set, the global scalar computed by the fix will return zero.

**Note:** In order to check energy conservation, any other fixes that do work on the system must have \textit{fix_modify energy yes} set as well. This includes thermostat fixes and any constraints that hold the positions of wall atoms fixed, such as \textit{fix spring/self}.

If this fix is used in a simulation with the \textit{rRESPA} integrator, the applied acceleration must be computed and applied at the same \textit{rRESPA} level as the interactions between the flowing fluid and the obstacle. The \textit{rRESPA} level at which the acceleration is applied can be changed using the \textit{fix_modify respa} option discussed below. If the flowing fluid and the obstacle interact through multiple interactions that are computed at different \textit{rRESPA} levels, then there must be a separate flow/gauss fix for each level. For example, if the flowing fluid and obstacle interact through pairwise and
long-range Coulomb interactions, which are computed at rRESPA levels 3 and 4, respectively, then there must be two separate flow/gauss fixes, one that specifies \texttt{fix\_modify\ respa 3} and one with \texttt{fix\_modify\ respa 4}.

17.59.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to \textit{binary restart files}.

The \texttt{fix\_modify energy} option is supported by this fix to add the potential energy added by the fix to the global potential energy of the system as part of \textit{thermodynamic output}. The default setting for this fix is \texttt{fix\_modify energy no}.

The \texttt{fix\_modify respa} option is supported by this fix. This allows the user to set at which level of the rRESPA integrator the fix computes and adds the external acceleration. Default is the outermost level.

This fix computes a global scalar and a global 3-vector of forces, which can be accessed by various \textit{output commands}. The scalar is the negative of the work done on the system, see the discussion above. It is only calculated if the \texttt{energy} keyword is enabled or \texttt{fix\_modify\ energy yes} is set.

The vector is the total force that this fix applied to the group of atoms on the current timestep. The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the \texttt{start/stop} keywords of the \textit{run} command.

This fix is not invoked during \textit{energy minimization}.

17.59.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the \textit{Build package} page for more info.

17.59.6 Related commands

\texttt{fix addforce, compute temp/profile, velocity}

The option default for the \texttt{energy} keyword is \texttt{energy = no}.

17.60 fix freeze command

Accelerator Variants: freeze/kk

17.60.1 Syntax

<table>
<thead>
<tr>
<th>fix ID group-ID freeze</th>
</tr>
</thead>
</table>

- ID, group-ID are documented in fix command
- freeze = style name of this fix command

17.60.2 Examples

| fix 2 bottom freeze |

17.60.3 Description

Zero out the force and torque on a granular particle. This is useful for preventing certain particles from moving in a simulation. The granular pair styles also detect if this fix has been defined and compute interactions between frozen and non-frozen particles appropriately, as if the frozen particle has infinite mass. A similar functionality for normal (point) particles can be obtained using fix setforce.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

17.60.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix.

This fix computes a global 3-vector of forces, which can be accessed by various output commands. This is the total force on the group of atoms before the forces on individual atoms are changed by the fix. The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.
17.60.5 Restrictions

This fix is part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

There can only be a single freeze fix defined. This is because other the granular pair styles treat frozen particles differently and need to be able to reference a single group to which this fix is applied.

17.61 fix gcmc command

17.61.1 Syntax

```
fix ID group-ID gcmc N X M type seed T mu displace keyword values ...
```

- **ID, group-ID** are documented in `fix` command
- **gcmc** = style name of this fix command
- **N** = invoke this fix every N steps
- **X** = average number of GCMC exchanges to attempt every N steps
- **M** = average number of MC moves to attempt every N steps
- **type** = atom type for inserted atoms (must be 0 if mol keyword used)
- **seed** = random # seed (positive integer)
- **T** = temperature of the ideal gas reservoir (temperature units)
- **mu** = chemical potential of the ideal gas reservoir (energy units)
- **displace** = maximum Monte Carlo translation distance (length units)
- **zero or more keyword/value pairs may be appended to args**

```
keyword = mol, region, maxangle, pressure, fugacity_coeff, full_energy, charge, ...
group, grouptype, intra_energy, tfac_insert, or overlap_cutoff
```

- **mol value** = template-ID
  - template-ID = ID of molecule template specified in a separate molecule command
- **mcmoves values** = Patomtrans Pmoltrans Pmolrotate
  - Patomtrans = proportion of atom translation MC moves
  - Pmoltrans = proportion of molecule translation MC moves
  - Pmolrotate = proportion of molecule rotation MC moves
- **rigid value** = fix-ID
  - fix-ID = ID of `fix rigid/small` command
- **shake value** = fix-ID
  - fix-ID = ID of `fix shake` command
region value = region-ID
region-ID = ID of region where GCMC exchanges and MC moves are allowed
maxangle value = maximum molecular rotation angle (degrees)
pressure value = pressure of the gas reservoir (pressure units)
fugacity_coeff value = fugacity coefficient of the gas reservoir (unitless)
full_energy = compute the entire system energy when performing GCMC exchanges and MC moves
charge value = charge of inserted atoms (charge units)
group value = group-ID
group-ID = group-ID for inserted atoms (string)
grouptype values = type group-ID
type = atom type (int)
group-ID = group-ID for inserted atoms (string)
intra_energy value = intramolecular energy (energy units)
tfac_insert value = scale up/down temperature of inserted atoms (unitless)
overlap_cutoff value = maximum pair distance for overlap rejection (distance units)
max value = Maximum number of molecules allowed in the system
min value = Minimum number of molecules allowed in the system

17.61.2 Examples

```
fix 2 gas gcmc 10 1000 1000 2 29494 298.0 -0.5 0.01
fix 3 water gcmc 10 100 100 0 3456543 3.0 -2.5 0.1 mol my_one_water maxangle 180 full_energy
fix 4 my_gas gcmc 1 10 10 1 123456543 300.0 -12.5 1.0 region disk
```

17.61.3 Description

This fix performs grand canonical Monte Carlo (GCMC) exchanges of atoms or molecules with an imaginary ideal gas reservoir at the specified T and chemical potential (\(\mu\)) as discussed in [Frenkel]. It also attempts Monte Carlo (MC) moves (translations and molecule rotations) within the simulation cell or region. If used with the fix nvt command, simulations in the grand canonical ensemble (\(\mu VT\), constant chemical potential, constant volume, and constant temperature) can be performed. Specific uses include computing isotherms in microporous materials, or computing vapor-liquid coexistence curves.

Every N timesteps the fix attempts both GCMC exchanges (insertions or deletions) and MC moves of gas atoms or molecules. On those timesteps, the average number of attempted GCMC exchanges is X, while the average number of attempted MC moves is M. For GCMC exchanges of either molecular or atomic gasses, these exchanges can be either deletions or insertions, with equal probability.

The possible choices for MC moves are translation of an atom, translation of a molecule, and rotation of a molecule. The relative amounts of each are determined by the optional \texttt{mcmoves} keyword (see below). The default behavior is as follows. If the \texttt{mol} keyword is used, only molecule translations and molecule rotations are performed with equal probability. Conversely, if the \texttt{mol} keyword is not used, only atom translations are performed. M should typically be chosen to be approximately equal to the expected number of gas atoms or molecules of the given type within the simulation cell or region, which will result in roughly one MC move per atom or molecule per MC cycle.

All inserted particles are always added to two groups: the default group “all” and the fix group specified in the fix command. In addition, particles are also added to any groups specified by the \texttt{group} and \texttt{grouptype} keywords. If inserted particles are individual atoms, they are assigned the atom type given by the type argument. If they are molecules, the type argument has no effect and must be set to zero. Instead, the type of each atom in the inserted molecule is specified in the file read by the \texttt{molecule} command.
Note: Care should be taken to apply fix gcmc only to a group that contains only those atoms and molecules that you wish to manipulate using Monte Carlo. Hence it is generally not a good idea to specify the default group “all” in the fix command, although it is allowed.

This fix cannot be used to perform GCMC insertions of gas atoms or molecules other than the exchanged type, but GCMC deletions, and MC translations, and rotations can be performed on any atom/molecule in the fix group. All atoms in the simulation cell can be moved using regular time integration translations, e.g. via fix nvt, resulting in a hybrid GCMC+MD simulation. A smaller-than-usual timestep size may be needed when running such a hybrid simulation, especially if the inserted molecules are not well equilibrated.

This command may optionally use the region keyword to define an exchange and move volume. The specified region must have been previously defined with a region command. It must be defined with side = in. Insertion attempts occur only within the specified region. For non-rectangular regions, random trial points are generated within the rectangular bounding box until a point is found that lies inside the region. If no valid point is generated after 1000 trials, no insertion is performed, but it is counted as an attempted insertion. Move and deletion attempt candidates are selected from gas atoms or molecules within the region. If there are no candidates, no move or deletion is performed, but it is counted as an attempt move or deletion. If an attempted move places the atom or molecule center-of-mass outside the specified region, a new attempted move is generated. This process is repeated until the atom or molecule center-of-mass is inside the specified region.

If used with fix nvt, the temperature of the imaginary reservoir, T, should be set to be equivalent to the target temperature used in fix nvt. Otherwise, the imaginary reservoir will not be in thermal equilibrium with the simulation cell. Also, it is important that the temperature used by fix nvt be dynamic/dof, which can be achieved as follows:

```
compute mdtemp mdatoms temp
compute_modify mdtemp dynamic/dof yes
fix mdnvt mdatoms nvt temp 300.0 300.0 10.0
fix_modify mdnvt temp mdtemp
```

Note that neighbor lists are re-built every timestep that this fix is invoked, so you should not set N to be too small. However, periodic rebuilds are necessary in order to avoid dangerous rebuilds and missed interactions. Specifically, avoid performing so many MC translations per timestep that atoms can move beyond the neighbor list skin distance. See the neighbor command for details.

When an atom or molecule is to be inserted, its coordinates are chosen at a random position within the current simulation cell or region, and new atom velocities are randomly chosen from the specified temperature distribution given by T. The effective temperature for new atom velocities can be increased or decreased using the optional keyword tfac_insert (see below). Relative coordinates for atoms in a molecule are taken from the template molecule provided by the user. The center of mass of the molecule is placed at the insertion point. The orientation of the molecule is chosen at random by rotating about this point.

Individual atoms are inserted, unless the mol keyword is used. It specifies a template-ID previously defined using the molecule command, which reads a file that defines the molecule. The coordinates, atom types, charges, etc., as well as any bonding and special neighbor information for the molecule can be specified in the molecule file. See the molecule command for details. The only settings required to be in this file are the coordinates and types of atoms in the molecule.

When not using the mol keyword, you should ensure you do not delete atoms that are bonded to other atoms, or LAMMPS will soon generate an error when it tries to find bonded neighbors. LAMMPS will warn you if any of the atoms eligible for deletion have a non-zero molecule ID, but does not check for this at the time of deletion.

If you wish to insert molecules using the mol keyword that will be treated as rigid bodies, use the rigid keyword, specifying as its value the ID of a separate fix rigid/small command which also appears in your input script.

Note: If you wish the new rigid molecules (and other rigid molecules) to be thermostatted correctly via fix rigid/small/nvt or fix rigid/small/npt, then you need to use the “fix_modify dynamic/dof yes” command for the rigid
If you wish to insert molecules via the `mol` keyword, that will have their bonds or angles constrained via SHAKE, use the `shake` keyword, specifying as its value the ID of a separate `fix shake` command which also appears in your input script.

Optionally, users may specify the relative amounts of different MC moves using the `mcmoves` keyword. The values `Patomtrans`, `Pmoltrans`, `Pmolrotate` specify the average proportion of atom translations, molecule translations, and molecule rotations, respectively. The values must be non-negative integers or real numbers, with at least one non-zero value. For example, `(10,30,0)` would result in 25% of the MC moves being atomic translations, 75% molecular translations, and no molecular rotations.

Optionally, users may specify the maximum rotation angle for molecular rotations using the `maxangle` keyword and specifying the angle in degrees. Rotations are performed by generating a random point on the unit sphere and a random rotation angle on the range [0,maxangle). The molecule is then rotated by that angle about an axis passing through the molecule center of mass. The axis is parallel to the unit vector defined by the point on the unit sphere. The same procedure is used for randomly rotating molecules when they are inserted, except that the maximum angle is 360 degrees.

Note that `fix gcmc` does not use configurational bias MC or any other kind of sampling of intramolecular degrees of freedom. Inserted molecules can have different orientations, but they will all have the same intramolecular configuration, which was specified in the molecule command input.

For atomic gasses, inserted atoms have the specified atom type, but deleted atoms are any atoms that have been inserted or that already belong to the fix group. For molecular gasses, exchanged molecules use the same atom types as in the template molecule supplied by the user. In both cases, exchanged atoms/molecules are assigned to two groups: the default group “all” and the fix group (which can also be “all”).

The chemical potential is a user-specified input parameter defined as:

\[
\mu = \mu^{id} + \mu^{ex}
\]

The second term \(\mu^{ex}\) is the excess chemical potential due to energetic interactions and is formally zero for the fictitious gas reservoir but is non-zero for interacting systems. So, while the chemical potential of the reservoir and the simulation cell are equal, \(\mu^{ex}\) is not, and as a result, the densities of the two are generally quite different. The first term \(\mu^{id}\) is the ideal gas contribution to the chemical potential. \(\mu^{id}\) can be related to the density or pressure of the fictitious gas reservoir by:

\[
\mu^{id} = kT \ln \rho \Lambda^3 = kT \ln \frac{\phi P \Lambda^3}{kT}
\]

where \(k\) is Boltzman’s constant, \(T\) is the user-specified temperature, \(\rho\) is the number density, \(P\) is the pressure, and \(\phi\) is the fugacity coefficient. The constant \(\Lambda\) is required for dimensional consistency. For all unit styles except \(lj\) it is defined as the thermal de Broglie wavelength

\[
\Lambda = \sqrt{\frac{\hbar^2}{2\pi mkT}}
\]

where \(\hbar\) is Planck’s constant, and \(m\) is the mass of the exchanged atom or molecule. For unit style \(lj\), \(\Lambda\) is simply set to unity. Note that prior to March 2017, \(\Lambda\) for unit style \(lj\) was calculated using the above formula with \(\hbar\) set to the rather specific value of 0.18292026. Chemical potential under the old definition can be converted to an equivalent value under the new definition by subtracting \(3kT \ln(\Lambda_{old})\).

As an alternative to specifying \(\mu\) directly, the ideal gas reservoir can be defined by its pressure \(P\) using the `pressure` keyword, in which case the user-specified chemical potential is ignored. The user may also specify the fugacity coefficient \(\phi\) using the `fugacity_coeff` keyword, which defaults to unity.
The `full_energy` option means that the fix calculates the total potential energy of the entire simulated system, instead of just the energy of the part that is changed. The total system energy before and after the proposed GCMC exchange or MC move is then used in the Metropolis criterion to determine whether or not to accept the proposed change. By default, this option is off, in which case only partial energies are computed to determine the energy difference due to the proposed change.

The `full_energy` option is needed for systems with complicated potential energy calculations, including the following:

- long-range electrostatics (kspace)
- many-body pair styles
- hybrid pair styles
- eam pair styles
- tail corrections
- need to include potential energy contributions from other fixes

In these cases, LAMMPS will automatically apply the `full_energy` keyword and issue a warning message.

When the `mol` keyword is used, the `full_energy` option also includes the intramolecular energy of inserted and deleted molecules, whereas this energy is not included when `full_energy` is not used. If this is not desired, the `intra_energy` keyword can be used to define an amount of energy that is subtracted from the final energy when a molecule is inserted, and subtracted from the initial energy when a molecule is deleted. For molecules that have a non-zero intramolecular energy, this will ensure roughly the same behavior whether or not the `full_energy` option is used.

Inserted atoms and molecules are assigned random velocities based on the specified temperature $T$. Because the relative velocity of all atoms in the molecule is zero, this may result in inserted molecules that are systematically too cold. In addition, the intramolecular potential energy of the inserted molecule may cause the kinetic energy of the molecule to quickly increase or decrease after insertion. The `tfac_insert` keyword allows the user to counteract these effects by changing the temperature used to assign velocities to inserted atoms and molecules by a constant factor. For a particular application, some experimentation may be required to find a value of `tfac_insert` that results in inserted molecules that equilibrate quickly to the correct temperature.

Some fixes have an associated potential energy. Examples of such fixes include: `efield`, `gravity`, `addforce`, `langevin`, `restrain`, `temp/berendsen`, `temp/rescale`, and `wall` fixes. For that energy to be included in the total potential energy of the system (the quantity used when performing GCMC exchange and MC moves), you MUST enable the `fix_modify energy` option for that fix. The doc pages for individual `fix` commands specify if this should be done.

Use the `charge` option to insert atoms with a user-specified point charge. Note that doing so will cause the system to become non-neutral. LAMMPS issues a warning when using long-range electrostatics (kspace) with non-neutral systems. See the `compute group/group` documentation for more details about simulating non-neutral systems with kspace on.

Use of this fix typically will cause the number of atoms to fluctuate, therefore, you will want to use the `compute_modify dynamic/dof` command to insure that the current number of atoms is used as a normalizing factor each time temperature is computed. A simple example of this is:

```
compute_modify thermo_temp dynamic yes
```

A more complicated example is listed earlier on this page in the context of NVT dynamics.

**Note:** If the density of the cell is initially very small or zero, and increases to a much larger density after a period of equilibration, then certain quantities that are only calculated once at the start (kspace parameters) may no longer be accurate. The solution is to start a new simulation after the equilibrium density has been reached.
With some pair_styles, such as Buckingham, Born-Mayer-Huggins and ReaxFF, two atoms placed close to each other may have an arbitrary large, negative potential energy due to the functional form of the potential. While these unphysical configurations are inaccessible to typical dynamical trajectories, they can be generated by Monte Carlo moves. The overlap cutoff keyword suppresses these moves by effectively assigning an infinite positive energy to all new configurations that place any pair of atoms closer than the specified overlap cutoff distance.

The max and min keywords allow for the restriction of the number of atoms in the simulation. They automatically reject all insertion or deletion moves that would take the system beyond the set boundaries. Should the system already be beyond the boundary, only moves that bring the system closer to the bounds may be accepted.

The group keyword adds all inserted atoms to the group of the group-ID value. The grouptype keyword adds all inserted atoms of the specified type to the group of the group-ID value.

17.61.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the fix to binary restart files. This includes information about the random number generator seed, the next timestep for MC exchanges, the number of MC step attempts and successes etc. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

Note: For this to work correctly, the timestep must not be changed after reading the restart with reset_timestep. The fix will try to detect it and stop with an error.

None of the fix_modify options are relevant to this fix.

This fix computes a global vector of length 8, which can be accessed by various output commands. The vector values are the following global cumulative quantities:

- 1 = translation attempts
- 2 = translation successes
- 3 = insertion attempts
- 4 = insertion successes
- 5 = deletion attempts
- 6 = deletion successes
- 7 = rotation attempts
- 8 = rotation successes

The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.
17.61.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Do not set “neigh_modify once yes” or else this fix will never be called. Reneighboring is required.

Only usable for 3D simulations.

Can be run in parallel, but aspects of the GCMC part will not scale well in parallel. Currently, molecule translations and rotations are not supported with more than one MPI process. It is still possible to do parallel molecule exchange without translation and rotation moves by setting MC moves to zero and/or by using the mcmove keyword with Pmoltrans = Pmolrotate = 0.

When using fix gcmc in combination with fix shake or fix rigid, only GCMC exchange moves are supported, so the argument M must be zero.

When using fix gcmc in combination with fix rigid, deletion of the last remaining molecule is not allowed for technical reasons, and so the molecule count will never drop below 1, regardless of the specified chemical potential.

Note that very lengthy simulations involving insertions/deletions of billions of gas molecules may run out of atom or molecule IDs and trigger an error, so it is better to run multiple shorter-duration simulations. Likewise, very large molecules have not been tested and may turn out to be problematic.

Use of multiple fix gcmc commands in the same input script can be problematic if using a template molecule. The issue is that the user-referenced template molecule in the second fix gcmc command may no longer exist since it might have been deleted by the first fix gcmc command. An existing template molecule will need to be referenced by the user for each subsequent fix gcmc command.

17.61.6 Related commands

fix atom/swap, fix nvt, neighbor, fix deposit, fix evaporate, delete_atoms

17.61.7 Default

The option defaults are mol = no, maxangle = 10, overlap_cutoff = 0.0, fugacity_coeff = 1.0, intra_energy = 0.0, tfac_insert = 1.0. (Patomtrans, Pmoltrans, Pmolrotate) = (1, 0, 0) for mol = no and (0, 1, 1) for mol = yes. full_energy = no, except for the situations where full_energy is required, as listed above.

17.62 fix gld command

17.62.1 Syntax

\[
\text{fix ID group-ID gld Tstart Tstop N_k seed series c_1 tau_1 ... c_N_k tau_N_k keyword_...values ...}
\]

- ID, group-ID are documented in fix command
- gld = style name of this fix command
- Tstart, Tstop = desired temperature at start/end of run (temperature units)
- \( N_k \) = number of terms in the Prony series representation of the memory kernel
- seed = random number seed to use for white noise (positive integer)
- series = pprony is presently the only available option
- \( c_k \) = the weight of the \( k \)th term in the Prony series (mass per time units)
- \( \tau_k \) = the time constant of the \( k \)th term in the Prony series (time units)
- zero or more keyword/value pairs may be appended

Keyword = frozen or zero
  - frozen value = no or yes
  - no = initialize extended variables using values drawn from equilibrium distribution at \( T_{\text{start}} \)
  - yes = initialize extended variables to zero (i.e., from equilibrium distribution at zero temperature)
  - zero value = no or yes
  - no = do not set total random force to zero
  - yes = set total random force to zero

### 17.62.2 Examples

```plaintext
fix 1 all gld 1.0 1.0 2 82885 pprony 0.5 1.0 1.0 2.0 frozen yes zero yes
fix 3 rouse gld 7.355 7.355 4 48823 pprony 107.1 0.02415 186.0 0.04294 428.6 0.09661 1714 0.38643
```

### 17.62.3 Description

Applies Generalized Langevin Dynamics to a group of atoms, as described in (Baczewski). This is intended to model the effect of an implicit solvent with a temporally non-local dissipative force and a colored Gaussian random force, consistent with the Fluctuation-Dissipation Theorem. The functional form of the memory kernel associated with the temporally non-local force is constrained to be a Prony series.

**Note:** While this fix bears many similarities to fix langevin, it has one significant difference. Namely, fix gld performs time integration, whereas fix langevin does NOT. To this end, the specification of another fix to perform time integration, such as fix nve, is NOT necessary.

With this fix active, the force on the \( j \)th atom is given as

\[
F_j(t) = F_j^C(t) - \int_0^t \Gamma_j(t-s) v_j(s) \, ds + F_j^R(t)
\]

\[
\Gamma_j(t-s) = \sum_{k=1}^{N_k} \frac{c_k}{\tau_k} e^{-(t-s)/\tau_k}
\]

\[
\langle F_j^R(t), F_j^R(s) \rangle = k_B T \Gamma_j(t-s)
\]

Here, the first term is representative of all conservative (pairwise, bonded, etc) forces external to this fix, the second is the temporally non-local dissipative force given as a Prony series, and the third is the colored Gaussian random force.

The Prony series form of the memory kernel is chosen to enable an extended variable formalism, with a number of exemplary mathematical features discussed in (Baczewski). In particular, \( 3N_k \) extended variables are added to each
atom, which effect the action of the memory kernel without having to explicitly evaluate the integral over time in the second term of the force. This also has the benefit of requiring the generation of uncorrelated random forces, rather than correlated random forces as specified in the third term of the force.

Presently, the Prony series coefficients are limited to being greater than or equal to zero, and the time constants are limited to being greater than zero. To this end, the value of series MUST be set to pprony, for now. Future updates will allow for negative coefficients and other representations of the memory kernel. It is with these updates in mind that the series option was included.

The units of the Prony series coefficients are chosen to be mass per time to ensure that the numerical integration scheme stably approaches the Newtonian and Langevin limits. Details of these limits, and the associated numerical concerns are discussed in (Baczewski).

The desired temperature at each timestep is ramped from $T_{\text{start}}$ to $T_{\text{stop}}$ over the course of the next run.

The random seed must be a positive integer. A Marsaglia random number generator is used. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.

The keyword/value option pairs are used in the following ways.

The keyword frozen can be used to specify how the extended variables associated with the GLD memory kernel are initialized. Specifying no (the default), the initial values are drawn at random from an equilibrium distribution at $T_{\text{start}}$, consistent with the Fluctuation-Dissipation Theorem. Specifying yes, initializes the extended variables to zero.

The keyword zero can be used to eliminate drift due to the thermostat. Because the random forces on different atoms are independent, they do not sum exactly to zero. As a result, this fix applies a small random force to the entire system, and the center-of-mass of the system undergoes a slow random walk. If the keyword zero is set to yes, the total random force is set exactly to zero by subtracting off an equal part of it from each atom in the group. As a result, the center-of-mass of a system with zero initial momentum will not drift over time.

17.62.4 Restart, fix_modify, output, run start/stop, minimize info

The instantaneous values of the extended variables are written to binary restart files. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior.

None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands.

This fix can ramp its target temperature over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.
17.62.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

17.62.6 Related commands

fix langevin, fix viscous, pair_style dpd/tstat

17.62.7 Default

The option defaults are frozen = no, zero = no.

17.63 fix gle command

17.63.1 Syntax

```
fix ID id-group gle Ns Tstart Tstop seed Amatrix [noneq Cmatrix] [every stride]
```

- ID, group-ID are documented in fix command
- gle = style name of this fix command
- Ns = number of additional fictitious momenta
- Tstart, Tstop = temperature ramp during the run
- Amatrix = file to read the drift matrix A from
- seed = random number seed to use for generating noise (positive integer)
- zero or more keyword/value pairs may be appended

```
keyword = noneq or every
    noneq Cmatrix = file to read the non-equilibrium covariance matrix from
every stride = apply the GLE once every time steps. Reduces the accuracy
    of the integration of the GLE, but has *no effect* on the accuracy of
    equilibrium
```

It might change sampling properties when used together with noneq.

17.63.2 Examples

```
 fix 3 boundary gle 6 300 300 31415 smart.A
 fix 1 all gle 6 300 300 31415 qt-300k.A noneq qt-300k.C
```
17.63.3 Description

Apply a Generalized Langevin Equation (GLE) thermostat as described in (Ceriotti). The formalism allows one to obtain a number of different effects ranging from efficient sampling of all vibrational modes in the system to inexpensive (approximate) modelling of nuclear quantum effects. Contrary to fix langevin, this fix performs both thermostating and evolution of the Hamiltonian equations of motion, so it should not be used together with fix nve – at least not on the same atom groups.

Each degree of freedom in the thermostatted group is supplemented with Ns additional degrees of freedom s, and the equations of motion become

\[
\frac{dq}{dt} = \frac{p}{m} \\
\frac{d(p,s)}{dt} = (F,0) - A(p,s) + B \frac{dW}{dt}
\]

where \( F \) is the physical force, \( A \) is the drift matrix (that generalizes the friction in Langevin dynamics), \( B \) is the diffusion term and \( dW/dt \) un-correlated Gaussian random forces. The \( A \) matrix couples the physical \((q,p)\) dynamics with that of the additional degrees of freedom, and makes it possible to obtain effectively a history-dependent noise and friction kernel.

The drift matrix should be given as an external file \( Afile \), as a \((Ns+1 \times Ns+1)\) matrix in inverse time units. Matrices that are optimal for a given application and the system of choice can be obtained from (GLE4MD).

Equilibrium sampling a temperature \( T \) is obtained by specifying the target value as the \( Tstart \) and \( Tstop \) arguments, so that the diffusion matrix that gives canonical sampling for a given \( A \) is computed automatically. However, the GLE framework also allow for non-equilibrium sampling, that can be used for instance to model inexpensively zero-point energy effects (Ceriotti2). This is achieved specifying the noneq keyword followed by the name of the file that contains the static covariance matrix for the non-equilibrium dynamics. Please note, that the covariance matrix is expected to be given in temperature units.

Since integrating GLE dynamics can be costly when used together with simple potentials, one can use the every optional keyword to apply the Langevin terms only once every several MD steps, in a multiple time-step fashion. This should be used with care when doing non-equilibrium sampling, but should have no effect on equilibrium averages when using canonical sampling.

The random number seed must be a positive integer. A Marsaglia random number generator is used. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.

Note also that the Generalized Langevin Dynamics scheme that is implemented by the fix gld scheme is closely related to the present one. In fact, it should be always possible to cast the Prony series form of the memory kernel used by GLD into an appropriate input matrix for fix gle. While the GLE scheme is more general, the form used by fix gld can be more directly related to the representation of an implicit solvent environment.

17.63.4 Restart, fix_modify, output, run start/stop, minimize info

The instantaneous values of the extended variables are written to binary restart files. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior. Note however that you should use a different seed each time you restart, otherwise the same sequence of random numbers will be used each time, which might lead to stochastic synchronization and subtle artifacts in the sampling.

The cumulative energy change in the system imposed by this fix is included in the thermodynamic output keywords ecouple and econserve. See the thermo_style doc page for details.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.
This fix can ramp its target temperature over multiple runs, using the `start` and `stop` keywords of the `run` command. See the `run` command for details of how to do this.

This fix is not invoked during energy minimization.

### 17.63.5 Restrictions

The GLE thermostat in its current implementation should not be used with rigid bodies, SHAKE or RATTLE. It is expected that all the thermostatted degrees of freedom are fully flexible, and the sampled ensemble will not be correct otherwise.

In order to perform constant-pressure simulations please use `fix press/berendsen`, rather than `fix npt`, to avoid duplicate integration of the equations of motion.

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

### 17.64 fix gravity command

Accelerator Variants: `gravity/omp`, `gravity/kk`

#### 17.64.1 Syntax

```plaintext
fix ID group gravity magnitude style args
```

- ID, group are documented in `fix` command
- `gravity` = style name of this fix command
- `magnitude` = size of acceleration (force/mass units)
- `magnitude` can be a variable (see below)
- `style` = `chute` or `spherical` or `gradient` or `vector`
  - `chute` args = `angle`
    - `angle` = angle in +x away from -z or -y axis in 3d/2d (in degrees)
    - `angle` can be a variable (see below)
  - `spherical` args = `phi` `theta`
    - `phi` = azimuthal angle from +x axis (in degrees)
    - `theta` = angle from +z or +y axis in 3d/2d (in degrees)
    - `phi` or `theta` can be a variable (see below)
  - `vector` args = `x` `y` `z`
x y z = vector direction to apply the acceleration
x or y or z can be a variable (see below)

17.64.3 Description

Impose an additional acceleration on each particle in the group. This fix is typically used with granular systems to include a “gravity” term acting on the macroscopic particles. More generally, it can represent any kind of driving field, e.g. a pressure gradient inducing a Poiseuille flow in a fluid. Note that this fix operates differently than the fix addforce command. The addforce fix adds the same force to each atom, independent of its mass. This command imparts the same acceleration to each atom (force/mass).

The magnitude of the acceleration is specified in force/mass units. For granular systems (LJ units) this is typically 1.0. See the units command for details.

Style chute is typically used for simulations of chute flow where the specified angle is the chute angle, with flow occurring in the +x direction. For 3d systems, the tilt is away from the z axis; for 2d systems, the tilt is away from the y axis.

Style spherical allows an arbitrary 3d direction to be specified for the acceleration vector. Phi and theta are defined in the usual spherical coordinates. Thus for acceleration acting in the -z direction, theta would be 180.0 (or -180.0). Theta = 90.0 and phi = -90.0 would mean acceleration acts in the -y direction. For 2d systems, phi is ignored and theta is an angle in the xy plane where theta = 0.0 is the y-axis.

Style vector imposes an acceleration in the vector direction given by (x,y,z). Only the direction of the vector is important; it’s length is ignored. For 2d systems, the z component is ignored.

Any of the quantities magnitude, angle, phi, theta, x, y, z which define the gravitational magnitude and direction, can be specified as an equal-style variable. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the quantity. You should insure that the variable calculates a result in the appropriate units, e.g. force/mass or degrees.

Equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent gravitational field.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
17.64.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The **fix_modify energy** option is supported by this fix to add the gravitational potential energy of the system to the global potential energy of the system as part of thermodynamic output. The default setting for this fix is *fix_modify energy no*.

The **fix_modify respa** option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar which can be accessed by various output commands. This scalar is the gravitational potential energy of the particles in the defined field, namely mass * (g dot x) for each particles, where x and mass are the particles position and mass, and g is the gravitational field. The scalar value calculated by this fix is “extensive”. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during energy minimization.

17.65.3 Description

This fix implements the molecular dynamics version of the generalized replica exchange method (gREM) originally developed by (Kim), which uses non-Boltzmann ensembles to sample over first order phase transitions. The is done by defining replicas with an enthalpy dependent effective temperature

$$T_{eff} = \lambda + \eta(H - H_0)$$

with $\eta$ negative and steep enough to only intersect the characteristic microcanonical temperature (Ts) of the system once, ensuring a unimodal enthalpy distribution in that replica. $\lambda$ is the intercept and effects the generalized ensemble similar to how temperature effects a Boltzmann ensemble. $H_0$ is a reference enthalpy, and is typically set as the lowest desired sampled enthalpy. Further explanation can be found in our recent papers (Malolepsza).

This fix requires a Nose-Hoover thermostat fix reference passed to the grem as thermostat-ID. Two distinct temperatures exist in this generalized ensemble, the effective temperature defined above, and a kinetic temperature that controls the velocity distribution of particles as usual. Either constant volume or constant pressure algorithms can be used.

The fix enforces a generalized ensemble in a single replica only. Typically, this ideology is combined with replica exchange with replicas differing by $\lambda$ only for simplicity, but this is not required. A multi-replica simulation can be run within the LAMMPS environment using the temper/grem command. This utilizes LAMMPS partition mode and requires the number of available processors be on the order of the number of desired replicas. A 100-replica simulation would require at least 100 processors (1 per world at minimum). If many replicas are needed on a small number of processors, multi-replica runs can be run outside of LAMMPS. An example of this can be found in examples/PACKAGES/grem and has no limit on the number of replicas per processor. However, this is very inefficient and error prone and should be avoided if possible.

In general, defining the generalized ensembles is unique for every system. When starting a many-replica simulation without any knowledge of the underlying microcanonical temperature, there are several tricks we have utilized to optimize the process. Choosing a less-steep $\eta$ yields broader distributions, requiring fewer replicas to map the microcanonical temperature. While this likely struggles from the same sampling problems gREM was built to avoid, it provides quick insight to Ts. Initially using an evenly-spaced $\lambda$ distribution identifies regions where small changes in enthalpy lead to large temperature changes. Replicas are easily added where needed.

17.65.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The thermo_modify press option is supported by this fix to add the rescaled kinetic pressure as part of thermodynamic output.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the effective temperature $T_{eff}$. The scalar value calculated by this fix is “intensive”.
17.65.5 Restrictions

This fix is part of the REPLICA package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

17.66 fix halt command

17.66.1 Syntax

fix ID group-ID halt N attribute operator avalue keyword value ...

- ID, group-ID are documented in fix command
- halt = style name of this fix command
- N = check halt condition every N steps
- attribute = bondmax or tlimit or v_name
  - bondmax = length of longest bond in the system (in length units)
  - tlimit = elapsed CPU time (in seconds)
  - diskfree = free disk space (in MBytes)
  - v_name = name of equal-style variable
- operator = “<” or “<=” or “>” or “>=” or “==” or “!” or “|”
- avalue = numeric value to compare attribute to
- zero or more keyword/value pairs may be appended
- keyword = error or message or path
  - error value = hard or soft or continue
  - message value = yes or no
  - path value = path to check for free space (may be in quotes)
17.66.2 Examples

```
fix 10 all halt 1 bondmax > 1.5
fix 10 all halt 10 v_myCheck != 0 error soft
fix 10 all halt 100 diskfree < 100000.0 path "dump storage/"
```

17.66.3 Description

Check a condition every N steps during a simulation run. N must be >=1. If the condition is met, exit the run. In this context a “run” can be dynamics or minimization iterations, as specified by the run or minimize command.

The specified group-ID is ignored by this fix.

The specified attribute can be one of the options listed above, namely bondmax, tlimit, diskfree, or an equal-style variable referenced as v_name, where “name” is the name of a variable that has been defined previously in the input script.

The bondmax attribute will loop over all bonds in the system, compute their current lengths, and set attribute to the longest bond distance.

The tlimit attribute queries the elapsed CPU time (in seconds) since the current run began, and sets attribute to that value. This is an alternative way to limit the length of a simulation run, similar to the timer timeout command. There are two differences in using this method versus the timer command option. The first is that the clock starts at the beginning of the current run (not when the timer or fix command is specified), so that any setup time for the run is not included in the elapsed time. The second is that the timer invocation and syncing across all processors (via MPI_Allreduce) is not performed once every N steps by this command. Instead it is performed (typically) only a small number of times and the elapsed times are used to predict when the end-of-the-run will be. Both of these attributes can be useful when performing benchmark calculations for a desired length of time with minimal overhead. For example, if a run is performing 1000s of timesteps/sec, the overhead for syncing the timer frequently across a large number of processors may be non-negligible.

The diskfree attribute will check for available disk space (in MBytes) on supported operating systems. By default it will check the file system of the current working directory. This can be changed with the optional path keyword, which will take the path to a file or folder on the file system to be checked as argument. This path must be given with single or double quotes, if it contains blanks or other special characters (like $).

Equal-style variables evaluate to a numeric value. See the variable command for a description. They calculate formulas which can involve mathematical operations, atom properties, group properties, thermodynamic properties, global values calculated by a compute or fix, or references to other variables. Thus they are a very general means of computing some attribute of the current system. For example, the following “bondmax” variable will calculate the same quantity as the hstyle = bondmax option.

```
compute         bdist all bond/local dist
compute         bmax all reduce max c_bdist
variable        bondmax equal c_bmax
```

Thus these two versions of a fix halt command will do the same thing:

```
fix 10 all halt 1 bondmax > 1.5
fix 10 all halt 1 v_bondmax > 1.5
```

The version with “bondmax” will just run somewhat faster, due to less overhead in computing bond lengths and not storing them in a separate compute.

A variable can be used to implement a large variety of conditions, including to stop when a specific file exists. Example:
variable exit equal is_file(EXIT)
fix 10 all halt 100 v_exit != 0 error soft

Will stop the current run command when a file EXIT is created in the current working directory. The condition can be cleared by removing the file through the shell command.

The choice of operators listed above are the usual comparison operators. The XOR operation (exclusive or) is also included as “|.” In this context, XOR means that if either the attribute or avalue is 0.0 and the other is non-zero, then the result is “true”. Otherwise it is “false”.

The specified avalue must be a numeric value.

The optional error keyword determines how the current run is halted. If its value is hard, then LAMMPS will stop with an error message.

If its value is soft, LAMMPS will exit the current run, but continue to execute subsequent commands in the input script. However, additional run or minimize commands will be skipped. For example, this allows a script to output the current state of the system, e.g. via a write_dump or write_restart command.

If its value is continue, the behavior is the same as for soft, except subsequent run or minimize commands are executed. This allows your script to remedy the condition that triggered the halt, if necessary. Note that you may wish use the unfix command on the fix halt ID, so that the same condition is not immediately triggered in a subsequent run.

The optional message keyword determines whether a message is printed to the screen and logfile when the halt condition is triggered. If message is set to yes, a one line message with the values that triggered the halt is printed. If message is set to no, no message is printed; the run simply exits. The latter may be desirable for post-processing tools that extract thermodynamic information from log files.

17.66.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command.

17.66.5 Restrictions

The diskfree attribute is currently only supported on Linux, MacOSX, and BSD.

</tr>
</tbody>
</table>

17.67.2 Examples

```plaintext
fix 3 qin heat 1 1.0
fix 3 qin heat 10 v_flux
fix 4 qout heat 1 -1.0 region top
```

17.67.3 Description

Add non-translational kinetic energy (heat) to a group of atoms in a manner that conserves their aggregate momentum. Two of these fixes can be used to establish a temperature gradient across a simulation domain by adding heat (energy) to one group of atoms (hot reservoir) and subtracting heat from another (cold reservoir). E.g. a simulation sampling from the McDLT ensemble.

If the region keyword is used, the atom must be in both the group and the specified geometric region in order to have energy added or subtracted to it. If not specified, then the atoms in the group are affected wherever they may move to.

Heat addition/subtraction is performed every N timesteps.

The eflux parameter can be specified as a numeric constant or as an equal- or atom-style variable. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its current value(s) used to determine the flux.

If eflux is a numeric constant or equal-style variable which evaluates to a scalar value, then eflux determines the change in aggregate energy of the entire group of atoms per unit time, e.g. in eV/ps for metal units. In this case it is an “extensive” quantity, meaning its magnitude should be scaled with the number of atoms in the group. Note that since eflux also has per-time units (i.e. it is a flux), this means that a larger value of N will add/subtract a larger amount of energy each time the fix is invoked.

**Note:** The heat-exchange (HEX) algorithm implemented by this fix is known to exhibit a pronounced energy drift. An improved algorithm (eHEX) is available as a fix ehex command and might be preferable if energy conservation is important.
If $eflux$ is specified as an atom-style variable (see below), then the variable computes one value per atom. In this case, each value is the energy flux for a single atom, again in units of energy per unit time. In this case, each value is an “intensive” quantity, which need not be scaled with the number of atoms in the group.

Equal-style variables can specify formulas with various mathematical functions, and include `thermo_style` command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent flux.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus it is easy to specify a spatially-dependent flux with optional time-dependence as well.

**Note:** If heat is subtracted from the system too aggressively so that the group’s kinetic energy would go to zero, or any individual atom’s kinetic energy would go to zero for the case where $eflux$ is an atom-style variable, then LAMMPS will halt with an error message.

Fix heat is different from a thermostat such as `fix nvt` or `fix temp/rescale` in that energy is added/subtracted continually. Thus if there is not another mechanism in place to counterbalance this effect, the entire system will heat or cool continuously. You can use multiple heat fixes so that the net energy change is 0.0 or use `fix viscous` to drain energy from the system.

This fix does not change the coordinates of its atoms; it only scales their velocities. Thus you must still use an integration fix (e.g. `fix nve`) on the affected atoms. This fix should not normally be used on atoms that have their temperature controlled by another fix - e.g. `fix nvt` or `fix langevin` fix.

### 17.67.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the `fix_modify` options are relevant to this fix.

This fix computes a global scalar which can be accessed by various `output` commands. This scalar is the most recent value by which velocities were scaled. The scalar value calculated by this fix is “intensive”. If $eflux$ is specified as an atom-style variable, this fix computes the average value by which the velocities were scaled for all of the atoms that had their velocities scaled.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during energy minimization.

17.68 fix hyper/global command

17.68.1 Syntax

```
fix ID group-ID hyper/global cutbond qfactor Vmax Tequil
```

- ID, group-ID are documented in fix command
- hyper/global = style name of this fix command
- cutbond = max distance at which a pair of atoms is considered bonded (distance units)
- qfactor = max strain at which bias potential goes to 0.0 (unitless)
- Vmax = height of bias potential (energy units)
- Tequil = equilibration temperature (temperature units)

17.68.2 Examples

```
fix 1 all hyper/global 1.0 0.3 0.8 300.0
```

17.68.3 Description

This fix is meant to be used with the hyper command to perform a bond-boost global hyperdynamics (GHD) simulation. The role of this fix is to select a single pair of atoms in the system at each timestep to add a global bias potential to, which will alter the dynamics of the system in a manner that effectively accelerates time. This is in contrast to the fix hyper/local command, which can be used to perform a local hyperdynamics (LHD) simulation, by adding a local bias potential to multiple pairs of atoms at each timestep. GHD can time accelerate a small simulation with up to a few 100 atoms. For larger systems, LHD is needed to achieve good time acceleration.

For a system that undergoes rare transition events, where one or more atoms move over an energy barrier to a new potential energy basin, the effect of the bias potential is to induce more rapid transitions. This can lead to a dramatic speed-up in the rate at which events occur, without altering their relative frequencies, thus leading to an overall increase in the elapsed real time of the simulation as compared to running for the same number of timesteps with normal MD. See the hyper page for a more general discussion of hyperdynamics and citations that explain both GHD and LHD.

The equations and logic used by this fix and described here to perform GHD follow the description given in (Voter2013). The bond-boost form of a bias potential for HD is due to Miron and Fichthorn as described in (Miron). In LAMMPS we use a simplified version of bond-boost GHD where a single bond in the system is biased at any one timestep.

Bonds are defined between each pair of atoms $ij$, whose $R_{ij}^0$ distance is less than cutbond, when the system is in a quenched state (minimum) energy. Note that these are not “bonds” in a covalent sense. A bond is simply any pair of atoms that meet the distance criterion. Cutbond is an argument to this fix; it is discussed below. A bond is only formed if one or both of the $ij$ atoms are in the specified group.

The current strain of bond $ij$ (when running dynamics) is defined as

$$E_{ij} = \frac{R_{ij} - R_{ij}^0}{R_{ij}^0}$$
where $R_{ij}$ is the current distance between atoms $i$ and $j$, and $R_{ij}^{0}$ is the equilibrium distance in the quenched state.

The bias energy $V_{ij}$ of any bond between atoms $i$ and $j$ is defined as

$$
V_{ij} = V^\text{max} \cdot \left(1 - \left(\frac{E_{ij}}{q}\right)^2\right) \text{ for } |E_{ij}| < q\text{factor or 0 otherwise}
$$

where the prefactor $V^\text{max}$ and the cutoff $q\text{factor}$ are arguments to this fix; they are discussed below. This functional form is an inverse parabola centered at 0.0 with height $V^\text{max}$ and which goes to 0.0 at +/- $q\text{factor}$.

Let $E^\text{max}$ be the maximum of $|E_{ij}|$ for all $ij$ bonds in the system on a given timestep. On that step, $V_{ij}$ is added as a bias potential to only the single bond with strain $E^\text{max}$, call it $V_{ij}^\text{max}$. Note that $V_{ij}^\text{max}$ will be 0.0 if $E^\text{max} >= q\text{factor}$ on that timestep. Also note that $V_{ij}^\text{max}$ is added to the normal interatomic potential that is computed between all atoms in the system at every step.

The derivative of $V_{ij}^\text{max}$ with respect to the position of each atom in the $E^\text{max}$ bond gives a bias force $F_{ij}^\text{max}$ acting on the bond as

$$
F_{ij}^\text{max} = -\frac{dV_{ij}^\text{max}}{dE_{ij}} = \frac{2V^\text{max} E_{ij} - ij}{q\text{factor}^2} \text{ for } |E_{ij}| < q\text{factor or 0 otherwise}
$$

which can be decomposed into an equal and opposite force acting on only the two $ij$ atoms in the $E^\text{max}$ bond.

The time boost factor for the system is given each timestep $i$ by

$$
B_i = e^\beta \frac{V_{ij}^\text{max}}
$$

where $\beta = \frac{1}{kT_{\text{equil}}}$, and $T_{\text{equil}}$ is the temperature of the system and an argument to this fix. Note that $B_i >= 1$ at every step.

**Note:** To run a GHD simulation, the input script must also use the `fix langevin` command to thermostat the atoms at the same $T_{\text{equil}}$ as specified by this fix, so that the system is running constant-temperature (NVT) dynamics. LAMMPS does not check that this is done.

The elapsed time $t_{\text{hyper}}$ for a GHD simulation running for $N$ timesteps is simply

$$
t_{\text{hyper}} = \sum_{i=1,N} B - i \cdot dt
$$

where $dt$ is the timestep size defined by the `timestep` command. The effective time acceleration due to GHD is thus $t_{\text{hyper}} / N^*dt$, where $N^*dt$ is elapsed time for a normal MD run of $N$ timesteps.

Note that in GHD, the boost factor varies from timestep to timestep. Likewise, which bond has $E^\text{max}$ strain and thus which pair of atoms the bias potential is added to, will also vary from timestep to timestep. This is in contrast to local hyperdynamics (LHD) where the boost factor is an input parameter; see the `fix hyper/local` page for details.

Here is additional information on the input parameters for GHD.

The `cutbond` argument is the cutoff distance for defining bonds between pairs of nearby atoms. A pair of $ij$ atoms in their equilibrium, minimum-energy configuration, which are separated by a distance $R_{ij} < \text{cutbond}$, are flagged as a bonded pair. Setting `cutbond` to be ~25% larger than the nearest-neighbor distance in a crystalline lattice is a typical choice for solids, so that bonds exist only between nearest neighbor pairs.

The `qfactor` argument is the limiting strain at which the bias potential goes to 0.0. It is dimensionless, so a value of 0.3 means a bond distance can be up to 30% larger or 30% smaller than the equilibrium (quenched) $R_{ij}^{0}$ distance and the two atoms in the bond could still experience a non-zero bias force.
If $q_{factor}$ is set too large, then transitions from one energy basin to another are affected because the bias potential is non-zero at the transition state (e.g., saddle point). If $q_{factor}$ is set too small than little boost is achieved because the $E_{ij}$ strain of some bond in the system will (nearly) always exceed $q_{factor}$. A value of 0.3 for $q_{factor}$ is typically reasonable.

The $V_{max}$ argument is the prefactor on the bias potential. Ideally, it should be set to a value slightly less than the smallest barrier height for an event to occur. Otherwise the applied bias potential may be large enough (when added to the interatomic potential) to produce a local energy basin with a maxima in the center. This can produce artificial energy minima in the same basin that trap an atom. Or if $V_{max}$ is even larger, it may induce an atom(s) to rapidly transition to another energy basin. Both cases are “bad dynamics” which violate the assumptions of GHD that guarantee an accelerated time-accurate trajectory of the system.

Note that if $V_{max}$ is set too small, the GHD simulation will run correctly. There will just be fewer events because the hyper time ($t_{hyper}$ equation above) will be shorter.

**Note:** If you have no physical intuition as to the smallest barrier height in your system, a reasonable strategy to determine the largest $V_{max}$ you can use for a GHD model, is to run a sequence of simulations with smaller and smaller $V_{max}$ values, until the event rate does not change (as a function of hyper time).

The $T_{equil}$ argument is the temperature at which the system is simulated; see the comment above about the $fix$ $langevin$ thermostatting. It is also part of the beta term in the exponential factor that determines how much boost is achieved as a function of the bias potential.

In general, the lower the value of $T_{equil}$ and the higher the value of $V_{max}$, the more time boost will be achievable by the GHD algorithm.

### 17.68.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The $fix$ $modify$ $energy$ option is supported by this fix to add the energy of the bias potential to the global potential energy of the system as part of thermodynamic output. The default setting for this fix is $fix$ $modify$ $energy$ no.

This fix computes a global scalar and global vector of length 12, which can be accessed by various output commands. The scalar is the magnitude of the bias potential (energy units) applied on the current timestep. The vector stores the following quantities:

- 1 = boost factor on this step (unitless)
- 2 = max strain $E_{ij}$ of any bond on this step (absolute value, unitless)
- 3 = ID of first atom in the max-strain bond
- 4 = ID of second atom in the max-strain bond
- 5 = average # of bonds/atom on this step
- 6 = fraction of timesteps where the biased bond has bias = 0.0 during this run
- 7 = fraction of timesteps where the biased bond has negative strain during this run
- 8 = max drift distance of any atom during this run (distance units)
- 9 = max bond length during this run (distance units)
- 10 = cumulative hyper time since fix was defined (time units)
- 11 = cumulative count of event timesteps since fix was defined
- 12 = cumulative count of atoms in events since fix was defined
The first 5 quantities are for the current timestep. Quantities 6-9 are for the current hyper run. They are reset each time a new hyper run is performed. Quantities 19-12 are cumulative across multiple runs (since the point in the input script the fix was defined).

For value 8, drift is the distance an atom moves between two quenched states when the second quench determines an event has occurred. Atoms involved in an event will typically move the greatest distance since others typically remain near their original quenched position.

For value 11, events are checked for by the `hyper` command once every `Nevent` timesteps. This value is the count of those timesteps on which one (or more) events was detected. It is NOT the number of distinct events, since more than one event may occur in the same `Nevent` time window.

For value 12, each time the `hyper` command checks for an event, it invokes a compute to flag zero or more atoms as participating in one or more events. E.g. atoms that have displaced more than some distance from the previous quench state. Value 11 is the cumulative count of the number of atoms participating in any of the events that were found.

The scalar and vector values calculated by this fix are all “intensive”.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during energy minimization.

### 17.68.5 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the `Build package` page for more info.

### 17.68.6 Related commands

```

- ID, group-ID are documented in `fix` command
- `hyper/local` = style name of this fix command
- `cutbond` = max distance at which a pair of atoms is considered bonded (distance units)
- `qfactor` = max strain at which bias potential goes to 0.0 (unitless)
- `Vmax` = estimated height of bias potential (energy units)
• Tequil = equilibration temperature (temperature units)
• Dcut = minimum distance between boosted bonds (distance units)
• alpha = boostostat relaxation time (time units)
• Btarget = desired time boost factor (unitless)
• zero or more keyword/value pairs may be appended
• keyword = bound or reset or check/ghost or check/bias
  bound value = Bfrac
    Bfrac = -1 or a value >= 0.0
  reset value = Rfreq
    Rfreq = -1 or 0 or timestep value > 0
  check/ghost values = none
  check/bias values = Nevery error/warn/ignore

17.69.2 Examples

```plaintext
fix 1 all hyper/local 1.0 0.3 0.8 300.0
fix 1 all hyper/local 1.0 0.3 0.8 300.0 bound 0.1 reset 0
```

17.69.3 Description

This fix is meant to be used with the `hyper` command to perform a bond-boost local hyperdynamics (LHD) simulation. The role of this fix is to select multiple pairs of atoms in the system at each timestep to add a local bias potential to, which will alter the dynamics of the system in a manner that effectively accelerates time. This is in contrast to the `fix hyper/global` command, which can be used to perform a global hyperdynamics (GHD) simulation, by adding a global bias potential to a single pair of atoms at each timestep. GHD can time accelerate a small simulation with up to a few hundred atoms. For larger systems, LHD is needed to achieve good time acceleration.

For a system that undergoes rare transition events, where one or more atoms move over an energy barrier to a new potential energy basin, the effect of the bias potential is to induce more rapid transitions. This can lead to a dramatic speed-up in the rate at which events occur, without altering their relative frequencies, thus leading to an overall increase in the elapsed real time of the simulation as compared to running for the same number of timesteps with normal MD. See the `hyper` page for a more general discussion of hyperdynamics and citations that explain both GHD and LHD.

The equations and logic used by this fix and described here to perform LHD follow the description given in (Voter2013). The bond-boost form of a bias potential for HD is due to Miron and Fichthorn as described in (Miron).

To understand this description, you should first read the description of the GHD algorithm on the `fix hyper/global` doc page. This description of LHD builds on the GHD description.

The definition of bonds and $E_{ij}$ are the same for GHD and LHD. The formulas for $V_{ij}^{\text{max}}$ and $F_{ij}^{\text{max}}$ are also the same except for a prefactor $C_{ij}$, explained below.

The bias energy $V_{ij}$ applied to a bond $ij$ with maximum strain is

$$V_{ij}^{\text{max}} = C_{ij} \cdot V^{\text{max}} \cdot \left(1 - \left(\frac{E_{ij}}{q}\right)^2\right) \text{ for } |E_{ij}| < q \text{factor or 0 otherwise}$$

The derivative of $V_{ij}^{\text{max}}$ with respect to the position of each atom in the $ij$ bond gives a bias force $F_{ij}^{\text{max}}$ acting on the bond as

$$F_{ij}^{\text{max}} = -\frac{dV_{ij}^{\text{max}}}{dE_{ij}} = 2C_{ij}V^{\text{max}} \frac{E_{ij}}{q \text{factor}^2} \text{ for } |E_{ij}| < q \text{factor or 0 otherwise}$$
which can be decomposed into an equal and opposite force acting on only the two atoms \(i\) and \(j\) in the \(ij\) bond.

The key difference is that in GHD a bias energy and force is added (on a particular timestep) to only one bond (pair of atoms) in the system, which is the bond with maximum strain \(E_{ij}^\text{max}\).

In LHD, a bias energy and force can be added to multiple bonds separated by the specified \(D\text{cut}\) distance or more. A bond \(ij\) is biased if it is the maximum strain bond within its local “neighborhood”, which is defined as the bond \(ij\) plus any neighbor bonds within a distance \(D\text{cut}\) from \(i\). The “distance” between bond \(ij\) and bond \(kl\) is the minimum distance between any of the \(ik, il, jk,\) and \(jf\) pairs of atoms.

For a large system, multiple bonds will typically meet this requirement, and thus a bias potential \(V_{ij}^\text{max}\) will be applied to many bonds on the same timestep.

In LHD, all bonds store a \(C_{ij}\) prefactor which appears in the \(V_{ij}^\text{max}\) and \(F_{ij}^\text{max}\) equations above. Note that the \(C_{ij}\) parameter scales the strength of the bias energy and forces whenever bond \(ij\) is the maximum strain bond in its neighborhood. \(C_{ij}\) is initialized to 1.0 when a bond between the \(ij\) atoms is first defined. The specified \(B\text{target}\) factor is then used to adjust the \(C_{ij}\) prefactors for each bond every timestep in the following manner.

An instantaneous boost factor \(B_{ij}\) is computed each timestep for each bond, as

\[
B_{ij} = e^{\beta V_{ij}^\text{max}}
\]

where \(V_{ij}^\text{max}\) is the bias energy of the maxstrain bond \(kl\) within bond \(ij\)’s neighborhood, \(\beta = \frac{1}{kT\text{equil}}\), and \(T\text{equil}\) is the temperature of the system and an argument to this fix.

Note: To run an LHD simulation, the input script must also use the \textit{fix langevin} command to thermostat the atoms at the same \textit{Tequil} as specified by this fix, so that the system is running constant-temperature (NVT) dynamics. LAMMPS does not check that this is done.

Note that if \(ij=kl\), then bond \(ij\) is a biased bond on that timestep, otherwise it is not. But regardless, the boost factor \(B_{ij}\) can be thought of an estimate of time boost currently being applied within a local region centered on bond \(ij\). For LHD, we want this to be the specified \(B\text{target}\) value everywhere in the simulation domain.

To accomplish this, if \(B_{ij} < B\text{target}\), the \(C_{ij}\) prefactor for bond \(ij\) is incremented on the current timestep by an amount proportional to the inverse of the specified \(\alpha\) and the difference \((B_{ij} - B\text{target})\). Conversely if \(B_{ij} > B\text{target}\), \(C_{ij}\) is decremented by the same amount. This procedure is termed “boostostatting” in (Voter2013). It drives all of the individual \(C_{ij}\) to values such that when \(V_{ij}^\text{max}\) is applied as a bias to bond \(ij\), the resulting boost factor \(B_{ij}\) will be close to \(B\text{target}\) on average. Thus the LHD time acceleration factor for the overall system is effectively \(B\text{target}\).

Note that in LHD, the boost factor \(B\text{target}\) is specified by the user. This is in contrast to global hyperdynamics (GHD) where the boost factor varies each timestep and is computed as a function of \(V_{\text{max}}, E_{\text{max}},\) and \(T\text{equil}\); see the \textit{fix hyper/global} page for details.

Here is additional information on the input parameters for LHD.

Note that the \textit{cutbond}, \textit{qfactor}, and \textit{Tequil} arguments have the same meaning as for GHD. The \textit{Vmax} argument is slightly different. The \textit{Dcut}, \textit{alpha}, and \textit{Btarget} parameters are unique to LHD.

The \textit{cutbond} argument is the cutoff distance for defining bonds between pairs of nearby atoms. A pair of LJ atoms in their equilibrium, minimum-energy configuration, which are separated by a distance \(R_{ij} < \text{cutbond}\), are flagged as a bonded pair. Setting \textit{cutbond} to be ~25% larger than the nearest-neighbor distance in a crystalline lattice is a typical choice for solids, so that bonds exist only between nearest neighbor pairs.

The \textit{qfactor} argument is the limiting strain at which the bias potential goes to 0.0. It is dimensionless, so a value of 0.3 means a bond distance can be up to 30% larger or 30% smaller than the equilibrium (quenched) \(R_{ij}^\text{eq}\) distance and the two atoms in the bond could still experience a non-zero bias force.
If \texttt{qfactor} is set too large, then transitions from one energy basin to another are affected because the bias potential is non-zero at the transition state (e.g. saddle point). If \texttt{qfactor} is set too small than little boost can be achieved because the \( E_{ij} \) strain of some bond in the system will (nearly) always exceed \texttt{qfactor}. A value of 0.3 for \texttt{qfactor} is typically a reasonable value.

The \texttt{Vmax} argument is a fixed prefactor on the bias potential. There is also a dynamic prefactor \( C_{ij} \), driven by the choice of \texttt{Btarget} as discussed above. The product of these should be a value less than the smallest barrier height for an event to occur. Otherwise the applied bias potential may be large enough (when added to the interatomic potential) to produce a local energy basin with a maxima in the center. This can produce artificial energy minima in the same basin that trap an atom. Or if \( C_{ij} \cdot V_{max} \) is even larger, it may induce an atom(s) to rapidly transition to another energy basin. Both cases are “bad dynamics” which violate the assumptions of LHD that guarantee an accelerated time-accurate trajectory of the system.

\textbf{Note:} It may seem that \( V_{max} \) can be set to any value, and \( C_{ij} \) will compensate to reduce the overall prefactor if necessary. However the \( C_{ij} \) are initialized to 1.0 and the boostostatting procedure typically operates slowly enough that there can be a time period of bad dynamics if \( V_{max} \) is set too large. A better strategy is to set \( V_{max} \) to the slightly smaller than the lowest barrier height for an event (the same as for GHD), so that the \( C_{ij} \) remain near unity.

The \texttt{Tequil} argument is the temperature at which the system is simulated; see the comment above about the \texttt{fix langevin} thermostating. It is also part of the beta term in the exponential factor that determines how much boost is achieved as a function of the bias potential. See the discussion of the \texttt{Btarget} argument below.

As discussed above, the \texttt{Dcut} argument is the distance required between two locally maxstrain bonds for them to both be selected as biased bonds on the same timestep. Computationally, the larger \texttt{Dcut} is, the more work (computation and communication) must be done each timestep within the LHD algorithm. And the fewer bonds can be simultaneously biased, which may mean the specified \texttt{Btarget} time acceleration cannot be achieved.

Physically \texttt{Dcut} should be a long enough distance that biasing two pairs of atoms that close together will not influence the dynamics of each pair. E.g. something like 2x the cutoff of the interatomic potential. In practice a \texttt{Dcut} value of \( \sim 10 \) Angstroms seems to work well for many solid-state systems.

\textbf{Note:} You should insure that ghost atom communication is performed for a distance of at least \( D_{cut} + cutevent \) = the distance one or more atoms move (between quenched states) to be considered an “event”. It is an argument to the “compute event/displace” command used to detect events. By default the ghost communication distance is set by the \texttt{pair_style cutoff}, which will typically be \(< D_{cut} \). The \texttt{comm_modify cutoff} command should be used to override the ghost cutoff explicitly, e.g.

\begin{verbatim}
comm_modify cutoff 12.0
\end{verbatim}

Note that this fix does not know the \texttt{cutevent} parameter, but uses half the \texttt{cutbond} parameter as an estimate to warn if the ghost cutoff is not long enough.

As described above the \texttt{alpha} argument is a prefactor in the boostostat update equation for each bond’s \( C_{ij} \) prefactor. \textit{Alpha} is specified in time units, similar to other thermostat or barostat damping parameters. It is roughly the physical time it will take the boostostat to adjust a \( C_{ij} \) value from a too high (or too low) value to a correct one. An \texttt{alpha} setting of a few ps is typically good for solid-state systems. Note that the \texttt{alpha} argument here is the inverse of the \texttt{alpha} parameter discussed in (Voter2013).

The \texttt{Btarget} argument is the desired time boost factor (a value > 1) that all the atoms in the system will experience. The elapsed time \( t_{hyper} \) for an LHD simulation running for \( N \) timesteps is simply

\[ t_{hyper} = B_{target} \cdot N \cdot dt \]

where \( dt \) is the timestep size defined by the \texttt{timestep} command. The effective time acceleration due to LHD is thus

\[ \frac{t_{hyper}}{N \cdot dt} = B_{target} \], where \( N \cdot dt \) is the elapsed time for a normal MD run of \( N \) timesteps.
You cannot choose an arbitrarily large setting for $B_{\text{target}}$. The maximum value you should choose is

$$B_{\text{target}} = e^{\beta V_{\text{small}}}$$

where $V_{\text{small}}$ is the smallest event barrier height in your system, $\beta = \frac{1}{kT_{\text{equil}}}$, and $T_{\text{equil}}$ is the specified temperature of the system (both by this fix and the Langevin thermostat).

Note that if $B_{\text{target}}$ is set smaller than this, the LHD simulation will run correctly. There will just be fewer events because the hyper time (t_hyper equation above) will be shorter.

**Note:** If you have no physical intuition as to the smallest barrier height in your system, a reasonable strategy to determine the largest $B_{\text{target}}$ you can use for an LHD model, is to run a sequence of simulations with smaller and smaller $B_{\text{target}}$ values, until the event rate does not change (as a function of hyper time).

Here is additional information on the optional keywords for this fix.

The **bound** keyword turns on min/max bounds for bias coefficients $C_{ij}$ for all bonds. $C_{ij}$ is a prefactor for each bond on the bias potential of maximum strength $V_{\text{max}}$. Depending on the choice of alpha and $B_{\text{target}}$ and $V_{\text{max}}$, the boostostatation can cause individual $C_{ij}$ values to fluctuate. If the fluctuations are too large $C_{ij} \cdot V_{\text{max}}$ can exceed low barrier heights and induce bad event dynamics. Bounding the $C_{ij}$ values is a way to prevent this. If $B_{\text{frac}}$ is set to -1 or any negative value (the default) then no bounds are enforced on $C_{ij}$ values (except they must always be $\geq 0.0$). A $B_{\text{frac}}$ setting $\geq 0.0$ sets a lower bound of $1.0 - B_{\text{frac}}$ and upper bound of $1.0 + B_{\text{frac}}$ on each $C_{ij}$ value. Note that all $C_{ij}$ values are initialized to 1.0 when a bond is created for the first time. Thus $B_{\text{frac}}$ limits the bias potential height to $V_{\text{max}} \pm B_{\text{frac}} \cdot V_{\text{max}}$.

The **reset** keyword allows $V_{\text{max}}$ to be adjusted dynamically depending on the average value of all $C_{ij}$ prefactors. This can be useful if you are unsure what value of $V_{\text{max}}$ will match the $B_{\text{target}}$ boost for the system. The $C_{ij}$ values will then adjust in aggregate (up or down) so that $C_{ij} \cdot V_{\text{max}}$ produces a boost of $B_{\text{target}}$, but this may conflict with the **bound** keyword settings. By using **bound** and **reset** together, $V_{\text{max}}$ itself can be reset, and desired bounds still applied to the $C_{ij}$ values.

A setting for $R_{\text{freq}}$ of -1 (the default) means $V_{\text{max}}$ never changes. A setting of 0 means $V_{\text{max}}$ is adjusted every time an event occurs and bond pairs are recalculated. A setting of $N > 0$ timesteps means $V_{\text{max}}$ is adjusted on the first time an event occurs on a timestep $\geq N$ steps after the previous adjustment. The adjustment to $V_{\text{max}}$ is computed as follows. The current average of all $C_{ij} \cdot V_{\text{max}}$ values is computed and the $V_{\text{max}}$ is reset to that value. All $C_{ij}$ values are changed to new prefactors such the new $C_{ij} \cdot V_{\text{max}}$ is the same as it was previously. If the **bound** keyword was used, those bounds are enforced on the new $C_{ij}$ values. Henceforth, new bonds are assigned a $C_{ij} = 1.0$, which means their bias potential magnitude is the new $V_{\text{max}}$.

The **check/ghost** keyword turns on extra computation each timestep to compute statistics about ghost atoms used to determine which bonds to bias. The output of these stats are the vector values 14 and 15, described below. If this keyword is not enabled, the output of the stats will be zero.

The **check/bias** keyword turns on extra computation and communication to check if any biased bonds are closer than $D_{\text{cut}}$ to each other, which should not be the case if LHD is operating correctly. Thus it is a debugging check. The $Nevery$ setting determines how often the check is made. The $error$, $warn$, or $ignore$ setting determines what is done if the count of too-close bonds is not zero. Either the code will exit, or issue a warning, or silently tally the count. The count can be output as vector value 17, as described below. If this keyword is not enabled, the output of that statistic will be 0.

Note that both of these computations are costly, hence they are only enabled by these keywords.
17.69.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify energy option is supported by this fix to add the energy of the bias potential to the global potential energy of the system as part of thermodynamic output. The default setting for this fix is fix_modify energy no.

This fix computes a global scalar and global vector of length 28, which can be accessed by various output commands. The scalar is the magnitude of the bias potential (energy units) applied on the current timestep, summed over all biased bonds. The vector stores the following quantities:

- 1 = average boost for all bonds on this step (unitless)
- 2 = # of biased bonds on this step
- 3 = max strain $E_{ij}$ of any bond on this step (absolute value, unitless)
- 4 = value of $V_{max}$ on this step (energy units)
- 5 = average bias coeff for all bonds on this step (unitless)
- 6 = min bias coeff for all bonds on this step (unitless)
- 7 = max bias coeff for all bonds on this step (unitless)
- 8 = average # of bonds/atom on this step
- 9 = average neighbor bonds/bond on this step within $D_{cut}$
- 10 = average boost for all bonds during this run (unitless)
- 11 = average # of biased bonds/step during this run
- 12 = fraction of biased bonds with no bias during this run
- 13 = fraction of biased bonds with negative strain during this run
- 14 = max bond length during this run (distance units)
- 15 = average bias coeff for all bonds during this run (unitless)
- 16 = min bias coeff for any bond during this run (unitless)
- 17 = max bias coeff for any bond during this run (unitless)
- 18 = max drift distance of any bond atom during this run (distance units)
- 19 = max distance from proc subbox of any ghost atom with maxstrain < qfactor during this run (distance units)
- 20 = max distance outside my box of any ghost atom with any maxstrain during this run (distance units)
- 21 = count of ghost atoms that could not be found on reneighbor steps during this run
- 22 = count of bias overlaps (< $D_{cut}$) found during this run
- 23 = cumulative hyper time since fix created (time units)
- 24 = cumulative count of event timesteps since fix created
- 25 = cumulative count of atoms in events since fix created
- 26 = cumulative # of new bonds formed since fix created
- 27 = average boost for biased bonds on this step (unitless)
- 28 = # of bonds with absolute strain $>= q$ on this step

The first quantities 1-9 are for the current timestep. Quantities 10-22 are for the current hyper run. They are reset each time a new hyper run is performed. Quantities 23-26 are cumulative across multiple runs (since the point in the input script the fix was defined).
For value 10, each bond instantaneous boost factor is given by the equation for $B_{ij}$ above. The total system boost (average across all bonds) fluctuates, but should average to a value close to the specified $B_{\text{target}}$.

For value 12, the numerator is a count of all biased bonds on each timestep whose bias energy = 0.0 due to $E_{ij} >= q_{factor}$. The denominator is the count of all biased bonds on all timesteps.

For value 13, the numerator is a count of all biased bonds on each timestep with negative strain. The denominator is the count of all biased bonds on all timesteps.

Values 18-22 are mostly useful for debugging and diagnostic purposes.

For value 18, drift is the distance an atom moves between two quenched states when the second quench determines an event has occurred. Atoms involved in an event will typically move the greatest distance since others typically remain near their original quenched position.

For values 19-21, neighbor atoms in the full neighbor list with cutoff $D_{\text{cut}}$ may be ghost atoms outside a processor’s sub-box. Before the next event occurs they may move further than $D_{\text{cut}}$ away from the sub-box boundary. Value 19 is the furthest (from the sub-box) any ghost atom in the neighbor list with maxstrain < $q_{factor}$ was accessed during the run. Value 20 is the same except that the ghost atom’s maxstrain may be $>= q_{factor}$, which may mean it is about to participate in an event. Value 21 is a count of how many ghost atoms could not be found on reneighbor steps, presumably because they moved too far away due to their participation in an event (which will likely be detected at the next quench).

Typical values for 19 and 20 should be slightly larger than $D_{\text{cut}}$, which accounts for ghost atoms initially at a $D_{\text{cut}}$ distance moving thermally before the next event takes place.

Note that for values 19 and 20 to be computed, the optional keyword check/ghost must be specified. Otherwise these values will be zero. This is because computing them incurs overhead, so the values are only computed if requested.

Value 21 should be zero or small. As explained above a small count likely means some ghost atoms were participating in their own events and moved a longer distance. If the value is large, it likely means the communication cutoff for ghosts is too close to $D_{\text{cut}}$ leading to many not-found ghost atoms before the next event. This may lead to a reduced number of bonds being selected for biasing, since the code assumes those atoms are part of highly strained bonds. As explained above, the comm_modify cutoff command can be used to set a longer cutoff.

For value 22, no two bonds should be biased if they are within a $D_{\text{cut}}$ distance of each other. This value should be zero, indicating that no pair of biased bonds are closer than $D_{\text{cut}}$ from each other.

Note that for value 22 to be computed, the optional keyword check/bias must be specified and it determines how often this check is performed. This is because performing the check incurs overhead, so if only computed as often as requested.

The result at the end of the run is the cumulative total from every timestep the check was made. Note that the value is a count of atoms in bonds which found other atoms in bonds too close, so it is almost always an over-count of the number of too-close bonds.

Value 23 is simply the specified boost factor times the number of timesteps times the timestep size.

For value 24, events are checked for by the hyper command once every $N_{\text{event}}$ timesteps. This value is the count of those timesteps on which one (or more) events was detected. It is NOT the number of distinct events, since more than one event may occur in the same $N_{\text{event}}$ time window.

For value 25, each time the hyper command checks for an event, it invokes a compute to flag zero or more atoms as participating in one or more events. E.g. atoms that have displaced more than some distance from the previous quench state. Value 25 is the cumulative count of the number of atoms participating in any of the events that were found.

Value 26 tallies the number of new bonds created by the bond reset operation. Bonds between a specific I,J pair of atoms may persist for the entire hyperdynamics simulation if neither I or J are involved in an event.

Value 27 computes the average boost for biased bonds only on this step.

Value 28 is the count of bonds with an absolute value of strain $>= q$ on this step.
The scalar value is an “extensive” quantity since it grows with the system size; the vector values are all “intensive”. This fix also computes a local vector of length the number of bonds currently in the system. The value for each bond is its $C_{ij}$ prefactor (bias coefficient). These values can be can be accessed by various *output commands*. A particularly useful one is the *fix ave/histo* command which can be used to histogram the $C_{ij}$ values to see if they are distributed reasonably close to 1.0, which indicates a good choice of $V_{\text{max}}$.

The local values calculated by this fix are unitless.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

### 17.69.5 Restrictions

This fix is part of the REPLICA package. It is only enabled if LAMMPS was built with that package. See the *Build package* doc page for more info.

### 17.69.6 Related commands

*hyper, fix hyper/global*

### 17.69.7 Default

The default settings for optimal keywords are bounds = -1 and reset = -1. The check/ghost and check/bias keywords are not enabled by default.

### 17.70 fix imd command

#### 17.70.1 Syntax

```plaintext
fix ID group-ID imd trate port keyword values ...
```

- ID, group-ID are documented in *fix* command
- imd = style name of this fix command
- port = port number on which the fix listens for an IMD client
- keyword = *unwrap* or *fscale* or *trate*
  - *unwrap* arg = on or off
    - off = coordinates are wrapped back into the principal unit cell (default)
    - on = "unwrapped" coordinates using the image flags used
  - *fscale* arg = factor
    - factor = floating point number to scale IMD forces (default: 1.0)
  - *trate* arg = transmission rate of coordinate data sets (default: 1)
  - *nowait* arg = on or off
    - off = LAMMPS waits to be connected to an IMD client before continuing (default)
    - on = LAMMPS listens for an IMD client, but continues with the run
17.70.2 Examples

```
fix vmd all imd 5678
fix comm all imd 8888 trate 5 unwrap on fscale 10.0
```

17.70.3 Description

This fix implements the “Interactive MD” (IMD) protocol which allows realtime visualization and manipulation of MD simulations through the IMD protocol, as initially implemented in VMD and NAMD. Specifically it allows LAMMPS to connect an IMD client, for example the VMD visualization program, so that it can monitor the progress of the simulation and interactively apply forces to selected atoms.

If LAMMPS is compiled with the pre-processor flag -DLAMMPS_ASYNC_IMD then fix imd will use POSIX threads to spawn a IMD communication thread on MPI rank 0 in order to offload data reading and writing from the main execution thread and potentially lower the inferred latencies for slow communication links. This feature has only been tested under linux.

There are example scripts for using this package with LAMMPS in examples/PACKAGES/imd. Additional examples and a driver for use with the Novint Falcon game controller as haptic device can be found at: http://sites.google.com/site/akohlmey/software/vrpn-icms.

The source code for this fix includes code developed by the Theoretical and Computational Biophysics Group in the Beckman Institute for Advanced Science and Technology at the University of Illinois at Urbana-Champaign. We thank them for providing a software interface that allows codes like LAMMPS to hook to VMD.

Upon initialization of the fix, it will open a communication port on the node with MPI task 0 and wait for an incoming connection. As soon as an IMD client is connected, the simulation will continue and the fix will send the current coordinates of the fix’s group to the IMD client at every trate MD step. When using r-RESPA, trate applies to the steps of the outmost RESPA level. During a run with an active IMD connection also the IMD client can request to apply forces to selected atoms of the fix group.

The port number selected must be an available network port number. On many machines, port numbers < 1024 are reserved for accounts with system manager privilege and specific applications. If multiple imd fixes would be active at the same time, each needs to use a different port number.

The `nowait` keyword controls the behavior of the fix when no IMD client is connected. With the default setting of `off`, LAMMPS will wait until a connection is made before continuing with the execution. Setting `nowait` to `on` will have the LAMMPS code be ready to connect to a client, but continue with the simulation. This can for example be used to monitor the progress of an ongoing calculation without the need to be permanently connected or having to download a trajectory file.

The `trate` keyword allows to select how often the coordinate data is sent to the IMD client. It can also be changed on request of the IMD client through an IMD protocol message. The `unwrap` keyword allows to send “unwrapped” coordinates to the IMD client that undo the wrapping back of coordinates into the principle unit cell, as done by default in LAMMPS. The `fscale` keyword allows to apply a scaling factor to forces transmitted by the IMD client. The IMD protocols stipulates that forces are transferred in kcal/mol/angstrom under the assumption that coordinates are given in angstrom. For LAMMPS runs with different units or as a measure to tweak the forces generated by the manipulation of the IMD client, this option allows to make adjustments.

To connect VMD to a listening LAMMPS simulation on the same machine with fix imd enabled, one needs to start VMD and load a coordinate or topology file that matches the fix group. When the VMD command prompts appears, one types the command line:

```
imd connect localhost 5678
```

This assumes that `fix imd` was started with 5678 as a port number for the IMD protocol.

17.70. `fix imd command`
The steps to do interactive manipulation of a running simulation in VMD are the following:

In the Mouse menu of the VMD Main window, select “Mouse -> Force -> Atom”. You may alternately select “Residue”, or “Fragment” to apply forces to whole residues or fragments. Your mouse can now be used to apply forces to your simulation. Click on an atom, residue, or fragment and drag to apply a force. Click quickly without moving the mouse to turn the force off. You can also use a variety of 3D position trackers to apply forces to your simulation. Game controllers or haptic devices with force-feedback such as the Novint Falcon or Sensable PHANTOM allow you to feel the resistance due to inertia or interactions with neighbors that the atoms experience you are trying to move, as if they were real objects. See the VMD IMD Homepage and the VRPN-ICMS Homepage for more details.

If IMD control messages are received, a line of text describing the message and its effect will be printed to the LAMMPS output screen, if screen output is active.

**17.70.4 Restart, fix_modify, output, run start/stop, minimize info**

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global scalar or vector or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

**17.70.5 Restrictions**

This fix is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

When used in combination with VMD, a topology or coordinate file has to be loaded, which matches (in number and ordering of atoms) the group the fix is applied to. The fix internally sorts atom IDs by ascending integer value; in VMD (and thus the IMD protocol) those will be assigned 0-based consecutive index numbers.

When using multiple active IMD connections at the same time, each needs to use a different port number.

**17.71 fix indent command**

**17.71.1 Syntax**

```
fix ID group-ID indent K keyword values ...
```

- ID, group-ID are documented in fix command
- indent = style name of this fix command
- K = force constant for indenter surface (force/distance^2 units)
- one or more keyword/value pairs may be appended
• keyword = sphere or cylinder or plane or side or units

sphere args = x y z R  
x, y, z = initial position of center of indenter (distance units)  
R = sphere radius of indenter (distance units)  
any of x, y, z, R can be a variable (see below)

cylinder args = dim c1 c2 R  
dim = x or y or z = axis of cylinder  
c1, c2 = coords of cylinder axis in other 2 dimensions (distance units)  
R = cylinder radius of indenter (distance units)  
any of c1, c2, R can be a variable (see below)

plane args = dim pos side  
dim = x or y or z = plane perpendicular to this dimension  
pos = position of plane in dimension x, y, or z (distance units)  
pos can be a variable (see below)  
side = lo or hi

side value = in or out  
in = the indenter acts on particles inside the sphere or cylinder  
out = the indenter acts on particles outside the sphere or cylinder

units value = lattice or box  
lattice = the geometry is defined in lattice units  
box = the geometry is defined in simulation box units

17.71.2 Examples

```bash
fix 1 all indent 10.0 sphere 0.0 0.0 15.0 3.0
fix 1 all indent 10.0 sphere v_x v_y 0.0 v_radius side in
fix 2 flow indent 10.0 cylinder z 0.0 0.0 10.0 units box
```

17.71.3 Description

Insert an indenter within a simulation box. The indenter repels all atoms in the group that touch it, so it can be used to push into a material or as an obstacle in a flow. Or it can be used as a constraining wall around a simulation; see the discussion of the side keyword below.

The indenter can either be spherical or cylindrical or planar. You must set one of those 3 keywords.

A spherical indenter exerts a force of magnitude

\[ F(r) = -K (r - R)^2 \]

on each atom where \( K \) is the specified force constant, \( r \) is the distance from the atom to the center of the indenter, and \( R \) is the radius of the indenter. The force is repulsive and \( F(r) = 0 \) for \( r > R \).

A cylindrical indenter exerts the same force, except that \( r \) is the distance from the atom to the center axis of the cylinder. The cylinder extends infinitely along its axis.

Spherical and cylindrical indenters account for periodic boundaries in two ways. First, the center point of a spherical indenter \((x, y, z)\) or axis of a cylindrical indenter \((c1, c2)\) is remapped back into the simulation box, if the box is periodic in a particular dimension. This occurs every timestep if the indenter geometry is specified with a variable (see below), e.g. it is moving over time. Second, the calculation of distance to the indenter center or axis accounts for periodic boundaries. Both of these mean that an indenter can effectively move through and straddle one or more periodic boundaries.
A planar indenter is really an axis-aligned infinite-extent wall exerting the same force on atoms in the system, where \( R \) is the position of the plane and \( r-R \) is the distance from the plane. If the side parameter of the plane is specified as lo then it will indent from the lo end of the simulation box, meaning that atoms with a coordinate less than the plane’s current position will be pushed towards the hi end of the box and atoms with a coordinate higher than the plane’s current position will feel no force. Vice versa if side is specified as hi.

Any of the 4 quantities defining a spherical indenter’s geometry can be specified as an equal-style variable, namely \( x \), \( y \), \( z \), or \( R \). Similarly, for a cylindrical indenter, any of \( c1 \), \( c2 \), or \( R \), can be a variable. For a planar indenter, pos can be a variable. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to define the indenter geometry.

Note that equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify indenter properties that change as a function of time or span consecutive runs in a continuous fashion. For the latter, see the start and stop keywords of the run command and the elaplong keyword of thermo_style custom for details.

For example, if a spherical indenter’s x-position is specified as v_x, then this variable definition will keep it’s center at a relative position in the simulation box, 1/4 of the way from the left edge to the right edge, even if the box size changes:

```plaintext
variable x equal "xlo + 0.25*lx"
```

Similarly, either of these variable definitions will move the indenter from an initial position at 2.5 at a constant velocity of 5:

```plaintext
variable x equal "2.5 + 5*elaplong*dt"
variable x equal vdisplace(2.5,5)
```

If a spherical indenter’s radius is specified as v_r, then these variable definitions will grow the size of the indenter at a specified rate.

```plaintext
variable r0 equal 0.0
variable rate equal 1.0
variable r equal "v_r0 + step*dt*v_rate"
```

If the side keyword is specified as out, which is the default, then particles outside the indenter are pushed away from its outer surface, as described above. This only applies to spherical or cylindrical indenters. If the side keyword is specified as in, the action of the indenter is reversed. Particles inside the indenter are pushed away from its inner surface. In other words, the indenter is now a containing wall that traps the particles inside it. If the radius shrinks over time, it will squeeze the particles.

The units keyword determines the meaning of the distance units used to define the indenter geometry. A box value selects standard distance units as defined by the units command, e.g. Angstroms for units = real or metal. A lattice value means the distance units are in lattice spacings. The lattice command must have been previously used to define the lattice spacing. The (x,y,z) coords of the indenter position are scaled by the x,y,z lattice spacings respectively. The radius of a spherical or cylindrical indenter is scaled by the x lattice spacing.

Note that the units keyword only affects indenter geometry parameters specified directly with numbers, not those specified as variables. In the latter case, you should use the xlat, ylat, zlat keywords of the thermo_style command if you want to include lattice spacings in a variable formula.

The force constant \( K \) is not affected by the units keyword. It is always in force/distance^2 units where force and distance are defined by the units command. If you wish K to be scaled by the lattice spacing, you can define K with a variable whose formula contains xlat, ylat, zlat keywords of the thermo_style command, e.g.

```plaintext
variable k equal 100.0/xlat/xlat
fix 1 all indent $k sphere ...
```
17.71.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify energy option is supported by this fix to add the energy of interaction between atoms and the indenter to the global potential energy of the system as part of thermodynamic output. The default setting for this fix is fix_modify energy no. The energy of each particle interacting with the indenter is $K/3 (r - R)^3$.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar energy and a global 3-vector of forces (on the indenter), which can be accessed by various output commands. The scalar and vector values calculated by this fix are “extensive”.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command. Note that if you define the indenter geometry with a variable using a time-dependent formula, LAMMPS uses the iteration count in the minimizer as the timestep. But it is almost certainly a bad idea to have the indenter change its position or size during a minimization. LAMMPS does not check if you have done this.

Note: If you want the atom/indenter interaction energy to be included in the total potential energy of the system (the quantity being minimized), you must enable the fix_modify energy option for this fix.

17.71.5 Restrictions

17.71.7 Default

The option defaults are side = out and units = lattice.

17.72 fix ipi command

17.72.1 Syntax

```
fix ID group-ID ipi address port [unix] [reset]
```

- ID, group-ID are documented in fix command
- ipi = style name of this fix command
- address = internet address (FQDN or IP), or UNIX socket name
- port = port number (ignored for UNIX sockets)
- optional keyword = unix, if present uses a unix socket
- optional keyword = reset, if present reset electrostatics at each call
17.72.2 Examples

```
fix 1 all ipi my.server.com 12345
fix 1 all ipi mysocket 666 unix reset
```

17.72.3 Description

This fix enables LAMMPS to be run as a client for the i-PI Python wrapper (IPI) for performing a path integral molecular dynamics (PIMD) simulation. The philosophy behind i-PI is described in the following publication (IPI-CPC).

A version of the i-PI package, containing only files needed for use with LAMMPS, is provided in the tools/i-pi directory. See the tools/i-pi/manual.pdf for an introduction to i-PI. The examples/PACKAGES/i-pi directory contains example scripts for using i-PI with LAMMPS.

In brief, the path integral molecular dynamics is performed by the Python wrapper, while the client (LAMMPS in this case) simply computes forces and energy for each configuration. The communication between the two components takes place using sockets, and is reduced to the bare minimum. All the parameters of the dynamics are specified in the input of i-PI, and all the parameters of the force field must be specified as LAMMPS inputs, preceding the fix ipi command.

The server address must be specified by the address argument, and can be either the IP address, the fully-qualified name of the server, or the name of a UNIX socket for local, faster communication. In the case of internet sockets, the port argument specifies the port number on which i-PI is listening, while the unix optional switch specifies that the socket is a UNIX socket.

Note that there is no check of data integrity, or that the atomic configurations make sense. It is assumed that the species in the i-PI input are listed in the same order as in the data file of LAMMPS. The initial configuration is ignored, as it will be substituted with the coordinates received from i-PI before forces are ever evaluated.

A note of caution when using potentials that contain long-range electrostatics, or that contain parameters that depend on box size: all of these options will be initialized based on the cell size in the LAMMPS-side initial configuration and kept constant during the run. This is required to e.g. obtain reproducible and conserved forces. If the cell varies too wildly, it may be advisable to re-initialize these interactions at each call. This behavior can be requested by setting the reset switch.

17.72.4 Restart, fix_modify, output, run start/stop, minimize info

There is no restart information associated with this fix, since all the dynamical parameters are dealt with by i-PI.

17.72.5 Restrictions

Using this fix on anything other than all atoms requires particular care, since i-PI will know nothing on atoms that are not those whose coordinates are transferred. However, one could use this strategy to define an external potential acting on the atoms that are moved by i-PI.

This fix is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info. Because of the use of UNIX domain sockets, this fix will only work in a UNIX environment.

17.73.3 Description

Apply a Langevin thermostat as described in [Schneider] to a group of atoms which models an interaction with a background implicit solvent. Used with fix nve, this command performs Brownian dynamics (BD), since the total force on each atom will have the form:

\[ F = F_c + F_f + F_r \]

\[ F_f = -\frac{m}{\text{damp}} v \]

\[ F_r \propto \sqrt{\frac{k_B T m}{\text{dt damp}}} \]

\( F_c \) is the conservative force computed via the usual inter-particle interactions (pair_style, bond_style, etc). The \( F_f \) and \( F_r \) terms are added by this fix on a per-particle basis. See the pair_style dpd/tstat command for a thermostatting option that adds similar terms on a pairwise basis to pairs of interacting particles.

\( F_f \) is a frictional drag or viscous damping term proportional to the particle’s velocity. The proportionality constant for each atom is computed as \( \frac{m}{\text{damp}} \), where \( m \) is the mass of the particle and damp is the damping factor specified by the user.

\( F_r \) is a force due to solvent atoms at a temperature \( T \) randomly bumping into the particle. As derived from the fluctuation/dissipation theorem, its magnitude as shown above is proportional to \( \sqrt{\frac{k_B T m}{\text{dt damp}}} \), where \( k_B \) is the Boltzmann constant, \( T \) is the desired temperature, \( m \) is the mass of the particle, \( \text{dt} \) is the timestep size, and damp is the damping factor. Random numbers are used to randomize the direction and magnitude of this force as described in [Dunweg], where a uniform random number is used (instead of a Gaussian random number) for speed.

Note that unless you use the omega or angmom keywords, the thermostat effect of this fix is applied to only the translational degrees of freedom for the particles, which is an important consideration for finite-size particles, which have rotational degrees of freedom, are being thermostatted. The translational degrees of freedom can also have a bias velocity removed from them before thermostatting takes place; see the description below.

Note: Unlike the fix nvt command which performs Nose/Hoover thermostatting AND time integration, this fix does NOT perform time integration. It only modifies forces to effect thermostatting. Thus you must use a separate time integration fix, like fix nve to actually update the velocities and positions of atoms using the modified forces. Likewise, this fix should not normally be used on atoms that also have their temperature controlled by another fix - e.g. by fix nvt or fix temp/rescale commands.

See the Howto thermostat page for a discussion of different ways to compute temperature and perform thermostatting. The desired temperature at each timestep is a ramped value during the run from \( T_{\text{start}} \) to \( T_{\text{stop}} \).

\( T_{\text{start}} \) can be specified as an equal-style or atom-style variable. In this case, the \( T_{\text{stop}} \) setting is ignored. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the target temperature.

Equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent temperature.
Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus it is easy to specify a spatially-dependent temperature with optional time-dependence as well.

Like other fixes that perform thermostatting, this fix can be used with compute commands that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial region, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the fix_modify command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual compute temp commands to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

The damp parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 100.0 means to relax the temperature in a timespan of (roughly) 100 time units (τ or fs or ps - see the units command). The damp factor can be thought of as inversely related to the viscosity of the solvent. I.e. a small relaxation time implies a high-viscosity solvent and vice versa. See the discussion about γ and viscosity in the documentation for the fix viscous command for more details.

The random seed must be a positive integer. A Marsaglia random number generator is used. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.

The keyword/value option pairs are used in the following ways.

The keyword angmom and omega keywords enable thermostatting of rotational degrees of freedom in addition to the usual translational degrees of freedom. This can only be done for finite-size particles.

A simulation using atom_style sphere defines an omega for finite-size spheres. A simulation using atom_style ellipsoid defines a finite size and shape for aspherical particles and an angular momentum. The Langevin formulas for thermostatting the rotational degrees of freedom are the same as those above, where force is replaced by torque, m is replaced by the moment of inertia I, and v is replaced by omega (which is derived from the angular momentum in the case of aspherical particles).

The rotational temperature of the particles can be monitored by the compute temp/sphere and compute temp/asphere commands with their rotate options.

For the omega keyword there is also a scale factor of 10.0/3.0 that is applied as a multiplier on the $F_f$ (damping) term in the equation above and of $\sqrt{10.0/3.0}$ as a multiplier on the $F_r$ term. This does not affect the thermostatting behavior of the Langevin formalism but insures that the randomized rotational diffusivity of spherical particles is correct.

For the angmom keyword a similar scale factor is needed which is $10.0/3.0$ for spherical particles, but is anisotropic for aspherical particles (e.g. ellipsoids). Currently LAMMPS only applies an isotropic scale factor, and you can choose its magnitude as the specified value of the angmom keyword. If your aspherical particles are (nearly) spherical than a value of $40.0/3.0 = 3.3$ is a good choice. If they are highly aspherical, a value of 1.0 is as good a choice as any, since the effects on rotational diffusivity of the particles will be incorrect regardless. Note that for any reasonable scale factor, the thermostatting effect of the angmom keyword on the rotational temperature of the aspherical particles should still be valid.

The keyword scale allows the damp factor to be scaled up or down by the specified factor for atoms of that type. This can be useful when different atom types have different sizes or masses. It can be used multiple times to adjust damp for several atom types. Note that specifying a ratio of 2 increases the relaxation time which is equivalent to the solvent’s viscosity acting on particles with 1/2 the diameter. This is the opposite effect of scale factors used by the fix viscous command, since the damp factor in fix langevin is inversely related to the γ factor in fix viscous. Also note that the damping factor in fix langevin includes the particle mass in Ff, unlike fix viscous. Thus the mass and size of different atom types should be accounted for in the choice of ratio values.
The keyword `tally` enables the calculation of the cumulative energy added/subtracted to the atoms as they are thermostatted. Effectively it is the energy exchanged between the infinite thermal reservoir and the particles. As described below, this energy can then be printed out or added to the potential energy of the system to monitor energy conservation.

**Note:** This accumulated energy does NOT include kinetic energy removed by the `zero` flag. LAMMPS will print a warning when both options are active.

The keyword `zero` can be used to eliminate drift due to the thermostat. Because the random forces on different atoms are independent, they do not sum exactly to zero. As a result, this fix applies a small random force to the entire system, and the center-of-mass of the system undergoes a slow random walk. If the keyword `zero` is set to `yes`, the total random force is set exactly to zero by subtracting off an equal part of it from each atom in the group. As a result, the center-of-mass of a system with zero initial momentum will not drift over time.

The keyword `gjf` can be used to run the Gronbech-Jensen/Farago time-discretization of the Langevin model. As described in the papers cited below, the purpose of this method is to enable longer timesteps to be used (up to the numerical stability limit of the integrator), while still producing the correct Boltzmann distribution of atom positions.

The current implementation provides the user with the option to output the velocity in one of two forms: `vfull` or `vhalf`, which replaces the outdated option `yes`. The `gjf` option `vfull` outputs the on-site velocity given in *Gronbech-Jensen/Farago*; this velocity is shown to be systematically lower than the target temperature by a small amount, which grows quadratically with the timestep. The `gjf` option `vhalf` outputs the 2GJ half-step velocity given in *Gronbech Jensen/Gronbech-Jensen*; for linear systems, this velocity is shown to not have any statistical errors for any stable time step. An overview of statistically correct Boltzmann and Maxwell-Boltzmann sampling of true on-site and true half-step velocities is given in *Gronbech-Jensen*. Regardless of the choice of output velocity, the sampling of the configurational distribution of atom positions is the same, and linearly consistent with the target temperature.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 17.73.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior.

The `fix_modify temp` option is supported by this fix. You can use it to assign a temperature `compute` you have defined to this fix which will be used in its thermostating procedure, as described above. For consistency, the group used by this fix and by the compute should be the same.

The cumulative energy change in the system imposed by this fix is included in the thermodynamic output keywords `ecouple` and `econserve`, but only if the `tally` keyword to set to `yes`. See the thermo_style page for details.
This fix computes a global scalar which can be accessed by various output commands. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is "extensive". Note that calculation of this quantity also requires setting the tally keyword to yes.

This fix can ramp its target temperature over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

17.73.5 Restrictions

For gif do not choose damp=dt/2. gif is not compatible with run_style respa.

17.73.6 Related commands

```

Example input scripts available: examples/PACKAGES/drude

17.74.3 Description

Apply two Langevin thermostats as described in (Jiang1) for thermalizing the reduced degrees of freedom of Drude oscillators. This link describes how to use the thermalized Drude oscillator model in LAMMPS and polarizable models in LAMMPS are discussed on the Howto polarizable doc page.

Drude oscillators are a way to simulate polarizables atoms, by splitting them into a core and a Drude particle bound by a harmonic bond. The thermalization works by transforming the particles degrees of freedom by these equations. In these equations upper case denotes atomic or center of mass values and lower case denotes Drude particle or dipole values. Primes denote the transformed (reduced) values, while bare letters denote the original values.

Velocities:

\[
V' = \frac{MV + mv}{M'} \\
v' = v - V
\]

Masses:

\[
M' = M + m \\
m' = \frac{Mm}{M'}
\]

The Langevin forces are computed as

\[
F' = -\frac{M'}{damp_{com}} V' + F'_r \\
f' = -\frac{m'}{damp_{drude}} v' + f'_r
\]

\(F'_r\) is a random force proportional to \(\sqrt{\frac{2k_B T_{com} m'}{dt \, damp_{com}}}\), \(f'_r\) is a random force proportional to \(\sqrt{\frac{2k_B T_{drude} m'}{dt \, damp_{drude}}}\). Then the real forces acting on the particles are computed from the inverse transform:

\[
F = \frac{M}{M'} F' - f' \\
f = \frac{m}{M'} F' + f'
\]

This fix also thermostats non-polarizable atoms in the group at temperature \(T_{com}\), as if they had a massless Drude partner. The Drude particles themselves need not be in the group. The center of mass and the dipole are thermostatted iff the core atom is in the group.
Note that the thermostat effect of this fix is applied to only the translational degrees of freedom of the particles, which is an important consideration if finite-size particles, which have rotational degrees of freedom, are being thermostatted. The translational degrees of freedom can also have a bias velocity removed from them before thermostatting takes place; see the description below.

**Note:** Like the `fix langevin` command, this fix does NOT perform time integration. It only modifies forces to effect thermostatting. Thus you must use a separate time integration fix, like `fix nve` or `fix nph` to actually update the velocities and positions of atoms using the modified forces. Likewise, this fix should not normally be used on atoms that also have their temperature controlled by another fix - e.g. by `fix nvt` or `fix temp/rescale` commands.

See the [Howto thermostat](#) page for a discussion of different ways to compute temperature and perform thermostatting.

This fix requires each atom know whether it is a Drude particle or not. You must therefore use the `fix drude` command to specify the Drude status of each atom type.

**Note:** only the Drude core atoms need to be in the group specified for this fix. A Drude electron will be transformed together with its cores even if it is not itself in the group. It is safe to include Drude electrons or non-polarizable atoms in the group. The non-polarizable atoms will simply be thermostatted as if they had a massless Drude partner (electron).

**Note:** Ghost atoms need to know their velocity for this fix to act correctly. You must use the `comm_modify` command to enable this, e.g.

```
comm_modify vel yes
```

*Tcom* is the target temperature of the centers of mass, which would be used to thermostat the non-polarizable atoms. *Tdrude* is the (normally low) target temperature of the core-Drude particle pairs (dipoles). *Tcom* and *Tdrude* can be specified as an equal-style variable. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the target temperature.

Equal-style variables can specify formulas with various mathematical functions, and include `thermo_style` command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent temperature.

Like other fixes that perform thermostatting, this fix can be used with `compute commands` that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial region, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the `fix_modify` command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual `compute temp commands` to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

Note: The temperature thermostatting the core-Drude particle pairs should be chosen low enough, so as to mimic as closely as possible the self-consistent minimization. It must however be high enough, so that the dipoles can follow the local electric field exerted by the neighboring atoms. The optimal value probably depends on the temperature of the centers of mass and on the mass of the Drude particles.
\textit{damp\_com} is the characteristic time for reaching thermal equilibrium of the centers of mass. For example, a value of 100.0 means to relax the temperature of the centers of mass in a timespan of (roughly) 100 time units (tau or fs or ps - see the \texttt{units} command). \textit{damp\_drude} is the characteristic time for reaching thermal equilibrium of the dipoles. It is typically a few timesteps.

The number \textit{seed\_com} and \textit{seed\_drude} are positive integers. They set the seeds of the Marsaglia random number generators used for generating the random forces on centers of mass and on the dipoles. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.

The keyword \texttt{zero} can be used to eliminate drift due to the thermostat on centers of mass. Because the random forces on different centers of mass are independent, they do not sum exactly to zero. As a result, this fix applies a small random force to the entire system, and the momentum of the total center of mass of the system undergoes a slow random walk. If the keyword \texttt{zero} is set to \texttt{yes}, the total random force on the centers of mass is set exactly to zero by subtracting off an equal part of it from each center of mass in the group. As a result, the total center of mass of a system with zero initial momentum will not drift over time.

The actual temperatures of cores and Drude particles, in center-of-mass and relative coordinates, respectively, can be calculated using the \texttt{compute temp/drude} command.

Usage example for rigid bodies in the NPT ensemble:

```plaintext
comm_modify vel yes
fix TEMP all langevin/drude 300. 100. 1256 1. 20. 13977 zero yes
fix NPH ATOMS rigid/nph/small molecule iso 1. 1. 500.
fix NVE DRUDES nve
compute TDRUDE all temp/drude
```

Comments:

- Drude particles should not be in the rigid group, otherwise the Drude oscillators will be frozen and the system will lose its polarizability.
- \texttt{zero yes} avoids a drift of the center of mass of the system, but is a bit slower.
- Use two different random seeds to avoid unphysical correlations.
- Temperature is controlled by the fix \texttt{langevin/drude}, so the time-integration fixes do not thermostat. Don’t forget to time-integrate both cores and Drude particles.
- Pressure is time-integrated only once by using \texttt{nve} for Drude particles and \texttt{nph} for atoms/cores (or vice versa). Do not use \texttt{nph} for both.
- The temperatures of cores and Drude particles are calculated by \texttt{compute temp/drude}
- Contrary to the alternative thermostatting using Nose-Hoover thermostat fix \texttt{npt} and \texttt{fix drude/transform}, the \texttt{fix modify} command is not required here, because the fix \texttt{nph} computes the global pressure even if its group is \texttt{ATOMS}. This is what we want. If we thermostatted \texttt{ATOMS} using \texttt{npt}, the pressure should be the global one, but the temperature should be only that of the cores. That’s why the command \texttt{fix modify} should be called in that case.
17.74.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior.

The fix_modify temp option is supported by this fix. You can use it to assign a temperature compute you have defined to this fix which will be used in its thermostating procedure, as described above. For consistency, the group used by the compute should include the group of this fix and the Drude particles.

This fix is not invoked during energy minimization.

17.74.5 Restrictions

none

17.74.6 Related commands

fix langevin, fix drude, fix drude/transform, compute temp/drude, pair_style thole

17.74.7 Default

The option defaults are zero = no.

17.75 fix langevin/eff command

17.75.1 Syntax

```
fix ID group-ID langevin/eff Tstart Tstop damp seed keyword values ...  
```

- ID, group-ID are documented in fix command
- langevin/eff = style name of this fix command
- Tstart,Tstop = desired temperature at start/end of run (temperature units)
- damp = damping parameter (time units)
- seed = random number seed to use for white noise (positive integer)
- zero or more keyword/value pairs may be appended

keyword = scale or tally or zero

- scale values = type ratio
  - type = atom type (1-N)
  - ratio = factor by which to scale the damping coefficient
- tally values = no or yes
  - no = do not tally the energy added/subtracted to atoms
  - yes = do tally the energy added/subtracted to atoms
zero value = no or yes
no = do not set total random force to zero
yes = set total random force to zero

17.75.2 Examples

```plaintext
fix 3 boundary langevin/eff 1.0 1.0 10.0 699483
fix 1 all langevin/eff 1.0 1.1 10.0 48279 scale 3 1.5
```

17.75.3 Description

Apply a Langevin thermostat as described in (Schneider) to a group of nuclei and electrons in the electron force field model. Used with the `fix nve/eff`, this command performs Brownian dynamics (BD), since the total force on each atom will have the form:

\[ F = F_c + F_f + F_r \]
\[ F_f = -\frac{m}{\text{damp}} v \]
\[ F_r \propto \sqrt{\frac{k_B T m}{\text{damp}}} \frac{dt}{\text{damp}} \]

\( F_c \) is the conservative force computed via the usual inter-particle interactions (pair_style). The \( F_f \) and \( F_r \) terms are added by this fix on a per-particle basis.

The operation of this fix is exactly like that described by the `fix langevin` command, except that the thermostatting is also applied to the radial electron velocity for electron particles.

17.75.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior.

The `fix_modify temp` option is supported by this fix. You can use it to assign a temperature `compute` you have defined to this fix which will be used in its thermostatting procedure, as described above. For consistency, the group used by this fix and by the compute should be the same.

The cumulative energy change in the system imposed by this fix is included in the thermodynamic output keywords `ecouple` and `econserve`, but only if the `tally` keyword to set to `yes`. See the `thermo_style` page for details.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”. Note that calculation of this quantity also requires setting the `tally` keyword to `yes`.

This fix can ramp its target temperature over multiple runs, using the `start` and `stop` keywords of the `run` command. See the `run` command for details of how to do this.

This fix is not invoked during energy minimization.
17.75.5 Restrictions

none

This fix is part of the EFF package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

17.75.6 Related commands

*fix langevin*

17.75.7 Default

The option defaults are scale = 1.0 for all types and tally = no.

(Schneider) Schneider and Stoll, Phys Rev B, 17, 1302 (1978).

17.76 fix langevin/spin command

17.76.1 Syntax

```latex
fix ID group-ID langevin/spin T Tdamp seed
```

- ID, group-ID are documented in *fix* command
- langevin/spin = style name of this fix command
- T = desired temperature of the bath (temperature units, K in metal units)
- Tdamp = transverse magnetic damping parameter (adim)
- seed = random number seed to use for white noise (positive integer)

17.76.2 Examples

```latex
fix 2 all langevin/spin 300.0 0.01 21
```

17.76.3 Description

Apply a Langevin thermostat as described in (Mayergoyz) to the magnetic spins associated to the atoms. Used with *fix nve/spin*, this command performs Brownian dynamics (BD). A random torque and a transverse dissipation are applied to each spin *i* according to the following stochastic differential equation:

\[
\frac{d\vec{s}_i}{dt} = \frac{1}{(1 + \lambda^2)} \left((\vec{\omega}_i + \vec{\eta}) \times \vec{s}_i + \lambda \vec{s}_i \times (\vec{\omega}_i \times \vec{s}_i)\right)
\]

with \(\lambda\) the transverse damping, and \(\eta\) a random vector. This equation is referred to as the stochastic Landau-Lifshitz-Gilbert (sLLG) equation.
The components of \( \eta \) are drawn from a Gaussian probability law. Their amplitude is defined as a proportion of the temperature of the external thermostat \( T \) (in K in metal units).

More details about this implementation are reported in \( \text{(Tranchida)} \).

Note: due to the form of the sLLG equation, this fix has to be defined just before the nve/spin fix (and after all other magnetic fixes). As an example:

```
fix 1 all precession/spin zeeman 0.01 0.0 0.0 1.0
fix 2 all langevin/spin 300.0 0.01 21
fix 3 all nve/spin lattice moving
```

is correct, but defining a force/spin command after the langevin/spin command would give an error message.

Note: The random \# seed must be a positive integer. A Marsaglia random number generator is used. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.

---

### 17.76.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior.

This fix is not invoked during energy minimization.

---

### 17.76.5 Restrictions

The langevin/spin fix is part of the SPIN package. This style is only enabled if LAMMPS was built with this package. See the Build package page for more info.

The numerical integration has to be performed with fix nve/spin when fix langevin/spin is enabled.

This fix has to be the last defined magnetic fix before the time integration fix (e.g. fix nve/spin).

---

### 17.76.6 Related commands

fix nve/spin, fix precession/spin

17.77 fix latte command

17.77.1 Syntax

```latex
fix ID group-ID latte peID
```

- ID, group-ID are documented in `fix` command
- latte = style name of this fix command
- peID = NULL or ID of compute used to calculate per-atom energy

17.77.2 Examples

```latex
fix dftb all latte NULL
```

17.77.3 Description

This fix style is a wrapper on the self-consistent charge transfer density functional based tight binding (DFTB) code LATTE. If you download and build LATTE, it can be called as a library by LAMMPS via this fix to run dynamics or perform energy minimization using DFTB forces and energies computed by LATTE.

LATTE is principally developed and supported by Marc Cawkwell and co-workers at Los Alamos National Laboratory (LANL). See the full list of contributors in the src/LATTE/README file.

To use this fix, the LATTE program needs to be compiled as a library and linked with LAMMPS. LATTE can be downloaded (or cloned) from https://github.com/lanl/LATTE. Instructions on how to download and build LATTE on your system can be found in the lib/latte/README. Note that you can also use the “make lib-latte” command from the LAMMPS src directory to automate this process.

Once LAMMPS is built with the LATTE package, you can run the example input scripts for molecular dynamics or energy minimization that are found in examples/latte.

A step-by-step tutorial can be followed at: LAMMPS-LATTE tutorial

The `peID` argument is not yet supported by fix latte, so it must be specified as NULL. Eventually it will be used to enable LAMMPS to calculate a Coulomb potential as an alternative to LATTE performing the calculation.

LATTE is a code for performing self-consistent charge transfer tight-binding (SC-TB) calculations of total energies and the forces acting on atoms in molecules and solids. This tight-binding method is becoming more and more popular and widely used in chemistry, biochemistry, material science, etc.

The SC-TB formalism is derived from an expansion of the Kohn-Sham density functional to second order in charge fluctuations about a reference charge of overlapping atom-centered densities and bond integrals are parameterized using a Slater-Koster tight-binding approach. This procedure, which usually is referred to as the DFTB method has been described in detail by (Elstner) and (Finnis) and coworkers.

The work of the LATTE developers follows that of Elstner closely with respect to the physical model. However, the development of LATTE is geared principally toward large-scale, long duration, microcanonical quantum-based Born-Oppenheimer molecular dynamics (QMD) simulations. One of the main bottlenecks of an electronic structure calculation is the solution of the generalized eigenvalue problem which scales with the cube of the system size $O(N^3)$.

The Theoretical and Computer sciences divisions at Los Alamos National Laboratory have accumulated large experience addressing this issue by calculating the density matrix directly instead of using diagonalization. We typically use
a recursive sparse Fermi-operator expansion using second-order spectral projection functions (SP2-algorithm), which was introduced by Niklasson in 2002 ([Niklasson2002](#)), ([Rubensson](#)), ([Mniszewski](#)). When the matrices involved in the recursive expansion are sufficiently sparse, the calculation of the density matrix scales linearly as a function of the system size $O(N)$.

Another important feature is the extended Lagrangian framework for Born-Oppenheimer molecular dynamics (XL-BOMD) ([Niklasson2008](#)) ([Niklasson2014](#)) ([Niklasson2017](#)) that allows for a drastic reduction or even a complete removal of the iterative self-consistent field optimization. Often only a single density matrix calculation per molecular dynamics time step is required, yet total energy stability is well maintained. The SP2 and XL-BOMD techniques enables stable linear scaling MD simulations with a very small computational overhead. This opens a number of opportunities in many different areas of chemistry and materials science, as we now can simulate larger system sizes and longer time scales ([Cawkwell2012](#)), ([Negre2016](#)).

### 17.77.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The `fix_modify energy` option is supported by this fix to add the potential energy computed by LATTE to the global potential energy of the system as part of thermodynamic output. The default setting for this fix is `fix_modify energy yes`.

The `fix_modify virial` option is supported by this fix to add the contribution compute by LATTE to the global pressure of the system via the `compute pressure` command. This can be accessed by thermodynamic output. The default setting for this fix is `fix_modify virial yes`.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the potential energy discussed above. The scalar value calculated by this fix is “extensive”.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command.

The DFTB forces computed by LATTE via this fix are imposed during an energy minimization, invoked by the `minimize` command.

**Note:** If you want the potential energy associated with the DFTB forces to be included in the total potential energy of the system (the quantity being minimized), you MUST not disable the `fix_modify energy` option for this fix.

### 17.77.5 Restrictions

This fix is part of the LATTE package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

You must use metal units, as set by the `units` command to use this fix.

LATTE does not currently compute per-atom energy or per-atom virial contributions. So they will not show up as part of the calculations performed by the `compute pe/atom` or `compute stress/atom` commands.

Currently, LAMMPS must be run in serial or as a single MPI task, to use this fix. This is typically not a bottleneck, since LATTE will be doing 99% or more of the work to compute quantum-accurate forces.
Note: NEB calculations can be done using this fix using multiple replicas and running LAMMPS in parallel. However, each replica must be run on a single MPI task. For details, see the neb command page and the -partition command-line switch.

17.78 fix lb/fluid command

17.78.1 Syntax

```
fix ID group-ID lb/fluid nevery viscosity density keyword values ...
```

- **ID, group-ID** are documented in fix command
- **lb/fluid =** style name of this fix command
- **nevery =** update the lattice-Boltzmann fluid every this many timesteps (should normally be 1)
- **viscosity =** the fluid viscosity (units of mass/(time*length)).
- **density =** the fluid density.
• zero or more keyword/value pairs may be appended

• keyword = dx or dm or noise or stencil or read_restart or write_restart or zwall_velocity or pressurebcx or bodyforce or D3Q19 or dumpxdmf or dof or scaleGamma or a0 or npits or wp or sw

dx values = dx_LB = the lattice spacing.
dm values = dm_LB = the lattice-Boltzmann mass unit.
noise values = Temperature seed
  Temperature = fluid temperature.
  seed = random number generator seed (positive integer)
stencil values = 2 (trilinear stencil, the default), 3 (3-point immersed boundary stencil), or 4 (4-point Keys' interpolation stencil)
read_restart values = restart file = name of the restart file to use to restart a fluid run.
write_restart values = N = write a restart file every N MD timesteps.
zwall_velocity values = velocity_bottom velocity_top = velocities along the y-direction of the bottom and top walls (located at z=zmin and z=zmax).
pressurebcx values = pgradav = imposes a pressure jump at the (periodic) x-boundary of pgradav*Lx*1000.
bodyforce values = bodyforcex bodyforcey bodyforcez = the x, y and z components of a constant body force added to the fluid.
D3Q19 values = none (used to switch from the default D3Q15, 15 velocity lattice, to the D3Q19, 19 velocity lattice).
dumpxdmf values = N file timeI
  N = output the force and torque every N timesteps
  file = output file name
  timeI = 1 (use simulation time to index xdmf file), 0 (use output frame number to index xdmf file)
dof values = dof = specify the number of degrees of freedom for temperature calculation
scaleGamma values = type gammaFactor
  type = atom type (1-N)
  gammaFactor = factor to scale the setGamma gamma value by, for the specified atom type.
a0 values = a_0_real = the square of the speed of sound in the fluid.
npits values = npits h_p l_p l_pp l_e
  npits = number of pit regions
  h_p = z-height of pit regions (floor to bottom of slit)
  l_p = x-length of pit regions
  l_pp = x-length of slit regions between consecutive pits
  l_e = x-length of slit regions at ends
wp values = w_p = y-width of slit regions (defaults to full width if not present or if sw active)
sw values = none (turns on y-sidewalls (in xz plane) if npits option active)

```

17.78.3 Description

Changed in version 24Mar2022.

Implement a lattice-Boltzmann fluid on a uniform mesh covering the LAMMPS simulation domain. Note that this fix was updated in 2022 and is not backward compatible with the previous version. If you need the previous version, please download an older version of LAMMPS. The MD particles described by group-ID apply a velocity dependent force to the fluid.

The lattice-Boltzmann algorithm solves for the fluid motion governed by the Navier Stokes equations,

\[
\begin{align*}
\frac{\partial}{\partial t} \rho + \partial_\beta (\rho u_\beta) &= 0 \\
\frac{\partial}{\partial t} (\rho u_\alpha) + \partial_\beta (\rho u_\alpha u_\beta) &= \partial_\beta \sigma_{\alpha\beta} + F_\alpha + \partial_\beta (\eta_{\alpha\beta\gamma\nu} \partial_\gamma u_\nu)
\end{align*}
\]

with,

\[
\eta_{\alpha\beta\gamma\nu} = \eta \left[ \delta_{\alpha\gamma} \delta_{\beta\nu} + \delta_{\alpha\nu} \delta_{\beta\gamma} - \frac{2}{3} \delta_{\alpha\beta} \delta_{\gamma\nu} \right] + \Lambda \delta_{\alpha\beta} \delta_{\gamma\nu}
\]

where \(\rho\) is the fluid density, \(u\) is the local fluid velocity, \(\sigma\) is the stress tensor, \(F\) is a local external force, and \(\eta\) and \(\Lambda\) are the shear and bulk viscosities respectively. Here, we have implemented

\[
\sigma_{\alpha\beta} = -P_{\alpha\beta} = -\rho a_0 \delta_{\alpha\beta}
\]

with \(a_0\) set to \(\frac{1}{3} \frac{dx}{dt}^2\) by default. You should not normally need to change this default.

The algorithm involves tracking the time evolution of a set of partial distribution functions which evolve according to a velocity discretized version of the Boltzmann equation,

\[
\left( \frac{\partial}{\partial t} + e_{i\alpha} \partial_\alpha \right) f_i = -\frac{1}{\tau} (f_i - f_i^{eq}) + W_i
\]

where the first term on the right hand side represents a single time relaxation towards the equilibrium distribution function, and \(\tau\) is a parameter physically related to the viscosity. On a technical note, we have implemented a 15 velocity model (D3Q15) as default; however, the user can switch to a 19 velocity model (D3Q19) through the use of the D3Q19 keyword. Physical variables are then defined in terms of moments of the distribution functions,

\[
\rho = \sum_i f_i \\
\rho u_\alpha = \sum_i f_i e_{i\alpha}
\]

Full details of the lattice-Boltzmann algorithm used can be found in Denniston et al..

The fluid is coupled to the MD particles described by group-ID through a velocity dependent force. The contribution to the fluid force on a given lattice mesh site \(j\) due to MD particle \(\alpha\) is calculated as:

\[
F_{ja} = \gamma (v_n - u_f) \zeta_{ja}
\]
where \( v_n \) is the velocity of the MD particle, \( u_f \) is the fluid velocity interpolated to the particle location, and \( \gamma \) is the force coupling constant. This force, as with most forces in LAMMPS, and hence the velocities, are calculated at the half-time step. \( \zeta \) is a weight assigned to the grid point, obtained by distributing the particle to the nearest lattice sites.

The force coupling constant, \( \gamma \), is calculated according to

\[
\gamma = \frac{2m_im_v}{m_i + m_v} \left( \frac{1}{\Delta t} \right)
\]

Here, \( m_i \) is the mass of the MD particle, \( m_v \) is a representative fluid mass at the particle location, and \( \Delta t \) is the time step. The fluid mass \( m_v \) that the MD particle interacts with is calculated internally. This coupling is chosen to constrain the particle and associated fluid velocity to match at the end of the time step. As with other constraints, such as shake, this constraint can remove degrees of freedom from the simulation which are accounted for internally in the algorithm.

**Note:** While this fix applies the force of the particles on the fluid, it does not apply the force of the fluid to the particles. There is only one option to include this hydrodynamic force on the particles, and that is through the use of the `lb/viscous` fix. This fix adds the hydrodynamic force to the total force acting on the particles, after which any of the built-in LAMMPS integrators can be used to integrate the particle motion. If the `lb/viscous` fix is NOT used to add the hydrodynamic force to the total force acting on the particles, this physically corresponds to a situation in which an infinitely massive particle is moving through the fluid (since collisions between the particle and the fluid do not act to change the particle’s velocity). In this case, setting `scaleGamma` to -1 for the corresponding particle type will explicitly take this limit (of infinite particle mass) in computing the force coupling for the fluid force.

Physical parameters describing the fluid are specified through `viscosity` and `density`. These parameters should all be given in terms of the mass, distance, and time units chosen for the main LAMMPS run, as they are scaled by the LB timestep, lattice spacing, and mass unit, inside the fix.

The `dx` keyword allows the user to specify a value for the LB grid spacing and the `dm` keyword allows the user to specify the LB mass unit. Inside the fix, parameters are scaled by the lattice-Boltzmann timestep, \( dt_{LB} \), grid spacing, \( dx_{LB} \), and mass unit, \( dm_{LB} \). \( dt_{LB} \) is set equal to \( nevery \cdot dt_{MD} \), where \( dt_{MD} \) is the MD timestep. By default, \( dm_{LB} \) is set equal to 1.0, and \( dx_{LB} \) is chosen so that \( \frac{1}{\tau} \cdot \frac{dt}{\rho dx^2} \) is approximately equal to 1.

**Note:** Care must be taken when choosing both a value for \( dx_{LB} \), and a simulation domain size. This fix uses the same subdivision of the simulation domain among processors as the main LAMMPS program. In order to uniformly cover the simulation domain with lattice sites, the lengths of the individual LAMMPS sub-domains must all be evenly divisible by \( dx_{LB} \). If the simulation domain size is cubic, with equal lengths in all dimensions, and the default value for \( dx_{LB} \) is used, this will automatically be satisfied.

If the `noise` keyword is used, followed by a positive temperature value, and a positive integer random number seed, the thermal LB algorithm of Adhikari et al. is used.

If the keyword `stencil` is used, the value sets the number of interpolation points used in each direction. For this, the user has the choice between a trilinear stencil (stencil 2), which provides a support of 8 lattice sites, or the 3-point immersed boundary method stencil (stencil 3), which provides a support of 27 lattice sites, or the 4-point Keys’ interpolation stencil (stencil 4), which provides a support of 64 lattice sites. The trilinear stencil is the default as it is better suited for simulation of objects close to walls or other objects, due to its smaller support. The 3-point stencil provides smoother motion of the lattice and is suitable for particles not likely to be close to walls or other objects.

If the keyword `write_restart` is used, followed by a positive integer, \( N \), a binary restart file is printed every \( N \) LB timesteps. This restart file only contains information about the fluid. Therefore, a LAMMPS restart file should also be written in order to print out full details of the simulation.

**Note:** When a large number of lattice grid points are used, the restart files may become quite large.
In order to restart the fluid portion of the simulation, the keyword `read_restart` is specified, followed by the name of the binary `lb_fluid` restart file to be used.

If the `zwall_velocity` keyword is used y-velocities are assigned to the lower and upper walls. This keyword requires the presence of walls in the z-direction. This is set by assigning fixed boundary conditions in the z-direction. If fixed boundary conditions are present in the z-direction, and this keyword is not used, the walls are assumed to be stationary.

If the `pressurebcx` keyword is used, a pressure jump (implemented by a step jump in density) is imposed at the (periodic) x-boundary. The value set specifies what would be the resulting equilibrium average pressure gradient in the x-direction if the system had a constant cross-section (i.e. resistance to flow). It is converted to a pressure jump by multiplication by the system size in the x-direction. As this value should normally be quite small, it is also assumed to be scaled by 1000.

If the `bodyforce` keyword is used, a constant body force is added to the fluid, defined by its x, y and z components.

If the keyword `D3Q19` is used, the 19 velocity (D3Q19) lattice is used by the lattice-Boltzmann algorithm. By default, the 15 velocity (D3Q15) lattice is used.

If the `dumpxdmf` keyword is used, followed by a positive integer, N, and a filename, the fluid densities and velocities at each lattice site are output to an xdmf file every N timesteps. This is a binary file format that can be read by visualization packages such as Paraview. The xdmf file format contains a time index for each frame dump and the value time = 1 uses simulation time while 0 uses the output frame number to index xdmf file. The later can be useful if the `dump vtk` command is used to output the particle positions at the same timesteps and you want to visualize both the fluid and particle data together in Paraview.

The `scaleGamma` keyword allows the user to scale the $\gamma$ value by a factor, gammaFactor, for a given atom type. Setting `scaleGamma` to -1 for the corresponding particle type will explicitly take the limit of infinite particle mass in computing the force coupling for the fluid force (see note above).

If the `a0` keyword is used, the value specified is used for the square of the speed of sound in the fluid. If this keyword is not present, the speed of sound squared is set equal to $\frac{1}{3} \left( \frac{dx_{LB}}{dt_{LB}} \right)^2$. Setting $a0 > \left( \frac{dx_{LB}}{dt_{LB}} \right)^2$ is not allowed, as this may lead to instabilities. As the speed of sound should usually be much larger than any fluid velocity of interest, its value does not normally have a significant impact on the results. As such, it is usually best to use the default for this option.

The `npits` keyword (followed by integer arguments: npits, h_p, l_p, l_pp, l_e) sets the fluid domain to the pits geometry. These arguments should only be used if you actually want something more complex than a rectangular/cubic geometry. The npits value sets the number of pits regions (arranged along x). The remaining arguments are sizes measured in multiples of dx_lb: h_p is the z-height of the pit regions, l_p is the x-length of the pit regions, l_pp is the length of the region between consecutive pits (referred to as a “slit” region), and l_e is the x-length of the slit regions at each end of the channel. The pit geometry must fill the system in the x-direction but can be longer, in which case it is truncated (which enables asymmetric entrance/exit end sections). The additional wp keyword allows the width (in y-direction) of the pit to be specified (the default is full width) and the sw keyword indicates that there should be sidewalls in the y-direction (default is periodic in y-direction). These parameters are illustrated below:

### Sideview (in xz plane) of pit geometry:

```

For further details, as well as descriptions and results of several test runs, see Denniston et al.. Please include a citation to this paper if the lb_fluid fix is used in work contributing to published research.

### 17.78.4 Restart, fix_modify, output, run start/stop, minimize info

Due to the large size of the fluid data, this fix writes it’s own binary restart files, if requested, independent of the main LAMMPS binary restart files; no information about lb_fluid is written to the main LAMMPS binary restart files.

None of the fix_modify options are relevant to this fix.

The fix computes a global scalar which can be accessed by various output commands. The scalar is the current temperature of the group of particles described by group-ID along with the fluid constrained to move with them. The temperature is computed via the kinetic energy of the group and fluid constrained to move with them and the total number of degrees of freedom (calculated internally). If the particles are not integrated independently (such as via fix NVE) but have additional constraints imposed on them (such as via integration using fix rigid) the degrees of freedom removed from these additional constraints will not be properly accounted for. In this case, the user can specify the total degrees of freedom independently using the dof keyword.

The fix also computes a global array of values which can be accessed by various output commands. There are 5 entries in the array. The first entry is the temperature of the fluid, the second entry is the total mass of the fluid plus particles, the third through fifth entries give the x, y, and z total momentum of the fluid plus particles.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

### 17.78.5 Restrictions

This fix is part of the LATBOLTZ package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This fix can only be used with an orthogonal simulation domain.

The boundary conditions for the fluid are specified independently to the particles. However, these should normally be specified consistently via the main LAMMPS boundary command (p p p, p p f, and p f f are the only consistent possibilities). Shrink-wrapped boundary conditions are not permitted with this fix.

This fix must be used before any of fix lb/viscous and fix lb/momentum as the fluid needs to be initialized before any of these routines try to access its properties. In addition, in order for the hydrodynamic forces to be added to the particles, this fix must be used in conjunction with the lb/viscous fix.
This fix needs to be used in conjunction with a standard LAMMPS integrator such as `fix NVE` or `fix rigid`.

### 17.78.6 Related commands

`fix lb/viscous`, `fix lb/momentum`

### 17.78.7 Default

\[ dx \text{ is chosen such that } \frac{\tau}{\frac{3\rho dt_{LB}}{\rho dx_{LB}}} = 1. \]
\[ dm \text{ is set equal to } 1.0. \]
\[ a0 \text{ is set equal to } \frac{1}{3} \left( \frac{dx_{LB}}{dt_{LB}} \right)^2. \]

The trilinear stencil is used as the default interpolation method. The D3Q15 lattice is used for the lattice-Boltzmann algorithm.

### 17.79 fix lb/momentum command

#### 17.79.1 Syntax

```
fine ID group-ID lb/momentum nevery keyword values ...
```

- ID, group-ID are documented in the `fix` command
- `lb/momentum` = style name of this fix command
- `nevery` = adjust the momentum every this many timesteps
- zero or more keyword/value pairs may be appended
- `keyword = linear`
  - `linear values = xflag yflag zflag`
  - `xflag,yflag,zflag = 0/1` to exclude/include each dimension.

#### 17.79.2 Examples

```
fine 1 sphere lb/momentum
fine 1 all lb/momentum linear 1 1 0
```
17.79.3 Description

This fix is based on the `fix momentum` command, and was created to be used in place of that command, when a lattice-Boltzmann fluid is present.

Zero the total linear momentum of the system, including both the atoms specified by group-ID and the lattice-Boltzmann fluid every `every` timesteps. If there are no atoms specified by group-ID only the fluid momentum is affected. This is accomplished by adjusting the particle velocities and the fluid velocities at each lattice site.

**Note:** This fix only considers the linear momentum of the system.

By default, the subtraction is performed for each dimension. This can be changed by specifying the keyword `linear`, along with a set of three flags set to 0/1 in order to exclude/include the corresponding dimension.

17.79.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.79.5 Restrictions

Can only be used if a lattice-Boltzmann fluid has been created via the `fix lb/fluid` command, and must come after this command.

This fix is part of the LATBOLTZ package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

17.79.6 Related commands

`fix momentum, fix lb/fluid`

17.79.7 Default

Zeros the total system linear momentum in each dimension.

17.80 fix lb/viscous command

17.80.1 Syntax

```
fix ID group-ID lb/viscous
```

- ID, group-ID are documented in `fix` command
- `lb/viscous` = style name of this fix command
17.80.2 Examples

`fix 1 flow lb/viscous`

17.80.3 Description

This fix is similar to the `fix viscous` command, and is to be used in place of that command when a lattice-Boltzmann fluid is present using the `fix lb/fluid`. This should be used in conjunction with one of the built-in LAMMPS integrators, such as `fix NVE` or `fix rigid`.

This fix adds a viscous force to each atom to cause it move with the same velocity as the fluid (an equal and opposite force is applied to the fluid via `fix lb/fluid`). When `fix lb/fluid` is called with the noise option, the atoms will also experience random forces which will thermalize them to the same temperature as the fluid. In this way, the combination of this fix with `fix lb/fluid` and a LAMMPS integrator like `fix NVE` is analogous to `fix langevin` except here the fluid is explicit. The temperature of the particles can be monitored via the scalar output of `fix lb/fluid`.

For details of this fix, as well as descriptions and results of several test runs, see Denniston et al.. Please include a citation to this paper if this fix is used in work contributing to published research.

17.80.4 Restart, fix_modify, output, run start/stop, minimize info

As described in the `fix viscous` documentation:

“No information about this fix is written to binary restart files. None of the `fix_modify` options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the `start/stop` keywords of the `run` command.

The forces due to this fix are imposed during an energy minimization, invoked by the `minimize` command. This fix should only be used with damped dynamics minimizers that allow for non-conservative forces. See the `min_style` command for details.”

17.80.5 Restrictions

This fix is part of the LATBOLTZ package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

Can only be used if a lattice-Boltzmann fluid has been created via the `fix lb/fluid` command, and must come after this command.

17.80.6 Related commands

17.81 fix lineforce command

17.81.1 Syntax

fix ID group-ID lineforce x y z

- ID, group-ID are documented in fix command
- lineforce = style name of this fix command
- x y z = direction of line as a 3-vector

17.81.2 Examples

fix hold boundary lineforce 0.0 1.0 1.0

17.81.3 Description

Adjust the forces on each atom in the group so that only the component of force along the linear direction specified by the vector (x,y,z) remains. This is done by subtracting out components of force in the plane perpendicular to the line. If the initial velocity of the atom is 0.0 (or along the line), then it should continue to move along the line thereafter.

17.81.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command.

17.81.5 Restrictions

17.82 fix manifoldforce command

17.82.1 Syntax

```plaintext
fix ID group-ID manifoldforce manifold manifold-args ...
```

- ID, group-ID are documented in *fix* command
- manifold = name of the manifold
- manifold-args = parameters for the manifold

17.82.2 Examples

```plaintext
fix constrain all manifoldforce sphere 5.0
```

17.82.3 Description

This fix subtracts each time step from the force the component along the normal of the specified *manifold*. This can be used in combination with *minimize* to remove overlap between particles while keeping them (roughly) constrained to the given manifold, e.g. to set up a run with *fix nve/manifold/rattle*. I have found that only *hftn* and *quickmin* with a very small time step perform adequately though.

17.82.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is invoked during *energy minimization*.
17.82.5 Restrictions
This fix is part of the MANIFOLD package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

Only use this with min_style hftn or min_style quickmin. If not, the constraints will not be satisfied very well at all. A warning is generated if the min_style is incompatible but no error.

17.82.6 Related commands
fix nve/manifold/rattle, fix nvt/manifold/rattle

17.83 fix mdi/aimd command

17.83.1 Syntax

fix ID group-ID mdi/aimd keyword

• ID, group-ID are documented in fix command
• mdi/aimd = style name of this fix command

17.83.2 Examples

fix 1 all mdi/aimd

17.83.3 Description
This command enables LAMMPS to act as a client with another server code to couple the two codes together to perform ab initio MD (AIMD) simulations.

More specifically, this command causes LAMMPS to begin using the MDI Library to run as an MDI driver (client), which sends MDI commands to an external MDI engine code (server) which in the case of AIMD is a quantum mechanics (QM) code, or could be LAMMPS itself, acting as a surrogate for a QM code. See the Howto mdi page for more information about how LAMMPS can operate as either an MDI driver or engine.

The examples/mdi directory contains input scripts performing AIMD in this manner with LAMMPS acting as both a driver and an engine (surrogate for a QM code). The examples/mdi/README file explains how to launch both driver and engine codes so that they communicate using the MDI library via either MPI or sockets. Any QM code that supports MDI could be used in place of LAMMPS acting as a QM surrogate. See the Howto mdi page for a current list (March 2022) of such QM codes.

The engine code can run either as a stand-alone code, launched at the same time as LAMMPS, or as a plugin library. See the mdi plugin command for how to trigger LAMMPS to load the plugin library. Again, the examples/mdi/README file explains how to launch both driver and engine codes so that engine is used in plugin mode.
This fix performs the timestepping portion of an AIMD simulation. Both LAMMPS and the engine code (QM or LAMMPS) should define the same system (simulation box, atoms and their types) in their respective input scripts. LAMMPS then begins its timestepping.

At the point in each timestep when LAMMPS needs the force on each atom, it communicates with the engine code. It sends the current simulation box size and shape (if they change dynamically, e.g. during an NPT simulation), and the current atom coordinates. The engine code computes quantum forces on each atom and returns them to LAMMPS. If LAMMPS also needs the system energy and/or virial, it requests those values from the engine code as well.

### 17.83.4 Restrictions

This command is part of the MDI package. It is only enabled if LAMMPS was built with that package. See the [Build package page](#) for more info.

To use LAMMPS as an MDI driver in conjunction with other MDI-enabled atomistic codes, the `units` command should be used to specify *real* or *metal* units. This will ensure the correct unit conversions between LAMMPS and MDI units, which the other codes will also perform in their preferred units.

LAMMPS can also be used as an MDI driver in other unit choices it supports, e.g. *lj*, but then no unit conversion is performed.

```

17.84.3 Description

Perform updates of position, velocity, internal energy and local density for mesoscopic particles in the group each
timestep using the specified settings or formulas, without regard to forces on the particles. This can be useful for
boundary, solid bodies or other particles, whose movement can influence nearby particles.

The operation of this fix is exactly like that described by the fix move command, except that particles’ density, internal
energy and extrapolated velocity are also updated.

Note: The particles affected by this fix should not be time integrated by other fixes (e.g. fix sph, fix sph/stationary),
since that will change their positions and velocities twice.

Note: As particles move due to this fix, they will pass through periodic boundaries and be remapped to the other side
of the simulation box, just as they would during normal time integration (e.g. via the fix sph command). It is up to you
to decide whether periodic boundaries are appropriate with the kind of particle motion you are prescribing with this
fix.

Note: As discussed below, particles are moved relative to their initial position at the time the fix is specified. These
initial coordinates are stored by the fix in “unwrapped” form, by using the image flags associated with each particle.
See the dump custom command for a discussion of “unwrapped” coordinates. See the Atoms section of the read_data
command for a discussion of image flags and how they are set for each particle. You can reset the image flags (e.g. to
0) before invoking this fix by using the set image command.

The linear style moves particles at a constant velocity, so that their position $X = (x,y,z)$ as a function of time is given
in vector notation as

$$X(t) = X_0 + V \cdot \delta$$

where $X_0 = (x_0,y_0,z_0)$ is their position at the time the fix is specified, $V$ is the specified velocity vector with components
$(V_x,V_y,V_z)$, and $\delta$ is the time elapsed since the fix was specified. This style also sets the velocity of each particle to $V$
$= (V_x,V_y,V_z)$. If any of the velocity components is specified as NULL, then the position and velocity of that component
is time integrated the same as the \texttt{fix sph} command would perform, using the corresponding force component on the particle.

Note that the \textit{linear} style is identical to using the \textit{variable} style with an \textit{equal-style variable} that uses the \texttt{vdisplace()} function. E.g.

\begin{verbatim}
variable V equal 10.0
variable x equal vdisplace(0.0,$V)
fix 1 boundary move variable v_x NULL NULL v_V NULL NULL
\end{verbatim}

The \textit{wiggle} style moves particles in an oscillatory fashion, so that their position $X = (x,y,z)$ as a function of time is given in vector notation as

$$X(t) = X_0 + A \sin(\omega\delta)$$

where $X_0 = (x_0,y_0,z_0)$ is their position at the time the fix is specified, $A$ is the specified amplitude vector with components $(Ax,Ay,Az)$, $\omega$ is $2 \pi / \text{period}$, and $\delta$ is the time elapsed since the fix was specified. This style also sets the velocity of each particle to the time derivative of this expression. If any of the amplitude components is specified as NULL, then the position and velocity of that component is time integrated the same as the \texttt{fix sph} command would perform, using the corresponding force component on the particle.

Note that the \textit{wiggle} style is identical to using the \textit{variable} style with \textit{equal-style variables} that use the \texttt{swiggle()} and \texttt{cwiggle()} functions. E.g.

\begin{verbatim}
variable A equal 10.0
variable T equal 5.0
variable omega equal 2.0*PI/$T$
variable x equal swiggle(0.0,$A,$T)
variable v equal v_omega*($A-cwiggle(0.0,$A,$T))
fix 1 boundary move variable v_x NULL NULL v_v NULL NULL
\end{verbatim}

The \textit{rotate} style rotates particles around a rotation axis $R = (Rx,Ry,Rz)$ that goes through a point $P = (Px,Py,Pz)$. The \textit{period} of the rotation is also specified. The direction of rotation for the particles around the rotation axis is consistent with the right-hand rule: if your right-hand thumb points along $R$, then your fingers wrap around the axis in the direction of rotation.

This style also sets the velocity of each particle to $(\omega \times R_{\perp})$ where $\omega$ is its angular velocity around the rotation axis and $R_{\perp}$ is a perpendicular vector from the rotation axis to the particle.

The \textit{variable} style allows the position and velocity components of each particle to be set by formulas specified via the \texttt{variable} command. Each of the 6 variables is specified as an argument to the fix as \texttt{v\_name}, where name is the variable name that is defined elsewhere in the input script.

Each variable must be of either the \textit{equal} or \textit{atom} style. \textit{Equal-style variables} compute a single numeric quantity, that can be a function of the timestep as well as of other simulation values. \textit{Atom-style variables} compute a numeric quantity for each particle, that can be a function per-atom quantities, such as the particle’s position, as well as of the timestep and other simulation values. Note that this fix stores the original coordinates of each particle (see note below) so that per-atom quantity can be used in an atom-style variable formula. See the \texttt{variable} command for details.

The first 3 variables ($v\_dx,v\_dy,v\_dz$) specified for the \texttt{variable} style are used to calculate a displacement from the particle’s original position at the time the fix was specified. The second 3 variables ($v\_vx,v\_vy,v\_vz$) specified are used to compute a velocity for each particle.

Any of the 6 variables can be specified as NULL. If both the displacement and velocity variables for a particular \texttt{x,y,z} component are specified as NULL, then the position and velocity of that component is time integrated the same as the \texttt{fix sph} command would perform, using the corresponding force component on the particle. If only the velocity variable for a component is specified as NULL, then the displacement variable will be used to set the position of the particle, and its velocity component will not be changed. If only the displacement variable for a component is specified
as NULL, then the velocity variable will be used to set the velocity of the particle, and the position of the particle will
be time integrated using that velocity.

The *units* keyword determines the meaning of the distance units used to define the *linear* velocity and *wiggle* amplitude
and *rotate* origin. This setting is ignored for the *variable* style. A *box* value selects standard units as defined by the
*units* command, e.g. velocity in Angstroms/fs and amplitude and position in Angstroms for units = real. A *lattice*
value means the velocity units are in lattice spacings per time and the amplitude and position are in lattice spacings.
The *lattice* command must have been previously used to define the lattice spacing. Each of these 3 quantities may be
dependent on the x,y,z dimension, since the lattice spacings can be different in x,y,z.

---

### 17.84.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the original coordinates of moving particles to *binary restart files*, as well as the initial timestep, so that
the motion can be continuous in a restarted simulation. See the *read_restart* command for info on how to re-specify a
fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

**Note:** Because the move positions are a function of the current timestep and the initial timestep, you cannot reset the
timestep to a different value after reading a restart file, if you expect a fix move command to work in an uninterrupted
fashion.

None of the *fix_modify* options are relevant to this fix.

This fix produces a per-atom array which can be accessed by various *output commands*. The number of columns for
each atom is 3, and the columns store the original unwrapped x,y,z coords of each particle. The per-atom values can
be accessed on any timestep.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

This fix is not invoked during *energy minimization*.

---

### 17.84.5 Restrictions

This fix is part of the DPD-SMOOTH package. It is only enabled if LAMMPS was built with that package. See the
*Build package* page for more info.

This fix requires that atoms store density and internal energy as defined by the *atom_style sph* command.

All particles in the group must be mesoscopic SPH/SDPD particles.

### 17.84.6 Related commands

*fix move, fix sph, displace_atoms*
17.84.7 Default

The option default is units = lattice.

17.85 fix_modify AtC commands

17.85.1 fix_modify AtC add_molecule command

Syntax

```bash
fix_modify <AtC fixID> add_molecule <small|large> <tag> <group-ID>
```

- AtC fixID = ID of fix atc instance
- add_molecule = name of the AtC sub-command
- `small` or `large` = can be `small` if molecule size < cutoff radius, must be `large` otherwise
- `tag` = tag for tracking a molecule
- `group-ID` = LAMMPS defined group-ID

Examples

```bash
group WATERGROUP type 1 2
fix_modify AtC add_molecule small water WATERGROUP
```

Description

Associates a tag with all molecules corresponding to a specified group.

Restrictions

None.

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC add_species`
- `fix_modify AtC remove_species`
- `fix_modify AtC remove_molecule`
**17.85.2 fix_modify AtC add_species command**

**Syntax**

```plaintext
fix_modify <AtC fixID> add_species <tag> <group|type> <ID>
```

- `AtC fixID = ID of fix atc instance`
- `add_species = name of the AtC sub-command`
- `tag = tag for tracking a species`
- `group or type = LAMMPS defined group or type of atoms`
- `ID = name of group or type number`

**Examples**

```plaintext
fix_modify AtC add_species gold type 1
group GOLDGROUP type 1
fix_modify AtC add_species gold group GOLDGROUP
```

**Description**

Associates a tag with all atoms of a specified type or within a specified group.

**Restrictions**

None.

**Related AtC commands**

- `fix_modify AtC command overview`
- `fix_modify AtC add_molecule`
- `fix_modify AtC remove_species`
- `fix_modify AtC remove_molecule`
17.85.3 fix_modify AtC atom_element_map command

Syntax

```
fix_modify <AtC fixID> atom_element_map <eulerian|lagrangian> [<frequency>]
```

• AtC fixID = ID of fix atc instance
• atom_element_map = name of the AtC sub-command
• eulerian or lagrangian = frame of reference
• frequency = frequency of updating atom-to-continuum maps based on the current configuration - (only for eulerian)

Examples

```
fix_modify AtC atom_element_map eulerian 100
```

Description

Changes frame of reference from eulerian to lagrangian or vice versa and sets the frequency for which the map from atoms to elements is reformed and all the attendant data is recalculated.

Restrictions

Cannot change map type after initialization.

Related AtC commands

• fix_modify AtC command overview

Default

lagrangian
## 17.85.4 fix_modify AtC atom_weight command

### Syntax

```plaintext
fix_modify <AtC fixID> atom_weight <method> <args>
```

- **AtC fixID** = ID of `fix atc` instance
- **atom_weight** = name of the AtC sub-command
- **method** = `constant` or `lattice` or `element` or `region` or `group` or `read_in`
  - `constant <group-ID> <value>`: atoms in specified group are assigned the constant value given
  - `lattice`: volume per atom for specified lattice type (e.g. fcc) and parameter
  - `element`: element volume divided among atoms within element
  - `region`: volume per atom determined based on the atom count in the MD regions and their volumes. Note: meaningful only if atoms completely fill all the regions.
  - `group`: volume per atom determined based on the atom count in a group and its volume
  - `node`: (undocumented)
  - `node_element`: (undocumented)
  - `read_in<filename>`: list of values for atoms are read-in from specified file

### Examples

```plaintext
fix_modify AtC atom_weight constant myatoms 11.8
fix_modify AtC atom_weight lattice
fix_modify AtC atom_weight read-in atm_wt_file.txt
```

### Description

Command for assigning the value of atomic weights used for atomic integration in atom-continuum coupled simulations.

### Restrictions

The use of the lattice option requires a lattice type and parameter is already specified.

### Related AtC commands

- [fix_modify AtC command overview](#)
Default

lattice

17.85.5 fix_modify AtC atomic_charge command

Syntax

```plaintext
fix_modify <AtC fixID> <include|omit> atomic_charge
```

- AtC fixID = ID of fix atc instance
- include or omit = switch to activate/deactivate inclusion of intrinsic atomic charge in ATC
- atomic_charge = name of the AtC sub-command

Examples

```plaintext
fix_modify AtC include atomic_charge
```

Description

Determines whether AtC tracks the total charge as a finite element field.

Restrictions

Required for: electrostatics

Related AtC commands

- fix_modify AtC command overview

Default

If the atom charge is defined, default is on, otherwise default is off.

17.85.6 fix_modify AtC boundary_dynamics command

Syntax

```plaintext
fix_modify <AtC fixID> boundary_dynamics <on|damped_harmonic|prescribed|coupled|none>
```

- AtC fixID = ID of fix atc instance
- boundary_dynamics = name of the AtC sub-command
- on or damped_harmonic prescribed coupled none
Description

Sets different schemes for controlling boundary atoms. on will integrate the boundary atoms using the velocity-verlet algorithm. damped_harmonic uses a mass/spring/dashpot for the boundary atoms with added arguments of the damping and spring constants followed by the ratio of the boundary type mass to the desired mass. prescribed forces the boundary atoms to follow the finite element displacement. coupled does the same.

Restrictions

Boundary atoms must be specified. When using swaps between internal and boundary atoms, the initial configuration must have already correctly partitioned the two.

Related AtC commands

• fix_modify AtC command overview

Default

prescribed on

17.85.7 fix_modify AtC boundary_faceset command

Syntax

```
fix_modify <AtC fixID> boundary_faceset <is|add> <faceset_name>
```

• AtC fixID = ID of fix atc instance
• boundary_faceset = name of the AtC sub-command
• is or add = select whether to select or add a faceset
• faceset_name = name of the faceset

Examples

```
fix_modify AtC boundary_faceset is obndy
```

Description

This command species the faceset name when using a faceset to compute the MD/FE boundary fluxes. The faceset must already exist.
Restrictions

This is only valid when `fe_md_boundary` is set to `faceset`.

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC fe_md_boundary`
- `fix_modify AtC mesh create_faceset box`
- `fix_modify AtC mesh create_faceset plane`

Default

None.

17.85.8 `fix_modify AtC boundary type command`

Syntax

```
fix_modify <AtC fixID> boundary type <atom-type-id>
```

- `AtC fixID = ID of fix atc instance`
- `boundary type = name of the AtC sub-command`
- `atom-type-id = type id for atoms that represent a fictitious boundary internal to the FE mesh`

Examples

```
fix_modify AtC boundary type ghost_atoms
```

Description

Command to define the atoms that represent the fictitious boundary internal to the FE mesh. For fully overlapped MD/FE domains with periodic boundary conditions no boundary atoms should be defined.

Restrictions

None.
Related AtC commands

- fix_modify AtC command overview

Default

None.

17.85.9 fix_modify AtC consistent_fe_initialization command

Syntax

```
fix_modify <AtC fixID> consistent_fe_initialization <on|off>
```

- AtC fixID = ID of fix atc instance
- consistent_fe_initialization = name of the AtC sub-command
- on or off = switch to activate/deactivate the initial setting of the FE intrinsic field to match the projected MD field

Examples

```
fix_modify AtC consistent_fe_initialization on
```

Description

Determines whether AtC initializes FE intrinsic fields (e.g., temperature) to match the projected MD values. This is particularly useful for fully overlapping simulations.

Restrictions

Can be used with: thermal, two_temperature. Cannot be used with time filtering on. Does not include boundary nodes.

Related AtC commands

- fix_modify AtC command overview

Default

Default is off
17.85.10 fix_modify AtC control localized_lambda command

Syntax

```plaintext
fix_modify <AtC fixID> control localized_lambda <on|off>
```

- AtC fixID = ID of fix atc instance
- control localized_lambda = name of the AtC sub-command
- on or off = Toggles state of localization algorithm

Examples

```plaintext
fix_modify AtC control localized_lambda on
```

Description

Turns the localization algorithms on or off for control algorithms to restrict the influence of FE coupling or boundary conditions to a region near the boundary of the MD region. Control algorithms will not affect atoms in elements not possessing faces on the boundary of the region. Flux-based control is localized via row-sum lumping while quantity control is done by solving a truncated matrix equation.

Restrictions

None.

Related AtC commands

- fix_modify AtC command overview

Default

off

17.85.11 fix_modify AtC control momentum command

Syntax

```plaintext
fix_modify <AtC fixID> control <physics_type> <solution_parameter> <value>
fraction modify AtC control momentum none
fix_modify AtC control momentum rescale <frequency>
fix_modify AtC control momentum glc_displacement
fix_modify AtC control momentum glc_velocity
fix_modify AtC control momentum hoover
fix_modify AtC control momentum flux [faceset face_set_id, interpolate]
```

- AtC fixID = ID of fix atc instance
• control = name of the AtC sub-command
• physics_type = thermal or momentum
• solution_parameter = max_iterations or tolerance
• value = solution_parameter value
• momentum option = none or rescale or glc_displacement or glc_velocity hoover or flux
• frequency = time step frequency for applying displacement and velocity rescaling
• faceset_id = id of boundary face set (optional, only for faceset)

Examples

```
fix_modify AtC control momentum none
fix_modify AtC control momentum flux faceset bndy_faces
fix_modify AtC control momentum glc_velocity
```

Description

The general version of control sets the numerical parameters for the matrix solvers used in the specified control algorithm. Many solution approaches require iterative solvers, and these methods enable users to provide the maximum number of iterations and the relative tolerance.

The control momentum version sets the momentum exchange mechanism from the finite elements to the atoms, managed through a control algorithm. rescale computes a scale factor for each atom to match the finite element temperature. hoover is a Gaussian least-constraint isokinetic thermostat enforces that the nodal restricted atomic temperature matches the finite element temperature. flux is a similar mode, but rather adds energy to the atoms based on conservation of energy.

correction_max_iterations sets the maximum number of iterations to compute the second order in time correction term for lambda with the fractional step method. The method uses the same tolerance as the controller’s matrix solver.

Restrictions

Only for be used with the specific controllers thermal or momentum. They are ignored if a lumped solution is requested. control momentum is only for be used with specific transfers: elastic rescale not valid with time filtering activated

Related AtC commands

• fix_modify AtC command overview
• fix_modify AtC control thermal
Default

- `max_iterations` is the number of rows in the matrix.
- `tolerance` is 1.0e-10.

17.85.12 `fix_modify AtC control thermal command`

Syntax

```
fix_modify <AtC fixID> control <physics_type> <solution_parameter> <value>
fix_modify <AtC fixID> control thermal <control_type> <optional_args>
fix_modify <AtC fixID> control thermal rescale <frequency>
fix_modify <AtC fixID> control thermal flux <boundary_integration_type> <faceset_id>
fix_modify <AtC fixID> control thermal correction_max_iterations <max_iterations>
```

- `AtC fixID` = ID of `fix atc` instance
- `control` = name of the AtC sub-command
- `physics_type` = `thermal` or `momentum`
- `solution_parameter` = `max_iterations` or `tolerance`
- `value` = solution_parameter value
- `control_type` = `none` or `rescale` or `hoover` or `flux`
- `frequency` = time step frequency for applying velocity rescaling
- `boundary_integration_type` = `faceset` or `interpolate` (optional)
- `faceset_id` = id of boundary face set (optional, only for `faceset`)
- `correction_max_iterations` = maximum number of iterations that will be used by iterative matrix solvers for `thermal` physics type

Examples

```
fix_modify AtC control thermal none
fix_modify AtC control thermal rescale 10
fix_modify AtC control thermal hoover
fix_modify AtC control thermal flux
fix_modify AtC control thermal flux faceset bndy_faces
fix_modify AtC control thermal correction_max_iterations 10
```
Description

The general version of control sets the numerical parameters for the matrix solvers used in the specified control algorithm. Many solution approaches require iterative solvers, and these methods enable users to provide the maximum number of iterations and the relative tolerance.

The control thermal version sets the energy exchange mechanism from the finite elements to the atoms, managed through a control algorithm. rescale computes a scale factor for each atom to match the finite element temperature. hoover is a Gaussian least-constraint isokinetic thermostat enforces that the nodal restricted atomic temperature matches the finite element temperature. flux is a similar mode, but rather adds energy to the atoms based on conservation of energy. hoover and flux allow the prescription of sources or fixed temperatures on the atoms.

correction_max_iterations sets the maximum number of iterations to compute the second order in time correction term for lambda with the fractional step method. The method uses the same tolerance as the controller’s matrix solver.

Restrictions

Only for be used with the specific controllers thermal or momentum. They are ignored if a lumped solution is requested.

control thermal is only for be used with specific transfers: thermal (rescale, hoover, flux), two_temperature (flux).

rescale not valid with time filtering activated

correction_max_iterations is only for use with thermal physics using the fractional step method.

Related AtC commands

• fix_modify AtC command overview
• fix_modify AtC control momentum

Default

• max_iterations is the number of rows in the matrix.
• tolerance is 1.0e-10.
• rescale frequency is 1
• flux boundary_integration_type is interpolate
• correction_max_iterations is 20

17.85.13 fix_modify AtC decomposition command

Syntax

fix_modify <AtC fixID> decomposition <type>

• AtC fixID = ID of fix atc instance
• decomposition = name of the AtC sub-command
• type = replicated_memory or distributed_memory
Examples

```plaintext
fix_modify AtC decomposition distributed_memory
```

Description

Command for assigning the distribution of work and memory for parallel runs. With `replicated_memory` the nodal information is replicated on each processor, and with `distributed_memory` only the owned nodal information kept on each processor. The `replicated_memory` option is most appropriate for simulations were the number of nodes is much smaller than the number of atoms.

Restrictions

None.

Related AtC commands

- `fix_modify AtC command overview`

Default

replicated_memory

17.85.14 fix_modify AtC extrinsic electron_integration command

Syntax

```
fix_modify <AtC fixID> extrinsic electron_integration <integration_type> [num_subcycle_steps]
```

- `AtC fixID` = ID of `fix atc` instance
- `extrinsic electron_integration` = name of the AtC sub-command
- `integration_type` = `explicit` or `implicit` or `steady`
- `num_subcycle_steps` = number of subcycle steps for the electron time integration (optional)

Examples

```plaintext
fix_modify AtC extrinsic electron_integration implicit
fix_modify AtC extrinsic electron_integration explicit 100
```
Description

Switches between integration schemes for the electron temperature. The number of subcycling steps used to integrate the electron temperature for one LAMMPS timestep can be manually adjusted to capture fast electron dynamics.

Restrictions

For use only with the two_temperature type of the AtC fix (see `fix atc` command)

Related AtC commands

• `fix_modify AtC command overview`

Default

`implicit` and `subcycle_steps = 1`

17.85.15 `fix_modify AtC equilibrium_start command`

Syntax

```
fix_modify <AtC fixID> equilibrium_start <on|off>
```

- `AtC fixID` = ID of `fix atc` instance
- `equilibrium_start` = name of the AtC sub-command
- `exponential` or `step` or `no_filter` = select type of filter

Examples

```
fix_modify AtC equilibrium_start on
```

Description

Starts filtered calculations assuming they start in equilibrium, i.e. perfect finite element force balance.

Restrictions

Only for use with these specific transfers: thermal, two_temperature
Related AtC commands

- fix_modify AtC command overview
- fix_modify AtC filter
- fix_modify AtC filter scale

Default

None.

17.85.16 fix_modify AtC extrinsic exchange command

Syntax

fix_modify <AtC fixID> extrinsic exchange <on|off>

- AtC fixID = ID of fix atc instance
- extrinsic exchange = name of the AtC sub-command
- on or off = set state of energy exchange

Examples

fix_modify AtC extrinsic exchange on

Description

Switches energy exchange between the MD system and the electron system on or off

Restrictions

For use only with the two_temperature type of the AtC fix (see fix atc command)

Related AtC commands

- fix_modify AtC command overview

Default

on
17.85.17 fix_modify AtC fe_md_boundary command

Syntax

```fix_modify <AtC fixID> fe_md_boundary <faceset|interpolate|no_boundary>```

- AtC fixID = ID of fix atc instance
- fe_md_boundary = name of the AtC sub-command
  - faceset or interpolate or no_boundary

Examples

```fix_modify AtC fe_md_boundary interpolate```

Description

Specifies different methods for computing fluxes between between the MD and FE integration regions. Faceset defines a faceset separating the MD and FE regions and uses finite element face quadrature to compute the flux. Interpolate uses a reconstruction scheme to approximate the flux, which is more robust but less accurate if the MD/FE boundary does correspond to a faceset. No boundary results in no fluxes between the systems being computed.

Restrictions

If faceset is used, all the AtC non-boundary atoms must lie within and completely fill the domain enclosed by the faceset.

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC mesh create_faceset box`
- `fix_modify AtC mesh create_faceset plane`

Default

`interpolate`

17.85.18 fix_modify AtC filter scale command

Syntax

```fix_modify <AtC fixID> filter scale <scale>```

- AtC fixID = ID of fix atc instance
- filter scale = name of the AtC sub-command
- scale = characteristic times scale of the filter
Examples

```
fix_modify AtC filter scale 10.0
```

Description

Sets the time scale for MD dynamics filter to construct a more appropriate continuous field.

Restrictions

Only for use with these specific transfers: thermal, two_temperature

Related AtC commands

- fix_modify AtC command overview
- fix_modify AtC filter
- fix_modify AtC filter type

Default

0.0

17.85.19 fix_modify AtC filter type command

Syntax

```
fix_modify <AtC fixID> filter type <exponential|step|no_filter>
```

- AtC fixID = ID of fix atc instance
- filter type = name of the AtC sub-command
- exponential or step or no_filter = select type of filter

Examples

```
fix_modify AtC filter type exponential
```
Description

Specifies the type of time filter used.

Restrictions

Only for use with these specific transfers: thermal, two_temperature

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC filter`
- `fix_modify AtC filter scale`

Default

None.

17.85.20 `fix_modify AtC fix command`

Syntax

```
fix_modify <AtC fixID> fix <field> <nodeset> <constant|function>
```

- `AtC fixID` = ID of fix atc instance
- `fix` = name of the AtC sub-command
- `field` = field kind name valid for type of physics: temperature or electron_temperature
- `nodeset` = name of set of nodes to apply boundary condition
- `constant` or `function` = value or name of function followed by its parameters

Examples

```
fix_modify AtC fix temperature groupNAME 10.
fix_modify AtC fix temperature groupNAME 0 0 0 10.0 0 0 1.0
```

Description

Creates a constraint on the values of the specified field at specified nodes.
Restrictions

The keyword *all* is reserved and thus not available as nodeset name.

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC unfix`

Default

None.

17.85.21 fix_modify AtC fix_flux command

Syntax

```bash
fix_modify <AtC fixID> fix_flux <field> <face_set> <value|function>
```

- **AtC fixID** = ID of `fix atc` instance
- **fix_flux** = name of the AtC sub-command
- **field** = field kind name valid for type of physics: `temperature` or `electron_temperature`
- **face_set** = name of set of element faces
- **value** or **function** = value or name of function followed by its parameters

Examples

```bash
fix_modify AtC fix_flux temperature faceSet 10.0
```

Description

Command for fixing normal fluxes e.g. `heat_flux`. This command only prescribes the normal component of the physical flux, e.g. heat (energy) flux. The units are in AtC units, i.e. derived from the LAMMPS length, time, and mass scales.

Restrictions

Only normal fluxes (Neumann data) can be prescribed.
Related AtC commands

- fix_modify AtC command overview
- fix_modify AtC unfix_flux

Default

None.

17.85.22 fix_modify AtC computes command

Syntax

```plaintext
fix_modify <AtC fixID> computes <add|delete> <per-atom compute-ID> <volume|number>
```

- AtC fixID = ID of fix atc instance
- computes = name of the AtC sub-command
- add or delete = add or delete the calculation of an equivalent continuum field for the specified per-atom compute as volume or number density quantity
- per-atom compute-ID = ID of a per-atom compute; fields can be calculated for all per-atom computes available in LAMMPS
- volume or number = select whether the created field is a per-unit-volume quantity or a per-atom quantity as weighted by kernel functions

Examples

```plaintext
compute virial all stress/atom
fix_modify AtC computes add virial volume
fix_modify AtC computes delete virial

compute centrosymmetry all centro/atom
fix_modify AtC computes add centrosymmetry number
```

Description

Calculates continuum fields corresponding to specified per-atom computes created by LAMMPS.
Restrictions

Must be used with fix atc hardy. The per-atom compute must be specified before the corresponding continuum field can be requested.

Related AtC commands

- fix_modify AtC command overview
- fix_modify AtC fields
- compute

Default

None.

17.85.23 fix_modify AtC fields command

Syntax

```
fix_modify <AtC fixID> fields <all|none>
fix_modify <AtC fixID> fields <add|delete> <list_of_fields>
```

- AtC fixID = ID of fix atc instance
- fields = name of the AtC sub-command
- all or none = output all or no fields
- add or delete = add or delete the listed output fields
- list_of_fields = one or more of the fields listed below:
  - density : mass per unit volume
  - displacement : displacement vector
  - momentum : momentum per unit volume
  - velocity : defined by momentum divided by density
  - projected_velocity : simple kernel estimation of atomic velocities
  - temperature : temperature derived from the relative atomic kinetic energy
  - kinetic_temperature : temperature derived from the full kinetic energy
  - number_density : simple kernel estimation of number of atoms per unit volume
  - stress : Cauchy stress tensor for eulerian analysis (atom_element_map), or first Piola-Kirchhoff stress tensor for lagrangian analysis
  - transformed_stress : first Piola-Kirchhoff stress tensor for eulerian analysis (atom_element_map), or Cauchy stress tensor for lagrangian analysis
  - heat_flux : spatial heat flux vector for eulerian, or referential heat flux vector for lagrangian
  - potential_energy : potential energy per unit volume
  - kinetic_energy : kinetic energy per unit volume
– thermal_energy : thermal energy (kinetic energy - continuum kinetic energy) per unit volume
– internal_energy : total internal energy (potential + thermal) per unit volume
– energy : total energy (potential + kinetic) per unit volume
– number_density : number of atoms per unit volume
– eshelby_stress : configurational stress (energy-momentum) tensor defined by [Eshelby]
– vacancy_concentration : volume fraction of vacancy content
– type_concentration : volume fraction of a specific atom type

Examples

```
fix_modify AtC fields add velocity temperature
```

Description

Allows modification of the fields calculated and output by the AtC transfer class. The commands are cumulative, e.g.:

```
fix_modify AtC fields none
fix_modify AtC fields add velocity temperature
```

will only output the velocity and temperature fields.

Restrictions

Must be used with fix atc hardy. Currently, the stress and heat flux formulas are only correct for central force potentials, e.g. Lennard-Jones and EAM but not Stillinger-Weber.

Related AtC commands

• fix_modify AtC command overview
• fix_modify AtC gradients
• fix_modify AtC rates
• fix_modify AtC computes

Default

By default, no fields are output.
17.85.24 fix_modify AtC gradients command

Syntax

```
fix_modify <AtC fixID> gradients <add|delete> <list_of_fields>
```

- **AtC fixID** = ID of `fix atc` instance
- **gradients** = name of the AtC sub-command
- **add or delete** = select whether to add or delete calculation of gradients for the listed output fields
- **list_of_fields** = one or more of the fields listed below:
  - density : mass per unit volume
  - displacement : displacement vector
  - momentum : momentum per unit volume
  - velocity : defined by momentum divided by density
  - projected_velocity : simple kernel estimation of atomic velocities
  - temperature : temperature derived from the relative atomic kinetic energy
  - kinetic_temperature : temperature derived from the full kinetic energy
  - number_density : simple kernel estimation of number of atoms per unit volume
  - stress : Cauchy stress tensor for eulerian analysis (atom_element_map), or first Piola-Kirchhoff stress tensor for lagrangian analysis
  - transformed_stress : first Piola-Kirchhoff stress tensor for eulerian analysis (atom_element_map), or Cauchy stress tensor for lagrangian analysis
  - heat_flux : spatial heat flux vector for eulerian, or referential heat flux vector for lagrangian
  - potential_energy : potential energy per unit volume
  - kinetic_energy : kinetic energy per unit volume
  - thermal_energy : thermal energy (kinetic energy - continuum kinetic energy) per unit volume
  - internal_energy : total internal energy (potential + thermal) per unit volume
  - energy : total energy (potential + kinetic) per unit volume
  - number_density : number of atoms per unit volume
  - eshelby_stress : configurational stress (energy-momentum) tensor defined by [Eshelby]
  - vacancy_concentration : volume fraction of vacancy content
  - type_concentration : volume fraction of a specific atom type
Examples

| fix_modify AtC gradients add temperature velocity stress |
| fix_modify AtC gradients delete velocity |

Description

Requests calculation and output of gradients of the fields from the AtC transfer class. These gradients will be with regard to spatial or material coordinate for Eulerian or Lagrangian analysis, respectively, as specified by fix_modify AtC atom_element_map.

Restrictions

Must be used with fix atc hardy.

Related AtC commands

- fix_modify AtC command overview
- fix_modify AtC atom_element_map
- fix_modify AtC fields
- fix_modify AtC rates

Default

None.

17.85.25 fix_modify AtC kernel command

Syntax

```
f\textit{ix}\_\textit{m}od\textit{y} <AtC \textit{fixID}> kernel <type> <parameters>
```

- AtC fixID = ID of fix atc instance
- kernel = name of the AtC sub-command
- type = step or cell or cubic_bar or cubic_cylinder or cubic_sphere or quartic_bar or quartic_cylinder or quartic_sphere
- the following parameter(s) are required for each kernel:
  - step : <radius>
  - cell : <hx> <hy> <hz> or <h>
  - cubic_bar : <half_width>
  - cubic_cylinder : <radius>
  - cubic_sphere : <radius>
  - quartic_bar : <half_width>
- quartic_cylinder : <radius>
- quartic_sphere : <radius>

Examples

```plaintext
fix_modify AtC kernel cell 1.0 1.0 1.0
fix_modify AtC kernel quartic_sphere 10.0
```

Description

Sets the localization kernel type and parameters for fix atc hardy.

Restrictions

Must be used with fix atc hardy. For bar kernel types, half-width oriented along x-direction. For cylinder kernel types, cylindrical axis is assumed to be in z-direction.

Related AtC commands

- fix_modify AtC command overview
- fix_modify AtC fields
- fix_modify AtC gradients
- fix_modify AtC rates
- fix_modify AtC computes

Default

None.

17.85.26 fix_modify AtC on_the_fly command

Syntax

```plaintext
fix_modify <AtC fixID> on_the_fly <bond|kernel> <on|off>
```

- AtC fixID = ID of fix atc instance
- on_the_fly = name of the AtC sub-command
- bond or kernel = specifies on-the-fly calculation of bond or kernel matrix elements
- on or off = activate or discontinue on-the-fly mode
Examples

```
fix_modify AtC on_the_fly bond on
fix_modify AtC on_the_fly kernel
fix_modify AtC on_the_fly kernel off
```

Description

Overrides normal mode of pre-calculating and storing bond pair-to-node and kernel atom-to-node matrices. If activated, it will calculate elements of these matrices during repeated calls of field computations (i.e. “on-the-fly”) and not store them for future use. The `on` flag is optional - if omitted, `on_the_fly` will be activated for the specified matrix. Can be deactivated using the `off` flag.

Restrictions

Must be used with `fix atc hardy`.

Related AtC commands

- `fix_modify AtC command overview`

Default

By default, on-the-fly calculation is not active (i.e. `off`). However, THE code does a memory allocation check to determine if it can store all needed bond and kernel matrix elements. If this allocation fails, on-the-fly will be activated.

17.85.27 fix_modify AtC rates command

Syntax

```
fix_modify <AtC fixID> rates <add|delete> <list_of_fields>
```

- `AtC fixID` = ID of `fix atc` instance
- `rates` = name of the AtC sub-command
- `add` or `delete` = select whether to add or delete calculation of rates for the listed output fields
- `list_of_fields` = one or more of the fields listed below:
  - `density` : mass per unit volume
  - `displacement` : displacement vector
  - `momentum` : momentum per unit volume
  - `velocity` : defined by momentum divided by density
  - `projected_velocity` : simple kernel estimation of atomic velocities
  - `temperature` : temperature derived from the relative atomic kinetic energy
  - `kinetic_temperature` : temperature derived from the full kinetic energy
– number_density : simple kernel estimation of number of atoms per unit volume
– stress : Cauchy stress tensor for eulerian analysis (atom_element_map), or first Piola-Kirchhoff stress tensor for lagrangian analysis
– transformed_stress : first Piola-Kirchhoff stress tensor for eulerian analysis (atom_element_map), or Cauchy stress tensor for lagrangian analysis
– heat_flux : spatial heat flux vector for eulerian, or referential heat flux vector for lagrangian
– potential_energy : potential energy per unit volume
– kinetic_energy : kinetic energy per unit volume
– thermal_energy : thermal energy (kinetic energy - continuum kinetic energy) per unit volume
– internal_energy : total internal energy (potential + thermal) per unit volume
– energy : total energy (potential + kinetic) per unit volume
– number_density : number of atoms per unit volume
– eshelby_stress : configurational stress (energy-momentum) tensor defined by [Eshelby]
– vacancy_concentration : volume fraction of vacancy content
– type_concentration : volume fraction of a specific atom type

Examples

```plaintext
fix_modify AtC rates add temperature velocity stress
fix_modify AtC rates delete stress
```

Description

Requests calculation and output of rates (time derivatives) of the fields from the AtC transfer class. For Eulerian analysis (see `fix_modify AtC atom_element_map`) these rates are the partial time derivatives of the nodal fields, not the full (material) time derivatives.

Restrictions

Must be used with `fix atc hardy`.

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC atom_element_map`
- `fix_modify AtC fields`
- `fix_modify AtC fields`
17.85.28 fix_modify AtC initial command

Syntax

```
fix_modify <AtC fixID> initial <field> <nodeset> <constant|function>
```

- `AtC fixID` = ID of `fix atc` instance
- `initial` = name of the AtC sub-command
- `field` = field kind name valid for type of physics: `temperature` or `electron_temperature`
- `nodeset` = name of set of nodes to apply initial condition
- `constant` or `function` = value or name of function followed by its parameters

Examples

```
fix_modify AtC initial temperature groupNAME 10.
```

Description

Sets the initial values for the specified field at the specified nodes.

Restrictions

The keyword `all` is reserved and thus not available as nodeset name.

Related AtC commands

- `fix_modify AtC command overview`
• element_set_name = name of element set defining internal region, or off

Examples

```c
fix_modify AtC internal_element_set myElementSet
fix_modify AtC internal_element_set off
```

Description

Enables AtC to base the region for internal atoms to be an element set. If no ghost atoms are used, all the AtC atoms must be constrained to remain in this element set by the user, e.g., with walls. If boundary atoms are used in conjunction with Eulerian atom maps AtC will partition all atoms of a boundary or internal type to be of type internal if they are in the internal region or to be of type boundary otherwise.

Restrictions

If boundary atoms are used in conjunction with Eulerian atom maps, the Eulerian reset frequency must be an integer multiple of the Lammmps reneighbor frequency.

Related AtC commands

• fix_modify AtC command overview
• fix_modify AtC atom_element_map
• fix_modify AtC boundary type

Default

off

17.85.30 fix_modify AtC internal_quadrature command

Syntax

```c
fix_modify <AtC_fixID> internal_quadrature <on|off> [region]
```

• AtC_fixID = ID of fix atc instance
• internal_quadrature = name of the AtC sub-command
• on or off = select whether internal quadrature is enabled or not
• region = treat finite elements as within MD region (optional)
Examples

```plaintext
fix_modify AtC internal_quadrature off
```

Description

Command to use or not use atomic quadrature on internal elements fully filled with atoms. By turning the internal quadrature off these elements do not contribute to the governing PDE and the fields at the internal nodes follow the weighted averages of the atomic data.

Optional region tag specifies which finite element nodes will be treated as being within the MD region. This option is only valid with internal_quadrature off.

Related AtC commands

- `fix_modify AtC command overview`

Default

on.

17.85.31 fix_modify AtC kernel_bandwidth command

Syntax

```plaintext
fix_modify <AtC fixID> kernel_bandwidth <value>
```

- AtC fixID = ID of `fix_atc` instance
- kernel_bandwidth = name of the AtC sub-command
- value = new bandwidth value

Examples

```plaintext
fix_modify AtC kernel_bandwidth 8
```

Description

Sets a maximum parallel bandwidth for the kernel functions during parallel communication. If the command is not issued, the default will be to assume the bandwidth of the kernel matrix corresponds to the number of sampling locations.
Restrictions

Only is used if kernel functions are being used.

Related AtC commands

- fix_modify AtC command overview

Default

Number of sample locations.

17.85.32 fix_modify AtC control lumped_lambda_solve command

Syntax

```
fix_modify <AtC fixID> control lumped_lambda_solve <on|off>
```

- AtC fixID = ID of fix atc instance
- control lumped_lambda_solve = name of the AtC sub-command
- on or off = Toggles state of lumped matrix

Examples

```
fix_modify AtC control lumped_lambda_solve on
```

Description

Command select whether to use or not use lumped matrix for lambda solve.

Restrictions

None.

Related AtC commands

- fix_modify AtC command overview
Default
off

17.85.33 fix_modify AtC control mask_direction command

Syntax

```
f\text{ix\_modify} \text{\<AtC\ fixID\>} \text{\ control mask\_direction} \text{\<direction\>} \text{\<on|off\>}
```

- AtC fixID = ID of fix atc instance
- control mask_direction = name of the AtC sub-command
- direction = select direction
- on or off = Toggles state

Examples

```
f\text{ix\_modify} \text{\ AtC \ control mask\_direction} 0 \text{\ on}
```

Description

Command to mask out certain dimensions from the atomic regulator

Restrictions

None.

Related AtC commands

- fix_modify AtC command overview

17.85.34 fix_modify AtC mass_matrix command

Syntax

```
f\text{ix\_modify} \text{\<AtC\ fixID\>} \text{\ mass\_matrix} \text{\<fe\|md\_fe\>}
```

- AtC fixID = ID of fix atc instance
- mass_matrix = name of the AtC sub-command
- fe or md_fe = activate/deactivate using the FE mass matrix in the MD region
Examples

\textbf{fix_modify} AtC mass_matrix fe

Description

Determines whether AtC uses the FE mass matrix based on Gaussian quadrature or based on atomic quadrature in the MD region. This is useful for fully overlapping simulations to improve efficiency.

Restrictions

Should not be used unless the FE region is contained within the MD region, otherwise the method will be unstable and inaccurate.

Related AtC commands

- \textit{fix_modify AtC command overview}

Default

\textit{md_fe}

17.85.35 fix_modify AtC material command

Syntax

\texttt{fix_modify <AtC fixID> material <elementset_name> <material_id>}

- AtC fixID = ID of \textit{fix atc} instance
- material = name of the AtC sub-command
- elementset_name = name of the elementset
- material_id = ID of the material

Examples

\texttt{fix_modify AtC material gap_region 1}
Description

Sets the material model in `elementset_name` to be of type `material_id`.

Restrictions

The element set must already be created and the material must be specified in the material file given the the atc fix on construction.

Related AtC commands

- `fix_modify AtC command overview`

Default

All elements default to the first material in the material file.

17.85.36 fix_modify AtC mesh add_to_nodeset command

Syntax

```
fix_modify <AtC fixID> mesh add_to_nodeset <id> <xmin> <xmax> <ymin> <ymax> <zmin> <zmax>
```

- `AtC fixID` = ID of `fix atc` instance
- `mesh create_nodeset` = name of the AtC sub-command
- `id` = id to assign to the collection of FE nodes
- `<xmin> <xmax> <ymin> <ymax> <zmin> <zmax>` = coordinates of the bounding box that contains the desired nodes to be added

Examples

```
fix_modify AtC mesh add_to_nodeset lbc -12.1 -11.9 -12 12 -12 12
```

Description

Command to add nodes to an already existing FE nodeset.
Restrictions

None

Related AtC commands

- fix_modify AtC command overview
- fix_modify AtC mesh create_nodeset

Default

Coordinates are assumed to be in lattice units.

17.85.37 fix_modify AtC mesh create command

Syntax

```
fix_modify <AtC fixID> mesh create <nx> <ny> <nz> <region-ID> <f|p> <f|p> <f|p>
```

- AtC fixID = ID of fix atc instance
- mesh create = name of the AtC sub-command
- nx, ny, nz = number of elements in x-, y-, and z-direction
- region-ID = ID of region that is to be meshed
- f or p = periodicity flags for x-, y-, and z-direction

Examples

```
fix_modify AtC mesh create 10 1 1 feRegion p p p
```

Description

Creates a uniform mesh in a rectangular region.

Restrictions

Creates only uniform rectangular grids in a rectangular region
Related AtC commands

- fix_modify AtC command overview
- fix_modify AtC mesh quadrature

Default

When created, the mesh defaults to gauss2 (2-point Gaussian) quadrature. Use the fix_modify AtC mesh quadrature command to change the quadrature style.

17.85.38 fix_modify AtC mesh create_elementset command

Syntax

```
fix_modify <AtC fixID> mesh create_elementset <id> <xmin> <xmax> <ymin> <ymax> <zmin> <zmax>
```

- AtC fixID = ID of fix atc instance
- mesh create_elementset = name of the AtC sub-command
- id = id to assign to the collection of FE nodes
- <xmin> <xmax> <ymin> <ymax> <zmin> <zmax> = coordinates of the bounding box that contains only the desired elements

Examples

```
fix_modify AtC mesh create_elementset middle -4.1 4.1 -100 100 -100 1100
```

Description

Command to assign an id to a set of FE elements to be used subsequently in defining material and mesh-based operations.

Restrictions

Only viable for rectangular grids.

Related AtC commands

- fix_modify AtC command overview
- fix_modify AtC mesh delete_elements
- fix_modify AtC mesh nodeset_to_elementset
**Default**
Coordinates are assumed to be in lattice units.

### 17.85.39 `fix_modify AtC mesh create_faceset box command`  
**Syntax**

| fix_modify | AtC fixID > mesh create_faceset <id> box <xmin> <xmax> <ymin> <ymax> <zmin> <zmax> <in|out> [units] |
|------------|----------------------------------------------------------------------------------------------------|

- `AtC fixID` = ID of `fix atc` instance
- `mesh create_faceset` = name of the AtC sub-command
- `id` = id to assign to the collection of FE faces
- `box` = use bounding box to define FE faces
- `<xmin> <xmax> <ymin> <ymax> <zmin> <zmax>` = coordinates of the bounding box that is coincident with the desired FE faces
- `<in|out>` = “in” gives inner faces to the box, “out” gives the outer faces to the box
- `units` = option to specify real as opposed to lattice units

#### Examples

```
fix_modify AtC mesh create_faceset obndy box -4.0 4.0 -12 12 -12 12 out
```

**Description**

Command to assign an id to a set of FE faces.

**Restrictions**

Only viable for rectangular grids.

**Related AtC commands**

- `fix_modify AtC command overview`
- `fix_modify AtC mesh create_faceset plane`
The default options are units = lattice and the use of outer faces.

### 17.85.40 fix_modify AtC mesh create_faceset plane command

**Syntax**

```
fix_modify <AtC fixID> mesh create_faceset <id> plane <x|y|z> <val1> <x|y|z> <lval2> <uval2> [units]
```

- **AtC fixID** = ID of *fix atc* instance
- **mesh create_faceset** = name of the AtC sub-command
- **id** = id to assign to the collection of FE faces
- **plane** = use plane to define faceset
- **<val1>,<lval2>,<uval2>** = plane is specified as the x|y|z=val1 plane bounded by the segments x|y|z = [lval2,uval2]
- **units** = option to specify real as opposed to lattice units

**Examples**

```
fix_modify AtC mesh create_faceset xyplane plane y 0 x -4 0
```

**Description**

Command to assign an id to a set of FE faces.

**Restrictions**

Only viable for rectangular grids.

**Related AtC commands**

- `fix_modify AtC command overview`
- `fix_modify AtC mesh create_faceset box`

**Default**

The default options are units = lattice.
17.85.41 **fix_modify AtC mesh create_nodeset command**

**Syntax**

```plaintext
fix_modify <AtC_fixID> mesh create_nodeset <id> <xmin> <xmax> <ymin> <ymax> <zmin> <zmax>
```

- `AtC_fixID` = ID of `fix_atc` instance
- `mesh create_nodeset` = name of the AtC sub-command
- `id` = id to assign to the collection of FE nodes
- `<xmin> <xmax> <ymin> <ymax> <zmin> <zmax>` = coordinates of the bounding box that contains only the desired nodes

**Examples**

```plaintext
fix_modify AtC mesh create_nodeset lbc -12.1 -11.9 -12 12 -12 12
```

**Description**

Command to assign an id to a set of FE nodes to be used subsequently in defining boundary conditions.

**Restrictions**

None

**Related AtC commands**

- `fix_modify AtC command overview`
- `fix_modify AtC mesh add_to_nodeset`

**Default**

Coordinates are assumed to be in lattice units.

17.85.42 **fix_modify AtC mesh delete_elements command**

**Syntax**

```plaintext
fix_modify <AtC_fixID> mesh delete_elements <id>
```

- `AtC_fixID` = ID of `fix_atc` instance
- `mesh delete_elements` = name of the AtC sub-command
- `id` = id of the element set

17.85. **fix_modify AtC commands**
Examples

```plaintext
fix_modify AtC mesh delete_elements gap
```

Description

Deletes a group of elements from the mesh.

Restrictions

None.

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC mesh create_elementset`
- `fix_modify AtC mesh nodeset_to_elementset`

Default

None.

17.85.43 fix_modify AtC mesh nodeset_to_elementset command

Syntax

```plaintext
fix_modify <AtC fixID> mesh nodeset_to_elementset <nodeset_id> <elementset_id> <max/min>
```

- AtC fixID = ID of `fix atc` instance
- mesh nodeset_to_elementset = name of the AtC sub-command
- nodeset_id = id of desired nodeset from which to create the elementset
- elementset_id = id to assign to the collection of FE elements
- `<max/min>` = flag to choose either the maximal or minimal elementset

Examples

```plaintext
fix_modify AtC mesh nodeset_to_elementset myNodeset myElementset min
```
Description

Command to create an elementset from an existing nodeset. Either the minimal element set of elements with all nodes in the set, or maximal element set with all elements with at least one node in the set, can be created.

Restrictions

None.

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC mesh create_elementset`
- `fix_modify AtC mesh delete_elements`

Default

Unless specified, the maximal element set is created.

17.85.44 fix_modify AtC mesh output command

Syntax

```
fix_modify <AtC fixID> mesh output <file_prefix>
```

- `AtC fixID` = ID of `fix atc` instance
- `mesh output` = name of the AtC sub-command
- `file_prefix` = prefix of various generated output files

Examples

```
fix_modify AtC mesh output meshData
```

Description

Command to output mesh and associated data: nodesets, facesets, and elementsets. This data is only output once upon initialization since currently the mesh is static. Creates binary (EnSight, “gold” format) output of mesh data.
Restrictions

None.

Related AtC commands

• fix_modify AtC command overview

Default

None.

17.85.45 fix_modify AtC mesh quadrature command

Syntax

fix_modify <AtC fixID> mesh quadrature <quad>

• AtC fixID = ID of fix atc instance
• mesh quadrature = name of the AtC sub-command
• quad = nodal or gauss1 or gauss2 or gauss3 or face

Examples

fix_modify AtC mesh quadrature face

Description

(Re-)assigns the quadrature style for an existing mesh. When a mesh is created its quadrature method defaults to gauss2. Use this call to change it after the fact.

Restrictions

None.

Related AtC commands

• fix_modify AtC command overview
• fix_modify AtC mesh create
**Default**

None.

### 17.85.46 fix_modify AtC mesh read command

**Syntax**

```plaintext
fix_modify <AtC fixID> mesh read <f|p> <f|p> <f|p>
```

- AtC fixID = ID of `fix atc` instance
- mesh read = name of the AtC sub-command
- filename = name of the file containing the mesh to be read
- f or p = periodicity flags for x-, y-, and z-direction (optional)

**Examples**

```plaintext
fix_modify AtC mesh read myComponent.mesh p p p
fix_modify AtC mesh read myOtherComponent.exo
```

**Description**

Reads a mesh from a text or exodus file, and assigns periodic boundary conditions if needed.

**Restrictions**

None

**Related AtC commands**

- `fix_modify AtC command overview`
- `fix_modify AtC mesh create`
- `fix_modify AtC mesh write`

**Default**

Periodicity flags are set to false (f) by default.
17.85.47 fix_modify AtC mesh write command

Syntax

fix_modify <AtC fixID> mesh write <f|p> <f|p> <f|p>

- AtC fixID = ID of fix atc instance
- mesh write = name of the AtC sub-command
- filename = name of the file containing the mesh to be write

Examples

```
fix_modify AtC mesh write myMesh.mesh
```

Description

Writes a mesh to a text file.

Restrictions

None

Related AtC commands

- fix_modify AtC command overview
- fix_modify AtC mesh create
- fix_modify AtC mesh read

Default

None.

17.85.48 fix_modify AtC output command

Syntax

fix_modify <AtC fixID> output <filename_prefix> <frequency> [text|full_...
fix_modify <AtC fixID> output index [step|time]

- AtC fixID = ID of fix atc instance
- output or output index = name of the AtC sub-command
- filename_prefix = prefix for data files (for output)
- frequency = frequency of output in timesteps (for output)
• optional keywords for `output`:
  – `text` = creates text output of index, step and nodal variable values for unique nodes
  – `full_text` = creates text output index, nodal id, step, nodal coordinates and nodal variable values for unique and image nodes
  – `binary` = creates binary EnSight output
  – `vector_components` = outputs vectors as scalar components
  – `tensor_components` = outputs tensor as scalar components (for use with ParaView)

• `step` or `time` = index output by step or by time (for `output index`)

**Examples**

```plaintext
fix_modify AtC output heatFE 100
fix_modify AtC output hardyFE 1 text tensor_components
fix_modify AtC output hardyFE 10 text binary tensor_components
fix_modify AtC output index step
```

**Description**

Creates text and/or binary (EnSight, “gold” format) output of nodal/mesh data which is transfer/physics specific. Output indexing by step or time is possible.

**Restrictions**

None.

**Related AtC commands**

- `fix_modify AtC command overview`
- `fix atc command`

**Default**

No default format. Output indexed by time.

**17.85.49 `fix_modify AtC output boundary_integral command`**

**Syntax**

```plaintext
fix_modify <AtC fixID> output boundary_integral <fieldname> faceset [name]
```

- `AtC fixID` = ID of `fix atc` instance
- `output boundary_integral` = name of the AtC sub-command
- `fieldname` = name of hardy field

**17.85. `fix_modify AtC commands`**
• faceset = required keyword
• name= name of faceset

Examples

```text
fix_modify AtC output boundary_integral stress faceset loop1
```

Description

Calculates a surface integral of the given field dotted with the outward normal of the faces and puts output in the “GLOBALS” file.

Restrictions

Must be used with the hardy/field type of fix atc

Related AtC commands

• fix_modify AtC command overview

Default

None.

17.85.50 fix_modify AtC output contour_integral command

Syntax

```text
fix_modify <AtC_fixID> output contour_integral <fieldname> faceset <name> [axis [x|y|z]]
```

• AtC fixID = ID of fix atc instance
• output contour_integral = name of the AtC sub-command
• fieldname = name of hardy field
• faceset = required keyword
• name = name of faceset
• axis x or axis y or axis z = (optional)
Examples

```plaintext
fix_modify AtC output contour_integral stress faceset loop1
```

Description

Calculates a surface integral of the given field dotted with the outward normal of the faces and puts output in the “GLOBALS” file.

Restrictions

Must be used with the hardy/field type of `fix atc`

Related AtC commands

- `fix_modify AtC command overview`

Default

None.

17.85.51 `fix_modify AtC output nodeset command`

Syntax

```plaintext
fix_modify <AtC fixID> output nodeset <nodeset_name> <operation>
```

- `AtC fixID` = ID of `fix atc` instance
- `output nodeset` = name of the AtC sub-command
- `nodeset_name` = name of nodeset to be operated on
- `operation` = `sum`
  - `sum` = creates nodal sum over nodes in specified nodeset

Examples

```plaintext
fix_modify AtC output nodeset nset1 sum
```
Description

Performs operation over the nodes belonging to specified nodeset and outputs resulting variable values to GLOBALS file.

Restrictions

None.

Related AtC commands

- fix_modify AtC command overview

Default

None.

17.85.52 fix_modify AtC output volume_integral command

Syntax

```plaintext
fix_modify <AtC fixID> output volume_integral <elementset_name> <field>
```

- AtC fixID = ID of fix atc instance
- output volume_integral = name of the AtC sub-command
- elementset_name= name of elementset to be integrated over
- fieldname = name of field to integrate

Examples

```plaintext
fix_modify AtC output volume_integral eset1 mass_density
```

Description

Performs volume integration of specified field over elementset and outputs resulting variable values to GLOBALS file.
Restrictions

None.

Related AtC commands

- fix_modify AtC command overview
- fix atc command

Default

None.

17.85.53 fix_modify AtC pair_interactions command

17.85.54 fix_modify AtC bond_interactions command

Syntax

fix_modify <AtC fixID> pair_interactions <on|off>
fix_modify <AtC fixID> bond_interactions <on|off>

- AtC fixID = ID of fix atc instance
- pair_interactions or bond_interactions = name of the AtC sub-command
- on or off = activate or deactivate

Examples

fix_modify AtC pair_interactions off
fix_modify AtC bond_interactions on

Description

Include bonds and/or pairs in stress and heat flux computations.

Restrictions

None.
Related AtC commands

• fix_modify AtC command overview

Default

pair_interactions: on, bond_interactions: off

17.85.55 fix_modify AtC poisson_solver command

Syntax

\[
\text{fix_modify} \; \langle \text{AtC fixID} \rangle \; \text{poisson} \_\text{solver} \; \text{mesh create} \; \langle nx \rangle \; \langle ny \rangle \; \langle nz \rangle \; \langle \text{region-ID} \rangle \; \langle f|p \rangle \; \langle f|p \rangle
\]

• AtC fixID = ID of fix atc instance
• poisson_solver = name of the AtC sub-command
• \( nx \) \( ny \) \( nz \) = number of elements in x, y, and z
• region-id = id of region to be meshed
• \( f \) or \( p \) = periodicity flags for x, y, and z

Examples

\[
\text{fix_modify} \; \text{AtC poisson} \_\text{solver} \; \text{mesh create} \; 10 \; 1 \; 1 \; \text{feRegion} \; p \; p \; p
\]

Description

Creates a uniform mesh in a rectangular region.

Restrictions

Creates only uniform rectangular grids in rectangular regions.

Related AtC commands

• fix_modify AtC command overview
Default

None.

17.85.56 fix_modify AtC read_restart command

Syntax

```latex
fix_modify <AtC fixID> read_restart <file_name>
```

- AtC fixID = ID of fix atc instance
- read_restart = name of the AtC sub-command
- file_name = name of AtC restart file

Examples

```latex
fix_modify AtC read_restart restart.mydata.AtC
```

Description

Reads the current state of the AtC fields from a named text-based restart file.

Restrictions

The restart file only contains fields and their time derivatives. The reference positions of the atoms and the commands that initialize the fix are not saved e.g. an identical mesh containing the same atoms will have to be recreated.

Related AtC commands

- fix_modify AtC command overview

### 17.85.58 fix_modify AtC remove_source command

**Syntax**

```plaintext
fix_modify <AtC fixID> remove_source <field> <element_set>
```

- `AtC fixID = ID of fix atc instance`
- `remove_source = name of the AtC sub-command`
- `field = field kind name valid for type of physics: temperature or electron_temperature`
- `element_set = name of set of elements`

**Examples**

```plaintext
fix_modify AtC remove_source temperature groupNAME
```
Description

Remove a domain source.

Restrictions

The keyword *all* is reserved and thus not available as element_set name.

Related AtC commands

- fix_modify AtC command overview

17.85.60 fix_modify AtC reset_atomic_reference_positions command

Syntax

```plaintext
fix_modify <AtC fixID> reset_atomic_reference_positions
```

- AtC fixID = ID of `fix atc` instance
- reset_atomic_reference_positions = name of the AtC sub-command

Examples

```plaintext
fix_modify AtC reset_atomic_reference_positions
```

Description

Resets the atomic positions ATC uses to perform point to field operations. In can be used to use perfect lattice sites in ATC but a thermalized or deformed lattice in LAMMPS.

Restrictions

None.

Related AtC commands

- fix_modify AtC command overview
Default

17.85.61 fix_modify AtC reset_time command

Syntax

```plaintext
fix_modify <AtC fixID> reset_time <value>
```

- AtC fixID = ID of `fix atc` instance
- reset_time = name of the AtC sub-command
- value = new time value

Examples

```plaintext
fix_modify AtC reset_time 0.0
```

Description

Resets the simulation time counter.

Restrictions

None.

Related AtC commands

- `fix_modify AtC command overview`

Default

None

17.85.62 fix_modify AtC sample_frequency command

Syntax

```plaintext
fix_modify <AtC fixID> sample_frequency <freq>
```

- AtC fixID = ID of `fix atc` instance
- sample_frequency = name of the AtC sub-command
- freq = frequency to sample fields in number of steps
Examples

```
fix_modify AtC sample_frequency 10
```

Description

Specifies a frequency at which fields are computed for the case where time filters are being applied.

Restrictions

Must be used with `fix atc hardy` and is only relevant when time filters are being used.

Related AtC commands

• `fix_modify AtC command overview`

Default

None.

17.85.63 `fix_modify AtC set reference_potential_energy` command

Syntax

```
fix_modify <AtC fixID> set reference_potential_energy [value|filename]
```

• AtC fixID = ID of `fix atc` instance
• set reference_potential_energy = name of the AtC sub-command
• value = optional user specified zero point for PE in native LAMMPS energy units
• filename = optional user specified string for file of nodal PE values to be read-in

Examples

```
fix_modify AtC set reference_potential_energy
fix_modify AtC set reference_potential_energy -0.05
fix_modify AtC set reference_potential_energy myPEvalues
```
Description

Used to set various quantities for the post-processing algorithms. It sets the zero point for the potential energy density using the value provided for all nodes, or from the current configuration of the lattice if no value is provided, or values provided within the specified filename.

Restrictions

Must be used with *fix atc hardy* or *fix atc field*.

Related AtC commands

- *fix_modify AtC command overview*

Default

Defaults to the LAMMPS zero point i.e. isolated atoms.

17.85.64 fix_modify AtC source command

Syntax

```plaintext
fix_modify <AtC fixID> source <field> <element_set> <value|function>
```

- AtC fixID = ID of *fix atc* instance
- source = name of the AtC sub-command
- field = field kind name valid for type of physics: *temperature* or *electron_temperature*
- element_set = name of set of elements
- value or function = value or name of function followed by its parameters

Examples

```plaintext
fix_modify AtC source temperature middle temporal_ramp 10.0 0.0
```

Description

Add domain sources to the mesh. The units are consistent with LAMMPS’s units for mass, length and time and are defined by the PDE being solved, e.g. for thermal transfer the balance equation is for energy and source is energy per time.
Restrictions
The keyword *all* is reserved and thus not available as element_set name.

Related AtC commands

- *fix_modify AtC command overview*
- *fix_modify AtC remove_source*

Default
None.

17.85.65 fix_modify AtC source_integration command

Syntax

```
fix_modify <AtC fixID> source_integration <fe|atom>
```

- AtC fixID = ID of *fix atc* instance
- source_integration = name of the AtC sub-command
- *fe* or *atom* = (undocumented)

Examples

```
fix_modify AtC source_integration atom
```

Description
(undocumented)

Restrictions
None.

Related AtC commands

- *fix_modify AtC command overview*
Default

Default is \textit{fe}

\textbf{17.85.66 \textit{fix\_modify AtC temperature\_definition command}}

\textbf{Syntax}

\begin{verbatim}
fix\_modify <AtC fixID> temperature\_definition <kinetic|total>
\end{verbatim}

- AtC fixID = ID of \textit{fix atc} instance
- temperature\_definition = name of the AtC sub-command
- \textit{kinetic} or \textit{total} = (undocumented)

\textbf{Examples}

\begin{verbatim}
fix\_modify AtC temperature\_definition kinetic
\end{verbatim}

\textbf{Description}

Change the definition for the atomic temperature used to create the finite element temperature. The kinetic option is based only on the kinetic energy of the atoms while the total option uses the total energy (kinetic + potential) of an atom.

\textbf{Restrictions}

This command is only valid when using thermal coupling. Also, while not a formal restriction, the user should ensure that associating a potential energy with each atom makes physical sense for the total option to be meaningful.

\textbf{Related AtC commands}

- \textit{fix\_modify AtC command overview}

\textbf{Default}

\textit{kinetic}

\textbf{17.85.67 \textit{fix\_modify AtC filter command}}

\textbf{Syntax}

\begin{verbatim}
fix\_modify <AtC fixID> filter <on|off|equilibrate>
\end{verbatim}

- AtC fixID = ID of \textit{fix atc} instance
- filter = name of the AtC sub-command
• on or off or equilibrate = Select state of filter

Examples

```plaintext
fix_modify AtC filter on
```

Description

Filters the MD dynamics to construct a more appropriate continuous field. Equilibrating first filters the time derivatives without changing the dynamics to provide a better initial condition to the filtered dynamics.

Restrictions

Only for use with these specific transfers: thermal, two_temperature

Related AtC commands

• fix_modify AtC command overview
• fix_modify AtC filter scale
• fix_modify AtC equilibrium_start

Default

off

17.85.68 fix_modify AtC time_integration command

Syntax

```plaintext
fix_modify <AtC fixID> time_integration <descriptor>
```

• AtC fixID = ID of fix atc instance
• time_integration = name of the AtC sub-command
• descriptor = gear or fractional_step or verlet

Examples

```plaintext
fix_modify AtC time_integration fractional_step
```
Description

Command to select the thermal or momentum time integration.

Options for thermal time integration:

- **gear**  atomic velocity update with second order Verlet, nodal temperature update with third or fourth order Gear, thermostats based on controlling power
- **fractional_step**  atomic velocity update with second order Verlet, mixed nodal temperature update, 3/4 Gear for continuum and 2 Verlet for atomic contributions, thermostats based on controlling discrete energy changes

Options for momentum time integration:

- **verlet**  atomic velocity update with second order Verlet, nodal temperature update with second order Verlet, kinetostats based on controlling force
- **fractional_step**  atomic velocity update with second order Verlet, mixed nodal momentum update, second order Verlet for continuum and exact second order Verlet for atomic contributions, kinetostats based on controlling discrete momentum changes
- **gear**  atomic velocity update with second order Verlet, nodal temperature update with third or fourth order Gear, kinetostats based on controlling power.

Restrictions

None.

Related AtC commands

- fix_modify AtC command overview

Default

17.85.69 fix_modify AtC track_displacement command

Syntax

```
fix_modify <AtC fixID> track_displacement <on|off>
```

- AtC fixID = ID of fix atc instance
- track_displacement = name of the AtC sub-command
- on or off = (undocumented)
Examples

```plaintext
fix_modify AtC track_displacement on
```

Description

Determines whether displacement is tracked or not. For solids problems this is a useful quantity, but for fluids it is not relevant.

Restrictions

Some constitutive models require the displacement field.

Related AtC commands

- `fix_modify AtC command overview`

Default

`on`

17.85.70  fix_modify AtC unfix command

Syntax

```plaintext
fix_modify <AtC fixID> unfix <field> <nodeset>
```

- `AtC fixID = ID of fix atc instance`
- `unfix = name of the AtC sub-command`
- `field = field kind name valid for type of physics: temperature or electron_temperature`
- `nodeset = name of set of nodes to apply boundary condition`

Examples

```plaintext
fix_modify AtC unfix temperature groupNAME
```

Description

Removes constraint on field values for specified nodes.
Restrictions

The keyword *all* is reserved and thus not available as nodeset name.

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC fix`

Default

None.

17.85.71 fix_modify AtC unfix_flux command

Syntax

```
fix_modify <AtC_fixID> unfix_flux <field> <face_set> <value|function>
```

- `AtC_fixID` = ID of `fix atc` instance
- `unfix_flux` = name of the AtC sub-command
- `field` = field kind name valid for type of physics: `temperature` or `electron_temperature`
- `face_set` = name of set of element faces

Examples

```
fix_modify AtC unfix_flux temperature faceSet
```

Description

Command for removing prescribed normal fluxes e.g. heat_flux, stress.

Restrictions

None.

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC fix_flux`
17.85.72 fix_modify AtC write_atom_weights command

Syntax

```
fix_modify <AtC fixID> write_atom_weights <filename> <frequency>
```

- **AtC fixID** = ID of `fix atc` instance
- **write_atom_weights** = name of the AtC sub-command
- **filename** = name of file that atomic weights are written to
- **frequency** = how often writes will occur

Examples

```
fix_modify AtC write_atom_weights atm_wt_file.txt 10
```

Description

Command for writing the values of atomic weights to a specified file.

Restrictions

None.

Related AtC commands

- `fix_modify AtC command overview`

17.85.73 fix_modify AtC write_restart command

Syntax

```
fix_modify <AtC fixID> write_restart <file_name>
```

- **AtC fixID** = ID of `fix atc` instance
- **write_restart** = name of the AtC sub-command
- **file_name** = name of AtC restart file
Examples

```plaintext
fix_modify AtC write_restart restart.mydata.AtC
```

Description

Dumps the current state of the fields to a named text-based restart file. This done when the command is invoked and not repeated, unlike the otherwise similar LAMMPS command.

Restrictions

None.

Related AtC commands

- `fix_modify AtC command overview`
- `fix_modify AtC read_restart`

Default

None.

17.86 fix mol/swap command

17.86.1 Syntax

```plaintext
fix ID group-ID mol/swap N X itype jtype seed T keyword value ...
```

- ID, group-ID are documented in `fix` command
- atom/swap = style name of this fix command
- N = invoke this fix every N steps
- X = number of swaps to attempt every N steps
- itype, jtype = two atom types to swap with each other
- seed = random # seed (positive integer)
- T = scaling temperature of the MC swaps (temperature units)
- zero or more keyword/value pairs may be appended to args
- keyword = ke
  - ke value = no or yes
    - no = no conservation of kinetic energy after atom swaps
    - yes = kinetic energy is conserved after atom swaps
17.86.2 Examples

| fix  | all mol/swap | 100 1 2 3 29494 300.0 ke no |
| fix  | mySwap fluid mol/swap | 500 10 1 2 482798 1.0 |

17.86.3 Description

This fix performs Monte Carlo swaps of two specified atom types within a randomly selected molecule. Two possible use cases are as follows.

First, consider a mixture of some molecules with atoms of itype and other molecules with atoms of jtype. The fix will select a random molecule and attempt to swap all the itype atoms to jtype for the first kind of molecule, or all the jtype atoms to itype for the second kind. Because the swap will only take place if it is energetically favorable, the fix can be used to determine the miscibility of 2 different kinds of molecules much more quickly than just dynamics would do it.

Second, consider diblock co-polymers with two types of monomers itype and jtype. The fix will select a random molecule and attempt to do a itype <--> jtype swap of all those monomers within the molecule. Thus the fix can be used to find the energetically favorable fractions of two flavors of diblock co-polymers.

Intra-molecular swaps of atom types are attempted every N timesteps. On that timestep, X swaps are attempted. For each attempt a single molecule ID is randomly selected. The range of possible molecule IDs from loID to hiID is pre-computed before each run begins. The loID/hiID is set for the molecule with the smallest/largest ID which has any itype or jtype atoms in it. Note that if you define a system with many molecule IDs between loID and hiID which have no itype or jtype atoms, then the fix will be inefficient at performing swaps. Also note that if atoms with molecule ID = 0 exist, they are not considered molecules by this fix; they are assumed to be solvent atoms or molecules.

Candidate atoms for swapping must also be in the fix group. Atoms within the selected molecule which are not itype or jtype are ignored.

When an atom is swapped from itype to jtype (or vice versa), if charges are defined, the charge values for itype versus jtype atoms are also swapped. This requires that all itype atoms in the system have the same charge value. Likewise all jtype atoms in the system must have the same charge value. If this is not the case, LAMMPS issues a warning that it cannot swap charge values.

If the ke keyword is set to yes, which is the default, and the masses of itype and jtype atoms are different, then when a swap occurs, the velocity of the swapped atom is rescaled by the sqrt of the mass ratio, so as to conserve the kinetic energy of the atom.

The potential energy of the entire system is computed before and after each swap is performed within a single molecule. The specified temperature T is used in the Metropolis criterion to accept or reject the attempted swap. If the swap is rejected all swapped values are reversed.

The potential energy calculations can include systems and models with the following features:

- manybody pair styles, including EAM
- hybrid pair styles
- long-range electrostatics (kspace)
- triclinic systems
- potential energy contributions from other fixes

For the last bullet point, fixes can have an associated potential energy. Examples of such fixes include: efield, gravity, addforce, langevin, restrain, temp/berendsen, temp/rescale, and wall fixes. For that energy to be included in the total potential energy of the system (the quantity used for the swap accept/reject decision), you MUST enable the fix_modify energy option for that fix. The doc pages for individual fix commands specify if this should be done.
Note: One comment on computational efficiency. If the cutoff lengths defined for the pair style are different for itype versus jtype atoms (for any of their interactions with any other atom type), then a new neighbor list needs to be generated for every attempted swap. This is potentially expensive if N is small or X is large.

17.86.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the fix to binary restart files. This includes information about the random number generator seed, the next timestep for MC exchanges, the number of exchange attempts and successes etc. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

Note: For this to work correctly, the timestep must not be changed after reading the restart with reset_timestep. The fix will try to detect it and stop with an error.

None of the fix_modify options are relevant to this fix.

This fix computes a global vector of length 2, which can be accessed by various output commands. The vector values are the following global cumulative quantities:

- 1 = swap attempts
- 2 = swap accepts

The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.86.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

17.86.6 Related commands

fix atom/swap, fix gcmc

17.86.7 Default

The option default is ke = yes.
17.87 fix momentum command

Accelerator Variants: momentum/kk

17.88 fix momentum/chunk command

17.88.1 Syntax

```
fix ID group-ID momentum N keyword values ...
```

- ID, group-ID are documented in fix command
- momentum = style name of this fix command
- N = adjust the momentum every this many timesteps one or more keyword/value pairs may be appended

```
fix ID group-ID momentum/chunk N chunkID keyword values ...
```

- ID, group-ID are documented in fix command
- momentum/chunk = style name of this fix command
- N = adjust the momentum per chunk every this many timesteps
- chunkID = ID of compute chunk/atom command
  one or more keyword/value settings may be appended to each of the fix commands:
- keyword = linear or angular or rescale
  linear values = xflag yflag zflag
  xflag,yflag,zflag = 0/1 to exclude/include each dimension
  angular values = none
  rescale values = none

17.88.2 Examples

```
fix 1 all momentum 1 linear 1 1 0
fix 1 all momentum 1 linear 1 1 1 rescale
fix 1 all momentum 100 linear 1 1 1 angular
fix 1 all momentum/chunk 100 molchunk linear 1 1 1 angular
```

17.88.3 Description

Fix momentum zeroes the linear and/or angular momentum of the group of atoms every N timesteps by adjusting the velocities of the atoms. Fix momentum/chunk works equivalently, but operates on a per-chunk basis.

One (or both) of the linear or angular keywords must be specified.

If the linear keyword is used, the linear momentum is zeroed by subtracting the center-of-mass velocity of the group or chunk from each atom. This does not change the relative velocity of any pair of atoms. One or more dimensions can be excluded from this operation by setting the corresponding flag to 0.
If the *angular* keyword is used, the angular momentum is zeroed by subtracting a rotational component from each atom.

This command can be used to insure the entire collection of atoms (or a subset of them) does not drift or rotate during the simulation due to random perturbations (e.g. *fix langevin* thermostating).

The *rescale* keyword enables conserving the kinetic energy of the group or chunk of atoms by rescaling the velocities after the momentum was removed.

Note that the *velocity* command can be used to create initial velocities with zero aggregate linear and/or angular momentum.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* command-line switch when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

### 17.88.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

### 17.88.5 Restrictions

Fix momentum/chunk is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 17.88.6 Related commands

*fix recenter, velocity*

### 17.88.7 Default

*none*
17.89 fix move command

17.89.1 Syntax

```
fix ID group-ID move style args keyword values ...
```

- ID, group-ID are documented in `fix` command
- move = style name of this fix command
- style = `linear` or `wiggle` or `rotate` or `transrot` or `variable`
  
  **linear**
  args = Vx Vy Vz
  Vx,Vy,Vz = components of velocity vector (velocity units), any component can be specified as NULL

  **wiggle**
  args = Ax Ay Az period
  Ax,Ay,Az = components of amplitude vector (distance units), any component can be specified as NULL
  period = period of oscillation (time units)

  **rotate**
  args = Px Py Pz Rx Ry Rz period
  Px,Py,Pz = origin point of axis of rotation (distance units)
  Rx,Ry,Rz = axis of rotation vector
  period = period of rotation (time units)

  **transrot**
  args = Vx Vy Vz Px Py Pz Rx Ry Rz period
  Vx,Vy,Vz = components of velocity vector (velocity units)
  Px,Py,Pz = origin point of axis of rotation (distance units)
  Rx,Ry,Rz = axis of rotation vector
  period = period of rotation (time units)

  **variable**
  args = v_dx v_dy v_dz v_vx vVy v_vz
  v_dx,v_dy,v_dz = 3 variable names that calculate x,y,z displacement as function of time, any component can be specified as NULL
  v_vx,v_vy,v_vz = 3 variable names that calculate x,y,z velocity as function of time, any component can be specified as NULL

- zero or more keyword/value pairs may be appended
- keyword = `units`
  
  units value = `box` or `lattice`

17.89.2 Examples

```
fix 1 boundary move wiggle 3.0 0.0 0.0 1.0 units box
fix 2 boundary move rotate 0.0 0.0 0.0 0.0 0.0 1.0 5.0
fix 2 boundary move variable v_myx v_myy NULL v_VX v_VY NULL
fix 3 boundary move transrot 0.1 0.1 0.0 0.0 0.0 0.0 0.0 0.0 1.0 5.0 units box
```
17.89.3 Description

Perform updates of position and velocity for atoms in the group each timestep using the specified settings or formulas, without regard to forces on the atoms. This can be useful for boundary or other atoms, whose movement can influence nearby atoms.

**Note:** The atoms affected by this fix should not normally be time integrated by other fixes (e.g. fix nve, fix nvt), since that will change their positions and velocities twice.

**Note:** As atoms move due to this fix, they will pass through periodic boundaries and be remapped to the other side of the simulation box, just as they would during normal time integration (e.g. via the fix nve command). It is up to you to decide whether periodic boundaries are appropriate with the kind of atom motion you are prescribing with this fix.

**Note:** As discussed below, atoms are moved relative to their initial position at the time the fix is specified. These initial coordinates are stored by the fix in “unwrapped” form, by using the image flags associated with each atom. See the `dump custom` command for a discussion of “unwrapped” coordinates. See the Atoms section of the `read_data` command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this fix by using the `set image` command.

The *linear* style moves atoms at a constant velocity, so that their position $X = (x,y,z)$ as a function of time is given in vector notation as

$$X(t) = X_0 + V \cdot \delta$$

where $X_0 = (x_0,y_0,z_0)$ is their position at the time the fix is specified, $V$ is the specified velocity vector with components $(V_x,V_y,V_z)$, and $\delta$ is the time elapsed since the fix was specified. This style also sets the velocity of each atom to $V = (V_x,V_y,V_z)$. If any of the velocity components is specified as NULL, then the position and velocity of that component is time integrated the same as the fix nve command would perform, using the corresponding force component on the atom.

Note that the *linear* style is identical to using the *variable* style with an *equal-style variable* that uses the `vdisplace()` function. E.g.

```
variable V equal 10.0
variable x equal vdisplace(0.0,$V$)
fix 1 boundary move variable v_x NULL NULL v_V NULL NULL
```

The *wiggle* style moves atoms in an oscillatory fashion, so that their position $X = (x,y,z)$ as a function of time is given in vector notation as

$$X(t) = X_0 + A \sin(\omega \cdot \delta)$$

where $X_0 = (x_0,y_0,z_0)$ is their position at the time the fix is specified, $A$ is the specified amplitude vector with components $(A_x,A_y,A_z)$, $\omega$ is $2\pi / \text{period}$, and $\delta$ is the time elapsed since the fix was specified. This style also sets the velocity of each atom to the time derivative of this expression. If any of the amplitude components is specified as NULL, then the position and velocity of that component is time integrated the same as the fix nve command would perform, using the corresponding force component on the atom.

Note that the *wiggle* style is identical to using the *variable* style with *equal-style variables* that use the `swiggle()` and `cwiggle()` functions. E.g.
variable A equal 10.0
variable T equal 5.0
variable omega equal 2.0*PI/$T
variable x equal swiggle(0.0,A,T)
variable v equal v_omega*(A-swiggle(0.0,A,T))
fix 1 boundary move variable v_x NULL NULL v_v NULL NULL

The rotate style rotates atoms around a rotation axis \( R = (R_x, R_y, R_z) \) that goes through a point \( P = (P_x, P_y, P_z) \). The period of the rotation is also specified. The direction of rotation for the atoms around the rotation axis is consistent with the right-hand rule: if your right-hand thumb points along \( R \), then your fingers wrap around the axis in the direction of rotation.

This style also sets the velocity of each atom to \( (\omega \times R_{\perp}) \) where \( \omega \) is its angular velocity around the rotation axis and \( R_{\perp} \) is a perpendicular vector from the rotation axis to the atom. If the defined atom_style assigns an angular velocity or angular momentum or orientation to each atom (atom styles sphere, ellipsoid, line, tri, body), then those properties are also updated appropriately to correspond to the atom’s motion and rotation over time.

The transrot style combines the effects of rotate and linear so that it is possible to prescribe a rotating group of atoms that also moves at a constant velocity. The arguments are for the translation first and then for the rotation. Since the rotation affects all coordinate components, it is not possible to set any of the translation vector components to NULL.

The variable style allows the position and velocity components of each atom to be set by formulas specified via the variable command. Each of the 6 variables is specified as an argument to the fix as v_name, where name is the variable name that is defined elsewhere in the input script.

Each variable must be of either the equal or atom style. Equal-style variables compute a single numeric quantity, that can be a function of the timestep as well as of other simulation values. Atom-style variables compute a numeric quantity for each atom, that can be a function per-atom quantities, such as the atom’s position, as well as of the timestep and other simulation values. Note that this fix stores the original coordinates of each atom (see note below) so that per-atom quantity can be used in an atom-style variable formula. See the variable command for details.

The first 3 variables (v_dx,v_dy,v_dz) specified for the variable style are used to calculate a displacement from the atom’s original position at the time the fix was specified. The second 3 variables (v_vx,v_vy,v_vz) specified are used to compute a velocity for each atom.

Any of the 6 variables can be specified as NULL. If both the displacement and velocity variables for a particular x,y,z component are specified as NULL, then the position and velocity of that component is time integrated the same as the fix nve command would perform, using the corresponding force component on the atom. If only the velocity variable for a component is specified as NULL, then the displacement variable will be used to set the position of the atom, and its velocity component will not be changed. If only the displacement variable for a component is specified as NULL, then the velocity variable will be used to set the velocity of the atom, and the position of the atom will be time integrated using that velocity.

The units keyword determines the meaning of the distance units used to define the linear velocity and wiggle amplitude and rotate origin. This setting is ignored for the variable style. A box value selects standard units as defined by the units command, e.g. velocity in Angstroms/fs and amplitude and position in Angstroms for units = real. A lattice value means the velocity units are in lattice spacings per time and the amplitude and position are in lattice spacings. The lattice command must have been previously used to define the lattice spacing. Each of these 3 quantities may be dependent on the x,y,z dimension, since the lattice spacings can be different in x,y,z.
17.89.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the original coordinates of moving atoms to binary restart files, as well as the initial timestep, so that the motion can be continuous in a restarted simulation. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

**Note:** Because the move positions are a function of the current timestep and the initial timestep, you cannot reset the timestep to a different value after reading a restart file, if you expect a fix move command to work in an uninterrupted fashion.

None of the fix_modify options are relevant to this fix.

This fix produces a per-atom array which can be accessed by various output commands. The number of columns for each atom is 3, and the columns store the original unwrapped x,y,z coords of each atom. The per-atom values can be accessed on any timestep.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

For rRESPA time integration, this fix adjusts the position and velocity of atoms on the outermost rRESPA level.

17.90 fix mscg command

17.90.1 Syntax

```plaintext
fix ID group-ID mscg N keyword args ...
```

- ID, group-ID are documented in fix command
- mscg = style name of this fix command
- N = envoke this fix every this many timesteps
- zero or more keyword/value pairs may be appended
- keyword = range or name or max
range arg = on or off
  on = range finding functionality is performed
  off = force matching functionality is performed
name args = name1 ... nameN
  name1,...,nameN = string names for each atom type (1-Ntype)
max args = maxb maxa maxd
  maxb,maxa,maxd = maximum bonds/angles/dihedrals per atom

17.90.2 Examples

```
fix 1 all mscg 1
fix 1 all mscg 1 range name A B
fix 1 all mscg 1 max 4 8 20
```

17.90.3 Description

This fix applies the Multi-Scale Coarse-Graining (MSCG) method to snapshots from a dump file to generate potentials for coarse-grained simulations from all-atom simulations, using a force-matching technique (Izvekov, Noid).

It makes use of the MS-CG library, written and maintained by Greg Voth’s group at the University of Chicago, which is freely available on their MS-CG GitHub site. See instructions on obtaining and installing the MS-CG library in the src/MS-CG/README file, which must be done before you build LAMMPS with this fix command and use the command in a LAMMPS input script.

An example script using this fix is provided the examples/mscg directory.

The general workflow for using LAMMPS in conjunction with the MS-CG library to create a coarse-grained model and run coarse-grained simulations is as follows:

1. Perform all-atom simulations on the system to be coarse grained.
2. Generate a trajectory mapped to the coarse-grained model.
3. Create input files for the MS-CG library.
4. Run the range finder functionality of the MS-CG library.
5. Run the force matching functionality of the MS-CG library.
6. Check the results of the force matching.
7. Run coarse-grained simulations using the new coarse-grained potentials.

This fix can perform the range finding and force matching steps 4 and 5 of the above workflow when used in conjunction with the `rerun` command. It does not perform steps 1-3 and 6-7.

Step 2 can be performed using a Python script (what is the name?) provided with the MS-CG library which defines the coarse-grained model and converts a standard LAMMPS dump file for an all-atom simulation (step 1) into a LAMMPS dump file which has the positions of and forces on the coarse-grained beads.

In step 3, an input file named “control.in” is needed by the MS-CG library which sets parameters for the range finding and force matching functionalities. See the examples/mscg/control.in file as an example. And see the documentation provided with the MS-CG library for more info on this file.

When this fix is used to perform steps 4 and 5, the MS-CG library also produces additional output files. The range finder functionality (step 4) outputs files defining pair and bonded interaction ranges. The force matching functionality (step 5) outputs tabulated force files for every interaction in the system. Other diagnostic files can also be output depending
on the parameters in the MS-CG library input script. Again, see the documentation provided with the MS-CG library for more info.

The `range` keyword specifies which MS-CG library functionality should be invoked. If `on`, the step 4 range finder functionality is invoked. `off`, the step 5 force matching functionality is invoked.

If the `name` keyword is used, string names are defined to associate with the integer atom types in LAMMPS. `Ntype` names must be provided, one for each atom type (1-Ntype).

The `max` keyword specifies the maximum number of bonds, angles, and dihedrals a bead can have in the coarse-grained model.

### 17.90.4 Restrictions

This fix is part of the MSCG package. It is only enabled if LAMMPS was built with that package. See the [Build package doc page](#) for more info.

The MS-CG library uses C++11, which may not be supported by older compilers. The MS-CG library also has some additional numeric library dependencies, which are described in its documentation.

Currently, the MS-CG library is not set up to run in parallel with MPI, so this fix can only be used in a serial LAMMPS build and run on a single processor.

### 17.90.5 Related commands

### 17.91 fix msst command

#### 17.91.1 Syntax

```
fix ID group-ID msst dir shockvel keyword value ...
```

- ID, group-ID are documented in `fix` command
- `msst` = style name of this fix
- `dir = x or y or z`
- `shockvel = shock velocity (strictly positive, distance/time units)`
- `zero or more keyword value pairs may be appended`
- `keyword = q or mu or p0 or v0 or e0 or tscale or beta or dfib`
LAMMPS Documentation, Release patch 23Jun2022

$q$ value = cell mass-like parameter (mass$^2$/distance$^4$ units)
$mu$ value = artificial viscosity (mass/length/time units)
$p0$ value = initial pressure in the shock equations (pressure units)
$v0$ value = initial simulation cell volume in the shock equations (distance$^3$ units)
$e0$ value = initial total energy (energy units)
tscale value = reduction in initial temperature (unitless fraction between 0.0 and 1.0)
$dftb$ value = yes or no for whether using MSST in conjunction with DFTB+
$beta$ value = scale factor for improved energy conservation

17.91.2 Examples

```plaintext

fix 2 all msst z 50.0 q 1.0e4 mu 1.0e4 v0 4.3419e+03 p0 3.7797e+03 e0 -9.72360e+02
tscale 0.01
fix 1 all msst y 100.0 q 1.0e5 mu 1.0e5 dftb yes beta 0.5
```

17.91.3 Description

This command performs the Multi-Scale Shock Technique (MSST) integration to update positions and velocities each timestep to mimic a compressive shock wave passing over the system. See (Reed) for a detailed description of this method. The MSST varies the cell volume and temperature in such a way as to restrain the system to the shock Hugoniot and the Rayleigh line. These restraints correspond to the macroscopic conservation laws dictated by a shock front. shockvel determines the steady shock velocity that will be simulated.

To perform a simulation, choose a value of $q$ that provides volume compression on the timescale of 100 fs to 1 ps. If the volume is not compressing, either the shock speed is chosen to be below the material sound speed or $p0$ has been chosen inaccurately. Volume compression at the start can be sped up by using a non-zero value of tscale. Use the smallest value of tscale that results in compression.

Under some special high-symmetry conditions, the pressure (volume) and/or temperature of the system may oscillate for many cycles even with an appropriate choice of mass-like parameter $q$. Such oscillations have physical significance in some cases. The optional $mu$ keyword adds an artificial viscosity that helps break the system symmetry to equilibrate to the shock Hugoniot and Rayleigh line more rapidly in such cases.

The keyword tscale is a factor between 0 and 1 that determines what fraction of thermal kinetic energy is converted to compressive strain kinetic energy at the start of the simulation. Setting this parameter to a non-zero value may assist in compression at the start of simulations where it is slow to occur.

If keywords $e0$, $p0$, or $v0$ are not supplied, these quantities will be calculated on the first step, after the energy specified by tscale is removed. The value of $e0$ is not used in the dynamical equations, but is used in calculating the deviation from the Hugoniot.

The keyword beta is a scaling term that can be added to the MSST ionic equations of motion to account for drift in the conserved quantity during long timescale simulations, similar to a Berendsen thermostat. See (Reed) and (Goldman) for more details. The value of beta must be between 0.0 and 1.0 inclusive. A value of 0.0 means no contribution, a value of 1.0 means a full contribution.

Values of shockvel less than a critical value determined by the material response will not have compressive solutions. This will be reflected in lack of significant change of the volume in the MSST.

For all pressure styles, the simulation box stays orthogonal in shape. Parrinello-Rahman boundary conditions (tilted box) are supported by LAMMPS, but are not implemented for MSST.

This fix computes a temperature and pressure and potential energy each timestep. To do this, the fix creates its own computes of style “temp” “pressure”, and “pe”, as if these commands had been issued:
compute fix-ID_MSST_temp all temp
calculate fix-ID_MSST_press all pressure fix-ID_MSST_temp
calculate fix-ID_MSST_pe all pe

See the compute temp and compute pressure commands for details. Note that the IDs of the new computes are the fix-ID + "_MSST_temp" or "MSST_press" or "_MSST_pe". The group for the new computes is “all”.

The dftb keyword is to allow this fix to be used when LAMMPS is being driven by DFTB+, a density-functional tight-binding code. If the keyword dftb is used with a value of yes, then the MSST equations are altered to account for the electron entropy contribution to the Hugonio relations and total energy. See (Reed2) and (Goldman) for details on this contribution. In this case, you must define a fix external command in your input script, which is used to callback to DFTB+ during the LAMMPS timestepping. DFTB+ will communicate its info to LAMMPS via that fix.

17.91.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of all internal variables to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The cumulative energy change in the system imposed by this fix is included in the thermodynamic output keywords ecouple and econserve. See the thermo_style doc page for details.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

The progress of the MSST can be monitored by printing the global scalar and global vector quantities computed by the fix.

As mentioned above, the scalar is the cumulative energy change due to the fix. By monitoring the thermodynamic econserve output, this can be used to test if the MD timestep is sufficiently small for accurate integration of the dynamic equations.

The global vector contains four values in the following order. The vector values output by this fix are “intensive”.

[duhugoniot, drayleigh, lagrangian_speed, lagrangian_position]
1. duhugoniot is the departure from the Hugoniot (temperature units).
2. drayleigh is the departure from the Rayleigh line (pressure units).
3. lagrangian_speed is the laboratory-frame Lagrangian speed (particle velocity) of the computational cell (velocity units).
4. lagrangian_position is the computational cell position in the reference frame moving at the shock speed. This is usually a good estimate of distance of the computational cell behind the shock front.

To print these quantities to the log file with descriptive column headers, the following LAMMPS commands are suggested:

fix msst all msst z
variable dhug equal f_msst[1]
variable dray equal f_msst[2]
variable lgr_vel equal f_msst[3]

(continues on next page)
variable lgr_pos equal f_msst[4]
thermo_style custom step temp ke pe lz pzz econserve v_dhug v_dray v_lgr_vel v_lgr_pos f_msst

17.91.5 Restrictions

This fix style is part of the SHOCK package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

All cell dimensions must be periodic. This fix can not be used with a triclinic cell. The MSST fix has been tested only for the group-ID all.

17.91.6 Related commands

fix nphug, fix deform

17.91.7 Default

The keyword defaults are q = 10, mu = 0, tscale = 0.01, dftb = no, beta = 0.0. Note that p0, v0, and e0 are calculated on the first timestep.

17.92 fix mvv/dpd command

17.93 fix mvv/edpd command

17.94 fix mvv/tdpd command

17.94.1 Syntax

fix ID group-ID mvv/dpd lambda
fix ID group-ID mvv/edpd lambda
fix ID group-ID mvv/tdpd lambda

• ID, group-ID are documented in fix command
• mvv/dpd, mvv/edpd, mvv/tdpd = style name of this fix command
• lambda = (optional) relaxation parameter (unitless)
17.94.2 Examples

```plaintext
fix 1 all mvv/dpd
fix 1 all mvv/dpd 0.5
fix 1 all mvv/edpd
fix 1 all mvv/edpd 0.5
fix 1 all mvv/tdpd
fix 1 all mvv/tdpd 0.5
```

17.94.3 Description

Perform time integration using the modified velocity-Verlet (MVV) algorithm to update position and velocity (fix mvv/dpd), or position, velocity and temperature (fix mvv/edpd), or position, velocity and concentration (fix mvv/tdpd) for particles in the group each timestep.

The modified velocity-Verlet (MVV) algorithm aims to improve the stability of the time integrator by using an extrapolated version of the velocity for the force evaluation:

\[
v(t + \frac{\Delta t}{2}) = v(t) + \frac{\Delta t}{2} \cdot a(t)
\]

\[
r(t + \Delta t) = r(t) + \Delta t \cdot v(t + \frac{\Delta t}{2})
\]

\[
a(t + \Delta t) = \frac{1}{m} \cdot F[r(t + \Delta t), v(t) + \lambda \cdot \Delta t \cdot a(t)]
\]

\[
v(t + \Delta t) = v(t + \frac{\Delta t}{2}) + \frac{\Delta t}{2} \cdot a(t + \Delta t)
\]

where the parameter \( \lambda \) depends on the specific choice of DPD parameters, and needs to be tuned on a case-by-case basis. Specification of a \textit{lambda} value is optional. If specified, the setting must be from 0.0 to 1.0. If not specified, a default value of 0.5 is used, which effectively reproduces the standard velocity-Verlet (VV) scheme. For more details, see \textit{Groot}.

Fix \textit{mvv/dpd} updates the position and velocity of each atom. It can be used with the \textit{pair_style mdpd} command or other pair styles such as \textit{pair dpd}.

Fix \textit{mvv/edpd} updates the per-atom temperature, in addition to position and velocity, and must be used with the \textit{pair_style edpd} command.

Fix \textit{mvv/tdpd} updates the per-atom chemical concentration, in addition to position and velocity, and must be used with the \textit{pair_style tdpd} command.

17.94.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to \textit{binary restart files}. None of the \textit{fix_modify} options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various \textit{output commands}. No parameter of this fix can be used with the \textit{start/stop} keywords of the \textit{run} command. This fix is not invoked during \textit{energy minimization}.  

17.94. fix mvv/tdpd command 1351
17.94.5 Restrictions

This fix is part of the DPD-MESO package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

fix 2 all neb 1.0 perp 1.0 end first 1.0 end last 1.0
fix 1 all neb 1.0 parallel ideal end last/efirst 1
```

17.95.3 Description

Add nudging forces to atoms in the group for a multi-replica simulation run via the `neb` command to perform a nudged elastic band (NEB) calculation for finding the transition state. Hi-level explanations of NEB are given with the `neb` command and on the `How to replica` doc page. The `fix neb` command must be used with the “neb” command and defines how inter-replica nudging forces are computed. A NEB calculation is divided into two stages. In the first stage n replicas are relaxed toward a MEP until convergence. In the second stage, the climbing image scheme (see (Henkelman2)) is enabled, so that the replica having the highest energy relaxes toward the saddle point (i.e. the point of highest energy along the MEP), and a second relaxation is performed.

A key purpose of the nudging forces is to keep the replicas equally spaced. During the NEB calculation, the 3N-length vector of interatomic force $F_i = -\nabla V$ for each replica $I$ is altered. For all intermediate replicas (i.e. for $1 < I < N$, except the climbing replica) the force vector becomes:

$$F_i = -\nabla V + (\nabla V \cdot T') T' + F_{\text{nudge parallel}} + F_{\text{nudge perp}}$$

$T'$ is the unit “tangent” vector for replica I and is a function of $R_i$, $R_{i-1}$, $R_{i+1}$, and the potential energy of the 3 replicas; it points roughly in the direction of $(R_{i+1} - R_i)$; see the (Henkelman1) paper for details. $R_i$ are the atomic coordinates of replica I; $R_{i-1}$ and $R_{i+1}$ are the coordinates of its neighbor replicas. The term $(\nabla V \cdot T')$ is used to remove the component of the gradient parallel to the path which would tend to distribute the replica unevenly along the path. $F_{\text{nudge parallel}}$ is an artificial nudging force which is applied only in the tangent direction and which maintains the equal spacing between replicas (see below for more information). $F_{\text{nudge perp}}$ is an optional artificial spring which is applied in a direction perpendicular to the tangent direction and which prevent the paths from forming acute kinks (see below for more information).

In the second stage of the NEB calculation, the interatomic force $F_i$ for the climbing replica (the replica of highest energy after the first stage) is changed to:

$$F_i = -\nabla V + 2 (\nabla V \cdot T') T' + F_{\text{nudge perp}}$$

and the relaxation procedure is continued to a new converged MEP.

The keyword `parallel` specifies how the parallel nudging force is computed. With a value of `neigh`, the parallel nudging force is computed as in (Henkelman1) by connecting each intermediate replica with the previous and the next image:

$$F_{\text{nudge parallel}} = K_{\text{spring}} \times (|R_{i+1} - R_i| - |R_i - R_{i-1}|)$$

Note that in this case the specified $K_{\text{spring}}$ is in force/distance units.

With a value of `ideal`, the spring force is computed as suggested in ref (WeinanE) <WeinanE>:

$$F_{\text{nudge parallel}} = -K_{\text{spring}} \times (R_{\text{Dideal}} - R_{\text{D}}) / (2 \times \text{meanDist})$$

where $R_{\text{D}}$ is the “reaction coordinate” see `neb` section, and $R_{\text{Dideal}}$ is the ideal $R_{\text{D}}$ for which all the images are equally spaced. I.e. $R_{\text{Dideal}} = (I-1)^{\text{meanDist}}$ when the climbing replica is off, where $I$ is the replica number). The meanDist is the average distance between replicas. Note that in this case the specified $K_{\text{spring}}$ is in force units.

Note that the `ideal` form of nudging can often be more effective at keeping the replicas equally spaced.
The keyword *perp* specifies if and how a perpendicular nudging force is computed. It adds a spring force perpendicular to the path in order to prevent the path from becoming too strongly kinked. It can significantly improve the convergence of the NEB calculation when the resolution is poor. I.e. when few replicas are used; see *Maras* for details.

The perpendicular spring force is given by

\[ F_{\text{nudge\_perp}} = K_{\text{spring2}} \cdot F(R_{i-1},R_i,R_{i+1}) (R_{i+1} + R_{i-1} - 2 R_i) \]

where \( K_{\text{spring2}} \) is the specified value. \( F(R_{i-1} R_i R_{i+1}) \) is a smooth scalar function of the angle \( R_{i-1} R_i R_{i+1} \). It is equal to 0.0 when the path is straight and is equal to 1 when the angle \( R_{i-1} R_i R_{i+1} \) is acute. \( F(R_{i-1} R_i R_{i+1}) \) is defined in *Jonsson*.

If \( K_{\text{spring2}} \) is set to 0.0 (the default) then no perpendicular spring force is added.

By default, no additional forces act on the first and last replicas during the NEB relaxation, so these replicas simply relax toward their respective local minima. By using the key word *end*, additional forces can be applied to the first and/or last replicas, to enable them to relax toward a MEP while constraining their energy \( E \) to the target energy \( E_{\text{Target}} \).

If \( E_{\text{Target}} > E \), the interatomic force \( F_i \) for the specified replica becomes:

\[
F_i = -\nabla V + (\nabla V \cdot T') + (E - E_{\text{Target}}) \cdot K_{\text{spring3}} \cdot T', \quad \text{when } \nabla V \cdot T' < 0
\]
\[
F_i = -\nabla V + (\nabla V \cdot T') + (E_{\text{Target}} - E) \cdot K_{\text{spring3}} \cdot T', \quad \text{when } \nabla V \cdot T' > 0
\]

The “spring” constant on the difference in energies is the specified \( K_{\text{spring3}} \) value.

When *estyle* is specified as *first*, the force is applied to the first replica. When *estyle* is specified as *last*, the force is applied to the last replica. Note that the *end* keyword can be used twice to add forces to both the first and last replicas.

For both these *estyle* settings, the target energy \( E_{\text{Target}} \) is set to the initial energy of the replica (at the start of the NEB calculation).

If the *estyle* is specified as last/efirst or last/efirst/middle, force is applied to the last replica, but the target energy \( E_{\text{Target}} \) is continuously set to the energy of the first replica, as it evolves during the NEB relaxation.

The difference between these two *estyle* options is as follows. When *estyle* is specified as last/efirst, no change is made to the inter-replica force applied to the intermediate replicas (neither first or last). If the initial path is too far from the MEP, an intermediate replica may relax “faster” and reach a lower energy than the last replica. In this case the intermediate replica will be relaxing toward its own local minima. This behavior can be prevented by specifying *estyle* as last/efirst/middle which will alter the inter-replica force applied to intermediate replicas by removing the contribution of the gradient to the inter-replica force. This will only be done if a particular intermediate replica has a lower energy than the first replica. This should effectively prevent the intermediate replicas from over-relaxing.

After converging a NEB calculation using an *estyle* of last/efirst/middle, you should check that all intermediate replicas have a larger energy than the first replica. If this is not the case, the path is probably not a MEP.

Finally, note that the last replica may never reach the target energy if it is stuck in a local minima which has a larger energy than the target energy.
17.95.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, as invoked by the minimize command via the neb command.

17.95.5 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the Build package doc page for more info.

17.95.6 Related commands

neb

17.95.7 Default

The option defaults are parallel = neigh, perp = 0.0, ends is not specified (no inter-replica force on the end replicas).

17.96 fix neb/spin command

17.96.1 Syntax

fix ID group-ID neb/spin Kspring

- ID, group-ID are documented in fix command
- neb/spin = style name of this fix command

Kspring = spring constant for parallel nudging force
(force/distance units or force units, see parallel keyword)
17.96.2 Examples

```
fix 1 active neb/spin 1.0
```

17.96.3 Description

Add nudging forces to spins in the group for a multi-replica simulation run via the `neb/spin` command to perform a geodesic nudged elastic band (GNEB) calculation for finding the transition state. Hi-level explanations of GNEB are given with the `neb/spin` command and on the Howto replica doc page. The fix neb/spin command must be used with the “neb/spin” command and defines how inter-replica nudging forces are computed. A GNEB calculation is divided into two stages. In the first stage n replicas are relaxed toward a MEP until convergence. In the second stage, the climbing image scheme is enabled, so that the replica having the highest energy relaxes toward the saddle point (i.e. the point of highest energy along the MEP), and a second relaxation is performed.

The nudging forces are calculated as explained in (BessarabB). See this reference for more explanation about their expression.

17.96.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, as invoked by the minimize command via the neb/spin command.

17.96.5 Restrictions

This command can only be used if LAMMPS was built with the SPIN package. See the Build package doc page for more info.

17.99.3 Description

These commands perform time integration on Nose-Hoover style non-Hamiltonian equations of motion which are designed to generate positions and velocities sampled from the canonical (nvt), isothermal-isobaric (npt), and isenthalpic (nph) ensembles. This updates the position and velocity for atoms in the group each timestep.

The thermostatting and barostatting is achieved by adding some dynamic variables which are coupled to the particle velocities (thermostatting) and simulation domain dimensions (barostatting). In addition to basic thermostatting and barostatting, these fixes can also create a chain of thermostats coupled to the particle thermostat, and another chain of thermostats coupled to the barostat variables. The barostat can be coupled to the overall box volume, or to individual dimensions, including the xy, xz and yz tilt dimensions. The external pressure of the barostat can be specified as either a scalar pressure (isobaric ensemble) or as components of a symmetric stress tensor (constant stress ensemble). When used correctly, the time-averaged temperature and stress tensor of the particles will match the target values specified by Tstart/Tstop and Pstart/Pstop.

The equations of motion used are those of Shinoda et al in (Shinoda), which combine the hydrostatic equations of Martyna, Tobias and Klein in (Martyna) with the strain energy proposed by Parrinello and Rahman in (Parrinello). The time integration schemes closely follow the time-reversible measure-preserving Verlet and rRESPA integrators derived by Tuckerman et al in (Tuckerman).

The thermostat parameters for fix styles nvt and npt are specified using the temp keyword. Other thermostat-related keywords are tchain, tloop and drag, which are discussed below.

The thermostat is applied to only the translational degrees of freedom for the particles. The translational degrees of freedom can also have a bias velocity removed before thermostatting takes place; see the description below. The desired temperature at each timestep is a ramped value during the run from Tstart to Tstop. The Tdamp parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 10.0 means to relax the temperature in a timespan of (roughly) 10 time units (e.g. $\tau$ or fs or ps - see the units command). The atoms in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the integration.
Note: A Nose-Hoover thermostat will not work well for arbitrary values of Tdamp. If Tdamp is too small, the temperature can fluctuate wildly; if it is too large, the temperature will take a very long time to equilibrate. A good choice for many models is a Tdamp of around 100 timesteps. Note that this is NOT the same as 100 time units for most units settings. A simple way to ensure this, is via using an immediate variable expression accessing the thermo property 'dt', which is the length of the time step. Example:

```
fix 1 all nvt temp 300.0 300.0 $(100.0*dt)
```

The barostat parameters for fix styles npt and nph is specified using one or more of the iso, aniso, tri, x, y, z, xy, xz, yz, and couple keywords. These keywords give you the ability to specify all 6 components of an external stress tensor, and to couple various of these components together so that the dimensions they represent are varied together during a constant-pressure simulation.

Other barostat-related keywords are pchain, mtk, ploop, nreset, drag, and dilate, which are discussed below.

Orthogonal simulation boxes have 3 adjustable dimensions (x,y,z). Triclinic (non-orthogonal) simulation boxes have 6 adjustable dimensions (x,y,z,xy,xz,yz). The create_box, read data, and read_restart commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the xy,xz,yz tilt factors.

The target pressures for each of the 6 components of the stress tensor can be specified independently via the x, y, z, xy, xz, yz keywords, which correspond to the 6 simulation box dimensions. For each component, the external pressure or tensor component at each timestep is a ramped value during the run from Pstart to Pstop. If a target pressure is specified for a component, then the corresponding box dimension will change during a simulation. For example, if the y keyword is used, the y-box length will change. If the xy keyword is used, the xy tilt factor will change. A box dimension will not change if that component is not specified, although you have the option to change that dimension via the fix deform command.

Note that in order to use the xy, xz, or yz keywords, the simulation box must be triclinic, even if its initial tilt factors are 0.0.

For all barostat keywords, the Pdamp parameter operates like the Tdamp parameter, determining the time scale on which pressure is relaxed. For example, a value of 10.0 means to relax the pressure in a timespan of (roughly) 10 time units (e.g. τ or fs or ps - see the units command).

Note: A Nose-Hoover barostat will not work well for arbitrary values of Pdamp. If Pdamp is too small, the pressure and volume can fluctuate wildly; if it is too large, the pressure will take a very long time to equilibrate. A good choice for many models is a Pdamp of around 1000 timesteps. However, note that Pdamp is specified in time units, and that timesteps are NOT the same as time units for most units settings.

The relaxation rate of the barostat is set by its inertia W:

\[ W = (N + 1)kT_{\text{target}}P_{\text{damp}}^2 \]

where \( N \) is the number of atoms, \( k \) is the Boltzmann constant, and \( T_{\text{target}} \) is the target temperature of the barostat (Martyna). If a thermostat is defined, \( T_{\text{target}} \) is the target temperature of the thermostat. If a thermostat is not defined, \( T_{\text{target}} \) is set to the current temperature of the system when the barostat is initialized. If this temperature is too low the simulation will quit with an error. Note: in previous versions of LAMMPS, \( T_{\text{target}} \) would default to a value of 1.0 for lj units and 300.0 otherwise if the system had a temperature of exactly zero.

If a thermostat is not specified by this fix, \( T_{\text{target}} \) can be manually specified using the Ptemp parameter. This may be useful if the barostat is initialized when the current temperature does not reflect the steady state temperature of the system. This keyword may also be useful in athermal simulations where the temperature is not well defined.
Regardless of what atoms are in the fix group (the only atoms which are time integrated), a global pressure or stress tensor is computed for all atoms. Similarly, when the size of the simulation box is changed, all atoms are re-scaled to new positions, unless the keyword \textit{dilate} is specified with a \textit{dilate-group-ID} for a group that represents a subset of the atoms. This can be useful, for example, to leave the coordinates of atoms in a solid substrate unchanged and controlling the pressure of a surrounding fluid. This option should be used with care, since it can be unphysical to dilate some atoms and not others, because it can introduce large, instantaneous displacements between a pair of atoms (one dilated, one not) that are far from the dilation origin. Also note that for atoms not in the fix group, a separate time integration fix like \texttt{fix nve} or \texttt{fix nvt} can be used on them, independent of whether they are dilated or not.

The \textit{couple} keyword allows two or three of the diagonal components of the pressure tensor to be “coupled” together. The value specified with the keyword determines which are coupled. For example, \textit{xz} means the \( P_{xx} \) and \( P_{zz} \) components of the stress tensor are coupled. \textit{Yxz} means all 3 diagonal components are coupled. Coupling means two things: the instantaneous stress will be computed as an average of the corresponding diagonal components, and the coupled box dimensions will be changed together in lockstep, meaning coupled dimensions will be dilated or contracted by the same percentage every timestep. The \( P_{start} \), \( P_{stop} \), \( P_{damp} \) parameters for any coupled dimensions must be identical. \textit{Couple xyz} can be used for a 2d simulation; the \( z \) dimension is simply ignored.

The \textit{iso}, \textit{aniso}, and \textit{tri} keywords are simply shortcuts that are equivalent to specifying several other keywords together. The keyword \textit{iso} means couple all 3 diagonal components together when pressure is computed (hydrostatic pressure), and dilate/contract the dimensions together. Using “\textit{iso Pstart Pstop Pdamp}” is the same as specifying these 4 keywords:

\begin{verbatim}
x Pstart Pstop Pdamp
y Pstart Pstop Pdamp
z Pstart Pstop Pdamp
couple xyz
\end{verbatim}

The keyword \textit{aniso} means \( x \), \( y \), and \( z \) dimensions are controlled independently using the \( P_{xx} \), \( P_{yy} \), and \( P_{zz} \) components of the stress tensor as the driving forces, and the specified scalar external pressure. Using “\textit{aniso Pstart Pstop Pdamp}” is the same as specifying these 4 keywords:

\begin{verbatim}
x Pstart Pstop Pdamp
y Pstart Pstop Pdamp
z Pstart Pstop Pdamp
couple none
\end{verbatim}

The keyword \textit{tri} means \( x \), \( y \), \( z \), \( xy \), \( xz \), and \( yz \) dimensions are controlled independently using their individual stress components as the driving forces, and the specified scalar pressure as the external normal stress. Using “\textit{tri Pstart Pstop Pdamp}” is the same as specifying these 7 keywords:

\begin{verbatim}
x Pstart Pstop Pdamp
y Pstart Pstop Pdamp
z Pstart Pstop Pdamp
xy 0.0 0.0 Pdamp
yz 0.0 0.0 Pdamp
xz 0.0 0.0 Pdamp
couple none
\end{verbatim}

In some cases (e.g. for solids) the pressure (volume) and/or temperature of the system can oscillate undesirably when a Nose/Hoover barostat and thermostat is applied. The optional \textit{drag} keyword will damp these oscillations, although it alters the Nose/Hoover equations. A value of 0.0 (no drag) leaves the Nose/Hoover formalism unchanged. A non-zero value adds a drag term; the larger the value specified, the greater the damping effect. Performing a short run and
monitoring the pressure and temperature is the best way to determine if the drag term is working. Typically a value between 0.2 to 2.0 is sufficient to damp oscillations after a few periods. Note that use of the drag keyword will interfere with energy conservation and will also change the distribution of positions and velocities so that they do not correspond to the nominal NVT, NPT, or NPH ensembles.

An alternative way to control initial oscillations is to use chain thermostats. The keyword tchain determines the number of thermostats in the particle thermostat. A value of 1 corresponds to the original Nose-Hoover thermostat. The keyword pchain specifies the number of thermostats in the chain thermostatting the barostat degrees of freedom. A value of 0 corresponds to no thermostatting of the barostat variables.

The mtk keyword controls whether or not the correction terms due to Martyna, Tuckerman, and Klein are included in the equations of motion (Martyna). Specifying no reproduces the original Hoover barostat, whose volume probability distribution function differs from the true NPT and NPH ensembles by a factor of 1/V. Hence using yes is more correct, but in many cases the difference is negligible.

The keyword tloop can be used to improve the accuracy of integration scheme at little extra cost. The initial and final updates of the thermostat variables are broken up into tloop sub-steps, each of length dt/tloop. This corresponds to using a first-order Suzuki-Yoshida scheme (Tuckerman). The keyword ploop does the same thing for the barostat thermostat.

The keyword nreset controls how often the reference dimensions used to define the strain energy are reset. If this keyword is not used, or is given a value of zero, then the reference dimensions are set to those of the initial simulation domain and are never changed. If the simulation domain changes significantly during the simulation, then the final average pressure tensor will differ significantly from the specified values of the external stress tensor. A value of nstep means that every nstep timesteps, the reference dimensions are set to those of the current simulation domain.

The scaleyz, scalexz, and scalexy keywords control whether or not the corresponding tilt factors are scaled with the associated box dimensions when barostatting triclinic periodic cells. The default values yes will turn on scaling, which corresponds to adjusting the linear dimensions of the cell while preserving its shape. Choosing no ensures that the tilt factors are not scaled with the box dimensions. See below for restrictions and default values in different situations. In older versions of LAMMPS, scaling of tilt factors was not performed. The old behavior can be recovered by setting all three scale keywords to no.

The flip keyword allows the tilt factors for a triclinic box to exceed half the distance of the parallel box length, as discussed below. If the flip value is set to yes, the bound is enforced by flipping the box when it is exceeded. If the flip value is set to no, the tilt will continue to change without flipping. Note that if applied stress induces large deformations (e.g. in a liquid), this means the box shape can tilt dramatically and LAMMPS will run less efficiently, due to the large volume of communication needed to acquire ghost atoms around a processor’s irregular-shaped sub-domain. For extreme values of tilt, LAMMPS may also lose atoms and generate an error.

The fixedpoint keyword specifies the fixed point for barostat volume changes. By default, it is the center of the box. Whatever point is chosen will not move during the simulation. For example, if the lower periodic boundaries pass through (0,0,0), and this point is provided to fixedpoint, then the lower periodic boundaries will remain at (0,0,0), while the upper periodic boundaries will move twice as far. In all cases, the particle trajectories are unaffected by the chosen value, except for a time-dependent constant translation of positions.

If the update keyword is used with the dipole value, then the orientation of the dipole moment of each particle is also updated during the time integration. This option should be used for models where a dipole moment is assigned to finite-size particles, e.g. spheroids via use of the atom_style hybrid sphere dipole command.

The default dipole orientation integrator can be changed to the Dullweber-Leimkuhler-McLachlan integration scheme (Dullweber) when using update with the value dipole/dlm. This integrator is symplectic and time-reversible, giving better energy conservation and allows slightly longer timesteps at only a small additional computational cost.

Note: Using a barostat coupled to tilt dimensions xy, xz, yz can sometimes result in arbitrarily large values of the tilt dimensions, i.e. a dramatically deformed simulation box. LAMMPS allows the tilt factors to grow a small amount
beyond the normal limit of half the box length (0.6 times the box length), and then performs a box “flip” to an equivalent periodic cell. See the discussion of the flip keyword above, to allow this bound to be exceeded, if desired.

The flip operation is described in more detail in the page for fix deform. Both the barostat dynamics and the atom trajectories are unaffected by this operation. However, if a tilt factor is incremented by a large amount (1.5 times the box length) on a single timestep, LAMMPS can not accommodate this event and will terminate the simulation with an error. This error typically indicates that there is something badly wrong with how the simulation was constructed, such as specifying values of \( P_{\text{start}} \) that are too far from the current stress value, or specifying a timestep that is too large. Triclinic barostatting should be used with care. This also is true for other barostat styles, although they tend to be more forgiving of insults. In particular, it is important to recognize that equilibrium liquids can not support a shear stress and that equilibrium solids can not support shear stresses that exceed the yield stress.

One exception to this rule is if the first dimension in the tilt factor (x for xy) is non-periodic. In that case, the limits on the tilt factor are not enforced, since flipping the box in that dimension does not change the atom positions due to non-periodicity. In this mode, if you tilt the system to extreme angles, the simulation will simply become inefficient due to the highly skewed simulation box.

Note: Unlike the fix temp/berendsen command which performs thermostatting but NO time integration, these fixes perform thermostatting/barostatting AND time integration. Thus you should not use any other time integration fix, such as fix nve on atoms to which this fix is applied. Likewise, fix nvt and fix npt should not normally be used on atoms that also have their temperature controlled by another fix - e.g. by fix langevin or fix temp/rescale commands.

See the Howto thermostat and Howto barostat doc pages for a discussion of different ways to compute temperature and perform thermostatting and barostatting.

These fixes compute a temperature and pressure each timestep. To do this, the thermostat and barostat fixes create their own computes of style “temp” and “pressure”, as if one of these sets of commands had been issued:

For fix nvt:

```plaintext
compute fix-ID_temp group-ID temp
```

For fix npt and fix nph:

```plaintext
compute fix-ID_temp all temp
compute fix-ID_press all pressure fix-ID_temp
```

For fix nvt, the group for the new temperature compute is the same as the fix group. For fix npt and fix nph, the group for both the new temperature and pressure compute is “all” since pressure is computed for the entire system. In the case of fix nph, the temperature compute is not used for thermostatting, but just for a kinetic-energy contribution to the pressure. See the compute temp and compute pressure commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix_ID + underscore + “press”.

Note that these are NOT the computes used by thermodynamic output (see the thermo_style command) with ID = thermo_temp and thermo_press. This means you can change the attributes of these fix’s temperature or pressure via the compute_modify command. Or you can print this temperature or pressure during thermodynamic output via the thermo_style custom command using the appropriate compute-ID. It also means that changing attributes of thermo_temp or thermo_press will have no effect on this fix.

Like other fixes that perform thermostatting, this fix can be used with compute commands that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial region, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the fix_modify command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual compute temp commands to determine which ones include
a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

These fixes can be used with either the verlet or respa integrators. When using one of the barostat fixes with respa, LAMMPS uses an integrator constructed according to the following factorization of the Liouville propagator (for two rRESPA levels):

\[ \exp(iL\Delta t) = \hat{E} \exp\left(iL_{T_{\text{baro}}} \frac{\Delta t}{2}\right) \exp\left(iL_{T_{\text{part}}} \frac{\Delta t}{2}\right) \exp\left(iL_{T_{\epsilon,2}} \frac{\Delta t}{2}\right) \exp\left(iL_{T_{\epsilon,1}} \frac{\Delta t}{2}\right) \exp\left(iL_{T_{\epsilon,1}} \frac{\Delta t}{2}\right) \exp\left(iL_{T_{\epsilon,0}} \frac{\Delta t}{2}\right) \]

\[ \times \left[ \exp\left(iL_{2}^{(1)} \frac{\Delta t}{2n}\right) \exp\left(iL_{2}^{(0)} \frac{\Delta t}{2n}\right) \exp\left(iL_{2}^{(1)} \frac{\Delta t}{2n}\right) \exp\left(iL_{2}^{(0)} \frac{\Delta t}{2n}\right) \right]^{n} \]

\[ \times \exp\left(iL_{2}^{(2)} \frac{\Delta t}{2}\right) \exp\left(iL_{2}^{(2)} \frac{\Delta t}{2}\right) \exp\left(iL_{T_{\text{baro}}} \frac{\Delta t}{2}\right) + \mathcal{O}(\Delta t^3) \]

This factorization differs somewhat from that of Tuckerman et al, in that the barostat is only updated at the outermost rRESPA level, whereas Tuckerman’s factorization requires splitting the pressure into pieces corresponding to the forces computed at each rRESPA level. In theory, the latter method will exhibit better numerical stability. In practice, because Pdamp is normally chosen to be a large multiple of the outermost rRESPA timestep, the barostat dynamics are not the limiting factor for numerical stability. Both factorizations are time-reversible and can be shown to preserve the phase space measure of the underlying non-Hamiltonian equations of motion.

**Note:** This implementation has been shown to conserve linear momentum up to machine precision under NVT dynamics. Under NPT dynamics, for a system with zero initial total linear momentum, the total momentum fluctuates close to zero. It may occasionally undergo brief excursions to non-negligible values, before returning close to zero. Over long simulations, this has the effect of causing the center-of-mass to undergo a slow random walk. This can be mitigated by resetting the momentum at infrequent intervals using the fix momentum command.

The fix npt and fix nph commands can be used with rigid bodies or mixtures of rigid bodies and non-rigid particles (e.g. solvent). But there are also fix rigid/npt and fix rigid/nph commands, which are typically a more natural choice. See the page for those commands for more discussion of the various ways to do this.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
17.99.4 Restart, fix_modify, output, run start/stop, minimize info

These fixes write the state of all the thermostat and barostat variables to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify temp and press options are supported by these fixes. You can use them to assign a compute you have defined to this fix which will be used in its thermostatting or barostatting procedure, as described above. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

Note: If both the temp and press keywords are used in a single thermo_modify command (or in two separate commands), then the order in which the keywords are specified is important. Note that a pressure compute defines its own temperature compute as an argument when it is specified. The temp keyword will override this (for the pressure compute being used by fix npt), but only if the temp keyword comes after the press keyword. If the temp keyword comes before the press keyword, then the new pressure compute specified by the press keyword will be unaffected by the temp setting.

The cumulative energy change in the system imposed by these fixes, via either thermostatting and/or barostatting, is included in the thermodynamic output keywords ecouple and econserve. See the thermo_style page for details.

These fixes compute a global scalar which can be accessed by various output commands. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

These fixes compute also compute a global vector of quantities, which can be accessed by various output commands. The vector values are “intensive”.

The vector stores internal Nose/Hoover thermostat and barostat variables. The number and meaning of the vector values depends on which fix is used and the settings for keywords tchain and pchain, which specify the number of Nose/Hoover chains for the thermostat and barostat. If no thermostatting is done, then tchain is 0. If no barostatting is done, then pchain is 0. In the following list, “ndof” is 0, 1, 3, or 6, and is the number of degrees of freedom in the barostat. Its value is 0 if no barostat is used, else its value is 6 if any off-diagonal stress tensor component is barostatted, else its value is 1 if couple xyz is used or couple xy for a 2d simulation, otherwise its value is 3.

The order of values in the global vector and their meaning is as follows. The notation means there are tchain values for eta, followed by tchain for eta_dot, followed by ndof for omega, etc:

- $\eta_{[\text{tchain}]}$ = particle thermostat displacements (unitless)
- $\dot{\eta}_{[\text{tchain}]}$ = particle thermostat velocities (1/time units)
- $\omega_{[\text{ndof}]}$ = barostat displacements (unitless)
- $\dot{\omega}_{[\text{ndof}]}$ = barostat velocities (1/time units)
- $\eta_{p[\text{pchain}]}$ = barostat thermostat displacements (unitless)
- $\dot{\eta}_{p[\text{pchain}]}$ = barostat thermostat velocities (1/time units)
- $\text{PE}_{\eta_{[\text{tchain}]} \text{dot}[\text{tchain}]}$ = potential energy of each particle thermostat displacement (energy units)
- $\text{KE}_{\eta_{[\text{tchain}]} \text{dot}[\text{tchain}]}$ = kinetic energy of each particle thermostat velocity (energy units)
- $\text{PE}_{\omega_{[\text{ndof}]} \text{dot}[\text{ndof}]}$ = potential energy of each barostat displacement (energy units)
- $\text{KE}_{\omega_{[\text{ndof}]} \text{dot}[\text{ndof}]}$ = kinetic energy of each barostat velocity (energy units)
- $\text{PE}_{\eta_{p[\text{pchain}]} \text{dot}[\text{pchain}]}$ = potential energy of each barostat thermostat displacement (energy units)
- $\text{KE}_{\eta_{p[\text{pchain}]} \text{dot}[\text{pchain}]}$ = kinetic energy of each barostat thermostat velocity (energy units)
These fixes can ramp their external temperature and pressure over multiple runs, using the \textit{start} and \textit{stop} keywords of the \texttt{run} command. See the \texttt{run} command for details of how to do this.

These fixes are not invoked during \textit{energy minimization}.

\section*{17.99.5 Restrictions}

\(X, y, z\) cannot be barostatted if the associated dimension is not periodic. \(Xy, xz,\) and \(yz\) can only be barostatted if the simulation domain is triclinic and the second dimension in the keyword (\(y\) dimension in \(xy\)) is periodic. \(Z, xz,\) and \(yz,\) cannot be barostatted for 2D simulations. The \texttt{create\_box}, \texttt{read\_data}, and \texttt{read\_restart} commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the \(xy, xz, yz\) tilt factors.

For the \textit{temp} keyword, the final \(T_{stop}\) cannot be 0.0 since it would make the external \(T = 0.0\) at some timestep during the simulation which is not allowed in the Nose/Hoover formulation.

The $scaleyz\ yes$ and $scalexz\ yes$ keyword/value pairs cannot be used for 2D simulations. $scaleyz\ yes$, $scalexz\ yes$, and $scalexy\ yes$ options can only be used if the second dimension in the keyword is periodic, and if the tilt factor is not coupled to the barostat via keywords $tri$, $yz$, $xz$, and $xy$

These fixes can be used with dynamic groups as defined by the \texttt{group} command. Likewise they can be used with groups to which atoms are added or deleted over time, e.g. a deposition simulation. However, the conservation properties of the thermostat and barostat are defined for systems with a static set of atoms. You may observe odd behavior if the atoms in a group vary dramatically over time or the atom count becomes very small.

```
17.102.3 Description

These commands perform time integration on Nose-Hoover style non-Hamiltonian equations of motion for nuclei and electrons in the group for the electron force field model. The fixes are designed to generate positions and velocities sampled from the canonical (nvt), isothermal-isobaric (npt), and isenthalpic (nph) ensembles. This is achieved by adding some dynamic variables which are coupled to the particle velocities (thermostatting) and simulation domain dimensions (barostatting). In addition to basic thermostatting and barostatting, these fixes can also create a chain of thermostats coupled to the particle thermostat, and another chain of thermostats coupled to the barostat variables. The barostat can be coupled to the overall box volume, or to individual dimensions, including the xy, xz and yz tilt dimensions. The external pressure of the barostat can be specified as either a scalar pressure (isobaric ensemble) or as components of a symmetric stress tensor (constant stress ensemble). When used correctly, the time-averaged temperature and stress tensor of the particles will match the target values specified by Tstart/Tstop and Pstart/Pstop.

The operation of these fixes is exactly like that described by the fix nvt, npt, and nph commands, except that the radius and radial velocity of electrons are also updated. Likewise the temperature and pressure calculated by the fix, using the computes it creates (as discussed in the fix nvt, npt, and nph doc page), are performed with computes that include the eFF contribution to the temperature or kinetic energy from the electron radial velocity.

**Note:** there are two different pressures that can be reported for eFF when defining the pair_style (see pair eff/cut to understand these settings), one (default) that considers electrons do not contribute radial virial components (i.e. electrons treated as incompressible ‘rigid’ spheres) and one that does. The radial electronic contributions to the virials are only tallied if the flexible pressure option is set, and this will affect both global and per-atom quantities. In principle, the true pressure of a system is somewhere in between the rigid and the flexible eFF pressures, but, for most cases, the difference between these two pressures will not be significant over long-term averaged runs (i.e. even though the energy partitioning changes, the total energy remains similar).

**Note:** currently, there is no available option for the user to set or create temperature distributions that include the radial electronic degrees of freedom with the velocity command, so the user must allow for these degrees of freedom to equilibrate (i.e. equi-partitioning of energy) through time integration.

17.102.4 Restart, fix_modify, output, run start/stop, minimize info

See the page for the fix nvt, npt, and nph commands for details.

17.102.5 Restrictions

This fix is part of the EFF package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

Other restriction discussed on the page for the fix nvt, npt, and nph commands also apply.

**Note:** The temperature for systems (regions or groups) with only electrons and no nuclei is 0.0 (i.e. not defined) in the current temperature calculations, a practical example would be a uniform electron gas or a very hot plasma, where electrons remain delocalized from the nuclei. This is because, even though electron virials are included in the temperature calculation, these are averaged over the nuclear degrees of freedom only. In such cases a corrective term must be added to the pressure to get the correct kinetic contribution.

```

## 17.104.3 Description

This fix can be used to simulate non-equilibrium molecular dynamics (NEMD) under diagonal flow fields, including uniaxial and bi-axial flow. Simulations under continuous extensional flow may be carried out for an indefinite amount of time. It is an implementation of the boundary conditions from (Dobson), and also uses numerical lattice reduction as was proposed by (Hunt). The lattice reduction algorithm is from (Semaev). The fix is intended for simulations of homogeneous flows, and integrates the SLLOD equations of motion, originally proposed by Hoover and Ladd (see (Evans and Morriss)). Additional detail about this implementation can be found in (Nicholson and Rutledge).

Note that NEMD simulations of a continuously strained system can be performed using the `fix deform`, `fix nvt/sllod`, and `compute temp/deform` commands.

The applied flow field is set by the `eps` keyword. The values $\dot{e}_{xx}$ and $\dot{e}_{yy}$ correspond to the strain rates in the $xx$ and $yy$ directions. It is implicitly assumed that the flow field is traceless, and therefore the strain rate in the $zz$ direction is equal to $-(\dot{e}_{xx} + \dot{e}_{yy})$.

---

**Note:** Due to an instability in the SLLOD equations under extension, `fix momentum` should be used to regularly reset the linear momentum.

The boundary conditions require a simulation box that does not have a consistent alignment relative to the applied flow field. Since LAMMPS utilizes an upper-triangular simulation box, it is not possible to express the evolving simulation box in the same coordinate system as the flow field. This fix keeps track of two coordinate systems: the flow frame, and the upper triangular LAMMPS frame. The coordinate systems are related to each other through the QR decomposition, as is illustrated in the image below.

![Diagram of coordinate systems](image.png)
During most molecular dynamics operations, the system is represented in the LAMMPS frame. Only when the positions and velocities are updated is the system rotated to the flow frame, and it is rotated back to the LAMMPS frame immediately afterwards. For this reason, all vector-valued quantities (except for the tensors from \texttt{compute pressure/uef} and \texttt{compute temp/uef}) will be computed in the LAMMPS frame. Rotationally invariant scalar quantities like the temperature and hydrostatic pressure are frame-invariant and will be computed correctly. Additionally, the system is in the LAMMPS frame during all of the output steps, and therefore trajectory files made using the \texttt{dump} command will be in the LAMMPS frame unless the \texttt{dump cfg/uef} command is used.

Temperature control is achieved with the default Nose-Hoover style thermostat documented in \texttt{fix npt}. When this fix is active, only the peculiar velocity of each atom is stored, defined as the velocity relative to the streaming velocity. This is in contrast to \texttt{fix nvt/sllod}, which uses a lab-frame velocity, and removes the contribution from the streaming velocity in order to compute the temperature.

Pressure control is achieved using the default Nose-Hoover barostat documented in \texttt{fix npt}. There are two ways to control the pressure using this fix. The first method involves using the \texttt{ext} keyword along with the \texttt{iso} pressure style. With this method, the pressure is controlled by scaling the simulation box isotropically to achieve the average pressure only in the directions specified by \texttt{ext}. For example, if the \texttt{ext} value is set to \texttt{xy}, the average pressure \((P_{xx}+P_{yy})/2\) will be controlled.

This example command will control the total hydrostatic pressure under uniaxial tension:

\begin{verbatim}
fix f1 all npt/uef temp 0.7 0.7 0.5 iso 1 1 5 erate -0.5 -0.5 ext xyz
\end{verbatim}

This example command will control the average stress in compression directions, which would typically correspond to free surfaces under drawing with uniaxial tension:

\begin{verbatim}
fix f2 all npt/uef temp 0.7 0.7 0.5 iso 1 1 5 erate -0.5 -0.5 ext xy
\end{verbatim}

The second method for pressure control involves setting the normal stresses using the \texttt{x}, \texttt{y}, and/or \texttt{z} keywords. When using this method, the same pressure must be specified via \texttt{Pstart} and \texttt{Pstop} for all dimensions controlled. Any choice of pressure conditions that would cause LAMMPS to compute a deviatoric stress are not permissible and will result in an error. Additionally, all dimensions with controlled stress must have the same applied strain rate. The \texttt{ext} keyword must be set to the default value (\texttt{xyz}) when using this method.

For example, the following commands will work:

\begin{verbatim}
fix f3 all npt/uef temp 0.7 0.7 0.5 x 1 1 5 y 1 1 5 erate -0.5 -0.5
fix f4 all npt/uef temp 0.7 0.7 0.5 z 1 1 5 erate 0.5 0.5
\end{verbatim}

The following commands will not work:

\begin{verbatim}
fix f5 all npt/uef temp 0.7 0.7 0.5 x 1 1 5 z 1 1 5 erate -0.5 -0.5
fix f6 all npt/uef temp 0.7 0.7 0.5 x 1 1 5 z 2 2 5 erate 0.5 0.5
\end{verbatim}

These fix computes a temperature and pressure each timestep. To do this, it creates its own computes of style “temp/uef” and “pressure/uef”, as if one of these two sets of commands had been issued:

\begin{verbatim}
compute fix-ID_temp group-ID temp/uef
compute fix-ID_press group-ID pressure/uef fix-ID_temp
compute fix-ID_temp all temp/uef
compute fix-ID_press all pressure/uef fix-ID_temp
\end{verbatim}

See the \texttt{compute temp/uef} and \texttt{compute pressure/uef} commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix_ID + underscore + “press”.

---

1370 Chapter 17. Fixes
17.104.4 Restart, fix_modify, output, run start/stop, minimize info

The fix writes the state of all the thermostat and barostat variables, as well as the cumulative strain applied, to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

**Note:** It is not necessary to set the strain keyword when resuming a run from a restart file. Only for resuming from data files, which do not contain the cumulative applied strain, will this keyword be necessary.

This fix can be used with the fix_modify temp and press options. The temperature and pressure computes used must be of type temp/uef and pressure/uef.

This fix computes the same global scalar and vector quantities as fix npt.

The fix is not invoked during energy minimization.

17.104.5 Restrictions

This fix is part of the UEF package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

Due to requirements of the boundary conditions, when the strain keyword is set to zero (or unset), the initial simulation box must be cubic and have style triclinic. If the box is initially of type ortho, use change_box before invoking the fix.

**Note:** When resuming from restart files, you may need to use box tilt large since lammps has internal criteria from lattice reduction that are not the same as the criteria in the numerical lattice reduction algorithm.

17.104.6 Related commands

fix nvt, fix nvt/sllod, compute temp/uef, compute pressure/uef, dump cfg/uef

17.104.7 Default

The default keyword values specific to this fix are exy = xyz, strain = 0 0. The remaining defaults are the same as for fix npt except tchain = 1. The reason for this change is given in fix nvt/sllod.

17.105 fix nph/asphere command

Accelerator Variants: nph/asphere/omp

17.105.1 Syntax

```
fix ID group-ID nph/asphere args keyword value ...
```

- ID, group-ID are documented in fix command
- nph/asphere = style name of this fix command
- additional barostat related keyword/value pairs from the fix nph command can be appended

17.105.2 Examples

```
fix 1 all nph/asphere iso 0.0 0.0 1000.0
fix 2 all nph/asphere x 5.0 5.0 1000.0
fix 2 all nph/asphere x 5.0 5.0 1000.0 drag 0.2
fix 2 water nph/asphere aniso 0.0 0.0 1000.0 dilate partial
```

17.105.3 Description

Perform constant NPH integration to update position, velocity, orientation, and angular velocity each timestep for aspherical or ellipsoidal particles in the group using a Nose/Hoover pressure barostat. P is pressure; H is enthalpy. This creates a system trajectory consistent with the isenthalpic ensemble.

This fix differs from the fix nph command, which assumes point particles and only updates their position and velocity. Additional parameters affecting the barostat are specified by keywords and values documented with the fix nph command. See, for example, discussion of the aniso, and dilate keywords.

The particles in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the NPH integration.

Regardless of what particles are in the fix group, a global pressure is computed for all particles. Similarly, when the size of the simulation box is changed, all particles are re-scaled to new positions, unless the keyword dilate is specified with a value of partial, in which case only the particles in the fix group are re-scaled. The latter can be useful for leaving the coordinates of particles in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

This fix computes a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp/asphere” and “pressure”, as if these commands had been issued:

```
compute fix-ID_temp all temp/asphere
compute fix-ID_press all pressure fix-ID_temp
```

See the compute temp/asphere and compute pressure commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix_ID + underscore + “press”, and the group for the new computes is “all” since pressure is computed for the entire system.

Note that these are NOT the computes used by thermodynamic output (see the thermo_style command) with ID = thermo_temp and thermo_pressure. This means you can change the attributes of this fix’s temperature or pressure via the
compute_modify command or print this temperature or pressure during thermodynamic output via the thermo_style custom command using the appropriate compute-ID. It also means that changing attributes of thermo_temp or thermo_press will have no effect on this fix.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 17.105.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover barostat to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify temp and press options are supported by this fix. You can use them to assign a compute you have defined to this fix which will be used in its thermostating or barostating procedure. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

The cumulative energy change in the system imposed by this fix is included in the thermodynamic output keywords ecouple and econserve. See the thermo_style doc page for details.

This fix computes the same global scalar and global vector of quantities as does the fix nph command.

This fix can ramp its target pressure over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

### 17.105.5 Restrictions

This fix is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This fix requires that atoms store torque and angular momentum and a quaternion as defined by the atom_style ellipsoid command.

All particles in the group must be finite-size. They cannot be point particles, but they can be aspherical or spherical as defined by their shape attribute.
17.105.6 Related commands

fix 2 water nph/body aniso 0.0 0.0 1000.0 dilate partial
```

17.106.3 Description

Perform constant NPH integration to update position, velocity, orientation, and angular velocity each timestep for body particles in the group using a Nose/Hoover pressure barostat. P is pressure; H is enthalpy. This creates a system trajectory consistent with the isenthalpic ensemble.

This fix differs from the `fix nph` command, which assumes point particles and only updates their position and velocity.

Additional parameters affecting the barostat are specified by keywords and values documented with the `fix nph` command. See, for example, discussion of the `aniso` and `dilate` keywords.

The particles in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the NPH integration.

Regardless of what particles are in the fix group, a global pressure is computed for all particles. Similarly, when the size of the simulation box is changed, all particles are re-scaled to new positions, unless the keyword `dilate` is specified with a value of `partial`, in which case only the particles in the fix group are re-scaled. The latter can be useful for leaving the coordinates of particles in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

This fix computes a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp/body” and “pressure”, as if these commands had been issued:
compute fix-ID_temp all temp/body
compute fix-ID_press all pressure fix-ID_temp

See the compute temp/body and compute pressure commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix_ID + underscore + “press”, and the group for the new computes is “all” since pressure is computed for the entire system.

Note that these are NOT the computes used by thermodynamic output (see the thermo_style command) with ID = thermo_temp and thermo_press. This means you can change the attributes of this fix’s temperature or pressure via the compute_modify command or print this temperature or pressure during thermodynamic output via the thermo_style custom command using the appropriate compute-ID. It also means that changing attributes of thermo_temp or thermo_press will have no effect on this fix.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

17.106.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover barostat to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify temp and press options are supported by this fix. You can use them to assign a compute you have defined to this fix which will be used in its thermostating or barostating procedure. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

The cumulative energy change in the system imposed by this fix is included in the thermodynamic output keywords ecouple and econserve. See the thermo_style doc page for details.

This fix computes the same global scalar and global vector of quantities as does the fix nph command.

This fix can ramp its target pressure over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.
17.106.5 Restrictions

This fix is part of the BODY package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This fix requires that atoms store torque and angular momentum and a quaternion as defined by the atom_style body command.

17.106.6 Related commands

fix nph, fix nve_body, fix nvt_body, fix npt_body, fix_modify

17.106.7 Default

none

17.107 fix nph/sphere command

Accelerator Variants: nph/sphere/omp

17.107.1 Syntax

fix ID group-ID nph/sphere args keyword value ...

- ID, group-ID are documented in fix command
- nph/sphere = style name of this fix command
- keyword = disc
  - disc value = none = treat particles as 2d discs, not spheres
- additional barostat related keyword/value pairs from the fix nph command can be appended

17.107.2 Examples

```
fix 1 all nph/sphere iso 0.0 0.0 1000.0
fix 2 all nph/sphere x 5.0 5.0 1000.0
disc
fix 2 all nph/sphere x 5.0 5.0 1000.0 disc
fix 2 all nph/sphere x 5.0 5.0 1000.0 drag 0.2
fix 2 water nph/sphere aniso 0.0 0.0 1000.0 dilate partial
```
17.107.3 Description

Perform constant NPH integration to update position, velocity, and angular velocity each timestep for finite-size spherical particles in the group using a Nose/Hoover pressure barostat. P is pressure; H is enthalpy. This creates a system trajectory consistent with the isenthalpic ensemble.

This fix differs from the fix nph command, which assumes point particles and only updates their position and velocity.

If the disc keyword is used, then each particle is treated as a 2d disc (circle) instead of as a sphere. This is only possible for 2d simulations, as defined by the dimension keyword. The only difference between discs and spheres in this context is their moment of inertia, as used in the time integration.

Additional parameters affecting the barostat are specified by keywords and values documented with the fix nph command. See, for example, discussion of the aniso, and dilate keywords.

The particles in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the NPH integration.

Regardless of what particles are in the fix group, a global pressure is computed for all particles. Similarly, when the size of the simulation box is changed, all particles are re-scaled to new positions, unless the keyword dilate is specified with a value of partial, in which case only the particles in the fix group are re-scaled. The latter can be useful for leaving the coordinates of particles in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

This fix computes a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp/sphere” and “pressure”, as if these commands had been issued:

```
compute fix-ID_temp all temp/sphere
compute fix-ID_press all pressure fix-ID_temp
```

See the compute temp/sphere and compute pressure commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix_ID + underscore + “press”, and the group for the new computes is “all” since pressure is computed for the entire system.

Note that these are NOT the computes used by thermodynamic output (see the thermo_style command) with ID = thermo_temp and thermo_press. This means you can change the attributes of this fix’s temperature or pressure via the compute_modify command or print this temperature or pressure during thermodynamic output via the thermo_style custom command using the appropriate compute-ID. It also means that changing attributes of thermo_temp or thermo_press will have no effect on this fix.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
17.107.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover barostat to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify temp and press options are supported by this fix. You can use them to assign a compute you have defined to this fix which will be used in its thermostating or barostating procedure. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

The cumulative energy change in the system imposed by this fix is included in the thermodynamic output keywords ecouple and econserve. See the thermo_style doc page for details.

This fix computes the same global scalar and global vector of quantities as does the fix nph command.

This fix can ramp its target pressure over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

17.107.5 Restrictions

This fix requires that atoms store torque and angular velocity (omega) and a radius as defined by the atom_style sphere command.

All particles in the group must be finite-size spheres. They cannot be point particles.

Use of the disc keyword is only allowed for 2d simulations, as defined by the dimension keyword.

17.108.2 Examples

fix myhug all nphug temp 1.0 1.0 10.0 z 40.0 40.0 70.0
fix myhug all nphug temp 1.0 1.0 10.0 iso 40.0 40.0 70.0 drag 200.0 tchain 1 pchain 0

17.108.3 Description

This command is a variant of the Nose-Hoover fix npt fix style. It performs time integration of the Hugoniostat equations of motion developed by Ravelo et al. (Ravelo). These equations compress the system to a state with average axial stress or pressure equal to the specified target value and that satisfies the Rankine-Hugoniot (RH) jump conditions for steady shocks.

The compression can be performed either hydrostatically (using keyword iso, aniso, or tri) or uniaxially (using keywords x, y, or z). In the hydrostatic case, the cell dimensions change dynamically so that the average axial stress in all three directions converges towards the specified target value. In the uniaxial case, the chosen cell dimension changes dynamically so that the average axial stress in that direction converges towards the target value. The other two cell dimensions are kept fixed (zero lateral strain).

This leads to the following additional restrictions on the keywords:

- One and only one of the following keywords should be used: iso, aniso, tri, x, y, z
- The specified initial and final target pressures must be the same.
- The keywords xy, xz, yz may not be used.
- The only admissible value for the couple keyword is xyz, which has the same effect as keyword iso
- The temp keyword must be used to specify the time constant for kinetic energy relaxation, but initial and final target temperature values are ignored.
Essentially, a Hugoniostat simulation is an NPT simulation in which the user-specified target temperature is replaced with a time-dependent target temperature $T_t$ obtained from the following equation:

$$T_t - T = \frac{\frac{1}{2} (P + P_0) (V_0 - V) + E_0 - E}{N_{dof} k_B} = \Delta$$

where $T$ and $T_t$ are the instantaneous and target temperatures, $P$ and $P_0$ are the instantaneous and reference pressures or axial stresses, depending on whether hydrostatic or uniaxial compression is being performed, $V$ and $V_0$ are the instantaneous and reference volumes, $E$ and $E_0$ are the instantaneous and reference internal energy (potential plus kinetic), $N_{dof}$ is the number of degrees of freedom used in the definition of temperature, and $k_B$ is the Boltzmann constant. $\Delta$ is the negative deviation of the instantaneous temperature from the target temperature. When the system reaches a stable equilibrium, the value of $\Delta$ should fluctuate about zero.

The values of $E_0$, $V_0$, and $P_0$ are the instantaneous values at the start of the simulation. These can be overridden using the fix_modify keywords $e0$, $v0$, and $p0$ described below.

---

**Note:** Unlike the `fix temp/berendsen` command which performs thermostatting but NO time integration, this fix performs thermostatting/barostatting AND time integration. Thus you should not use any other time integration fix, such as `fix nve` on atoms to which this fix is applied. Likewise, this fix should not be used on atoms that have their temperature controlled by another fix - e.g. by `fix langevin` or `fix temp/rescale` commands.

---

This fix computes a temperature and pressure at each timestep. To do this, the fix creates its own computes of style “temp” and “pressure”, as if one of these two sets of commands had been issued:

```plaintext
compute fix-ID_temp group-ID temp
compute fix-ID_press group-ID pressure fix-ID_temp
compute fix-ID_temp all temp
compute fix-ID_press all pressure fix-ID_temp
```

See the `compute temp` and `compute pressure` commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix_ID + underscore + “press”. The group for the new computes is “all” since pressure is computed for the entire system.

Note that these are NOT the computes used by thermodynamic output (see the `thermo_style` command) with ID = `thermo_temp` and `thermo_press`. This means you can change the attributes of this fix’s temperature or pressure via the `compute_modify` command or print this temperature or pressure during thermodynamic output via the `thermo_style custom` command using the appropriate compute-ID. It also means that changing attributes of `thermo_temp` or `thermo_press` will have no effect on this fix.

---

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
17.108.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the values of $E_0$, $V_0$, and $P_0$, as well as the state of all the thermostat and barostat variables to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify e0, v0 and p0 keywords can be used to define the values of $E_0$, $V_0$, and $P_0$. Note the the values for $e0$ and $v0$ are extensive, and so must correspond to the total energy and volume of the entire system, not energy and volume per atom. If any of these quantities are not specified, then the instantaneous value in the system at the start of the simulation is used.

The fix_modify temp and press options are supported by this fix. You can use them to assign a compute you have defined to this fix which will be used in its thermostating or barostatting procedure, as described above. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

The cumulative energy change in the system imposed by this fix is included in the thermodynamic output keywords ecouple and econserve. See the thermo_style doc page for details. Note that this energy is *not* included in the definition of internal energy $E$ when calculating the value of Delta in the above equation.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

This fix also computes a global vector of quantities, which can be accessed by various output commands. The scalar The vector values are “intensive”.

The vector stores three quantities unique to this fix ($\Delta$, $Us$, and $up$), followed by all the internal Nose/Hoover thermostat and barostat variables defined for fix npt. Delta is the deviation of the temperature from the target temperature, given by the above equation. $Us$ and $up$ are the shock and particle velocity corresponding to a steady shock calculated from the RH conditions. They have units of distance/time.

17.108.5 Restrictions

This fix style is part of the SHOCK package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

All the usual restrictions for fix npt apply, plus the additional ones mentioned above.

17.108.6 Related commands

fix msst, fix npt, fix_modify

fix 2 water npt/asphere temp 300.0 300.0 100.0 aniso 0.0 0.0 1000.0 dilate partial
```

### 17.109.3 Description

Perform constant NPT integration to update position, velocity, orientation, and angular velocity each timestep for aspherical or ellipsoidal particles in the group using a Nose/Hoover temperature thermostat and Nose/Hoover pressure barostat. P is pressure; T is temperature. This creates a system trajectory consistent with the isothermal-isobaric ensemble.

This fix differs from the `fix npt` command, which assumes point particles and only updates their position and velocity.

The thermostat is applied to both the translational and rotational degrees of freedom for the aspherical particles, assuming a compute is used which calculates a temperature that includes the rotational degrees of freedom (see below). The translational degrees of freedom can also have a bias velocity removed from them before thermostatting takes place; see the description below.

Additional parameters affecting the thermostat and barostat are specified by keywords and values documented with the `fix npt` command. See, for example, discussion of the `temp`, `iso`, `aniso`, and `dilate` keywords.

The particles in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the NPT integration.

Regardless of what particles are in the fix group, a global pressure is computed for all particles. Similarly, when the size of the simulation box is changed, all particles are re-scaled to new positions, unless the keyword `dilate` is specified with a value of `partial`, in which case only the particles in the fix group are re-scaled. The latter can be useful for leaving the coordinates of particles in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

This fix computes a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp/asphere” and “pressure”, as if these commands had been issued:

```
compute fix-ID_temp all temp/asphere
compute fix-ID_press all pressure fix-ID_temp
```
See the `compute temp/asphere` and `compute pressure` commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix_ID + underscore + “press”, and the group for the new computes is “all” since pressure is computed for the entire system.

Note that these are NOT the computes used by thermodynamic output (see the `thermo_style` command) with ID = `thermo_temp` and `thermo_press`. This means you can change the attributes of this fix’s temperature or pressure via the `compute_modify` command or print this temperature or pressure during thermodynamic output via the `thermo_style custom` command using the appropriate compute-ID. It also means that changing attributes of `thermo_temp` or `thermo_press` will have no effect on this fix.

Like other fixes that perform thermostatting, this fix can be used with compute commands that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial region, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the `fix_modify` command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual `compute temp commands` to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 17.109.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat and barostat to binary restart files. See the `read_restart` command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The `fix_modify temp` and `press` options are supported by this fix. You can use them to assign a `compute` you have defined to this fix which will be used in its thermostatting or barostatting procedure. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

The cumulative energy change in the system imposed by this fix is included in the thermodynamic output keywords `ecouple` and `econserve`. See the thermo_style doc page for details.

This fix computes the same global scalar and global vector of quantities as does the `fix npt` command.

This fix can ramp its target temperature and pressure over multiple runs, using the `start` and `stop` keywords of the `run` command. See the `run` command for details of how to do this.

This fix is not invoked during energy minimization.
17.109.5 Restrictions

This fix is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This fix requires that atoms store torque and angular momentum and a quaternion as defined by the atom_style ellipsoid command.

All particles in the group must be finite-size. They cannot be point particles, but they can be aspherical or spherical as defined by their shape attribute.

fix 2 water npt/body temp 300.0 300.0 100.0 aniso 0.0 0.0 1000.0 dilate partial
```

17.110.3 Description

Perform constant NPT integration to update position, velocity, orientation, and angular velocity each timestep for body particles in the group using a Nose/Hoover temperature thermostat and Nose/Hoover pressure barostat. P is pressure; T is temperature. This creates a system trajectory consistent with the isothermal-isobaric ensemble.

This fix differs from the fix npt command, which assumes point particles and only updates their position and velocity.

The thermostat is applied to both the translational and rotational degrees of freedom for the body particles, assuming a compute is used which calculates a temperature that includes the rotational degrees of freedom (see below). The translational degrees of freedom can also have a bias velocity removed from them before thermostating takes place; see the description below.
Additional parameters affecting the thermostat and barostat are specified by keywords and values documented with the *fix npt* command. See, for example, discussion of the *temp*, *iso*, *aniso*, and *dilate* keywords.

The particles in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the NPT integration.

Regardless of what particles are in the fix group, a global pressure is computed for all particles. Similarly, when the size of the simulation box is changed, all particles are re-scaled to new positions, unless the keyword *dilate* is specified with a value of *partial*, in which case only the particles in the fix group are re-scaled. The latter can be useful for leaving the coordinates of particles in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

This fix computes a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp/body” and “pressure”, as if these commands had been issued:

```plaintext
compute fix-ID_temp all temp/body
compute fix-ID_press all pressure fix-ID_temp
```

See the *compute temp/body* and *compute pressure* commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix_ID + underscore + “press”, and the group for the new computes is “all” since pressure is computed for the entire system.

Note that these are NOT the computes used by thermodynamic output (see the *thermo_style* command) with ID = *thermo_temp* and *thermo_press*. This means you can change the attributes of this fix’s temperature or pressure via the *compute_modify* command or print this temperature or pressure during thermodynamic output via the *thermo_style custom* command using the appropriate compute-ID. It also means that changing attributes of *thermo_temp* or *thermo_press* will have no effect on this fix.

Like other fixes that perform thermostatting, this fix can be used with *compute commands* that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial region, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the *fix_modify* command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual *compute temp commands* to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.
17.110.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat and barostat to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify temp and press options are supported by this fix. You can use them to assign a compute you have defined to this fix which will be used in its thermostating or barostating procedure. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

The cumulative energy change in the system imposed by this fix is included in the thermodynamic output keywords ecouple and econserve. See the thermo_style doc page for details.

This fix computes the same global scalar and global vector of quantities as does the fix npt command.

This fix can ramp its target temperature and pressure over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

17.110.5 Restrictions

This fix is part of the BODY package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This fix requires that atoms store torque and angular momentum and a quaternion as defined by the atom_style body command.

17.111 fix npt/cauchy command

17.111.1 Syntax

fix ID group-ID style_name keyword value ...

- ID, group-ID are documented in fix command
- style_name = npt/cauchy
- one or more keyword/value pairs may be appended
- keyword = temp or iso or aniso or tri or x or y or z or xy or yz or xz or couple or tchain or pchain or mtk or tloop or ploop or nreset or drag or dilate or scalexy or scaleyz or scalexz or flip or fixedpoint
temp values = Tstart Tstop Tdamp
    Tstart, Tstop = external temperature at start/end of run
    Tdamp = temperature damping parameter (time units)
iso or aniso or tri values = Pstart Pstop Pdamp
    Pstart, Pstop = scalar external pressure at start/end of run (pressure units)
    Pdamp = pressure damping parameter (time units)
x or y or z or xy or yz or xz values = Pstart Pstop Pdamp
    Pstart, Pstop = external stress tensor component at start/end of run (pressure units)
couple = none or xyz or xy or yz or xz
   耦 = external stress tensor component at start/end of run (pressure units)
tchain value = N
    N = length of thermostat chain (1 = single thermostat)
pchain values = N
    N length of thermostat chain on barostat (0 = no thermostat)
mrk value = yes or no
    = add in MTK adjustment term or not
    α = strength of Cauchy stress control parameter
continue value = yes or no
    = whether of not to continue from a previous run
fixedpoint values = x y z
    = perform barostat dilation/contraction around this point (distance units)

17.111.2 Examples

fix 1 water npt/cauchy temp 300.0 300.0 100.0 iso 0.0 0.0 1000.0 alpha 0.001

17.111.3 Description

This command performs time integration on Nose-Hoover style non-Hamiltonian equations of motion which are designed to generate positions and velocities sampled from the isothermal-isobaric (npt) ensembles. This updates the position and velocity for atoms in the group each timestep and the box dimensions.

The thermostating and barostating is achieved by adding some dynamic variables which are coupled to the particle velocities (thermostating) and simulation domain dimensions (barostating). In addition to basic thermostatting and barostatting, this fix can also create a chain of thermostats coupled to the particle thermostat, and another chain of thermostats coupled to the barostat variables. The barostat can be coupled to the overall box volume, or to individual dimensions, including the xy, xz and yz tilt dimensions. The external pressure of the barostat can be specified as either a scalar pressure (isobaric ensemble) or as components of a symmetric stress tensor (constant stress ensemble). When used correctly, the time-averaged temperature and stress tensor of the particles will match the target values specified by Tstart/Tstop and Pstart/Pstop.
The equations of motion used are those of Shinoda et al in (Shinoda), which combine the hydrostatic equations of Martyna, Tobias and Klein in (Martyna) with the strain energy proposed by Parrinello and Rahman in (Parrinello). The time integration schemes closely follow the time-reversible measure-preserving Verlet and rRESPA integrators derived by Tuckerman et al in (Tuckerman).

The thermostat parameters are specified using the temp keyword. Other thermostat-related keywords are tchain, tloop and drag, which are discussed below.

The thermostat is applied to only the translational degrees of freedom for the particles. The translational degrees of freedom can also have a bias velocity removed before thermostatting takes place; see the description below. The desired temperature at each timestep is a ramped value during the run from $T_{start}$ to $T_{stop}$. The $T_{damp}$ parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 10.0 means to relax the temperature in a timespan of (roughly) 10 time units (e.g. $\tau$ or fs or ps - see the units command). The atoms in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the integration.

Note: A Nose-Hoover thermostat will not work well for arbitrary values of $T_{damp}$. If $T_{damp}$ is too small, the temperature can fluctuate wildly; if it is too large, the temperature will take a very long time to equilibrate. A good choice for many models is a $T_{damp}$ of around 100 timesteps. Note that this is NOT the same as 100 time units for most units settings.

The barostat parameters are specified using one or more of the iso, aniso, tri, x, y, z, xy, xz, yz, and couple keywords. These keywords give you the ability to specify all 6 components of an external stress tensor, and to couple various of these components together so that the dimensions they represent are varied together during a constant-pressure simulation.

Other barostat-related keywords are pchain, mtk, ploop, nreset, drag, and dilate, which are discussed below.

Orthogonal simulation boxes have 3 adjustable dimensions (x,y,z). Triclinic (non-orthogonal) simulation boxes have 6 adjustable dimensions (x,y,z,xy,xz,yz). The create_box, read data, and read_restart commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the xy,xz,yz tilt factors.

The target pressures for each of the 6 components of the stress tensor can be specified independently via the $x$, $y$, $z$, $xy$, $xz$, $yz$ keywords, which correspond to the 6 simulation box dimensions. For each component, the external pressure or tensor component at each timestep is a ramped value during the run from $P_{start}$ to $P_{stop}$. If a target pressure is specified for a component, then the corresponding box dimension will change during a simulation. For example, if the $y$ keyword is used, the y-box length will change. If the $xy$ keyword is used, the xy tilt factor will change. A box dimension will not change if that component is not specified, although you have the option to change that dimension via the fix deform command.

Note that in order to use the $xy$, $xz$, or $yz$ keywords, the simulation box must be triclinic, even if its initial tilt factors are 0.0.

For all barostat keywords, the $P_{damp}$ parameter operates like the $T_{damp}$ parameter, determining the time scale on which pressure is relaxed. For example, a value of 10.0 means to relax the pressure in a timespan of (roughly) 10 time units (e.g. $\tau$ or fs or ps - see the units command).

Note: A Nose-Hoover barostat will not work well for arbitrary values of $P_{damp}$. If $P_{damp}$ is too small, the pressure and volume can fluctuate wildly; if it is too large, the pressure will take a very long time to equilibrate. A good choice for many models is a $P_{damp}$ of around 1000 timesteps. However, note that $P_{damp}$ is specified in time units, and that timesteps are NOT the same as time units for most units settings.
Regardless of what atoms are in the fix group (the only atoms which are time integrated), a global pressure or stress tensor is computed for all atoms. Similarly, when the size of the simulation box is changed, all atoms are re-scaled to new positions, unless the keyword *dilate* is specified with a *dilate-group-ID* for a group that represents a subset of the atoms. This can be useful, for example, to leave the coordinates of atoms in a solid substrate unchanged and controlling the pressure of a surrounding fluid. This option should be used with care, since it can be unphysical to dilate some atoms and not others, because it can introduce large, instantaneous displacements between a pair of atoms (one dilated, one not) that are far from the dilation origin. Also note that for atoms not in the fix group, a separate time integration fix like *fix nve* or *fix nvt* can be used on them, independent of whether they are dilated or not.

The *couple* keyword allows two or three of the diagonal components of the pressure tensor to be “coupled” together. The value specified with the keyword determines which are coupled. For example, *xz* means the $P_{xx}$ and $P_{zz}$ components of the stress tensor are coupled. *Xyz* means all 3 diagonal components are coupled. Coupling means two things: the instantaneous stress will be computed as an average of the corresponding diagonal components, and the coupled box dimensions will be changed together in lockstep, meaning coupled dimensions will be dilated or contracted by the same percentage every timestep. The *Pstart*, *Pstop*, and *Pdamp* parameters for any coupled dimensions must be identical. *Couple xyz* can be used for a 2d simulation; the $z$ dimension is simply ignored.

The *iso*, *aniso*, and *tri* keywords are simply shortcuts that are equivalent to specifying several other keywords together. The keyword *iso* means couple all 3 diagonal components together when pressure is computed (hydrostatic pressure), and dilate/contract the dimensions together. Using “*iso Pstart Pstop Pdamp*” is the same as specifying these 4 keywords:

```
x Pstart Pstop Pdamp
y Pstart Pstop Pdamp
z Pstart Pstop Pdamp
couple xyz
```

The keyword *aniso* means $x$, $y$, and $z$ dimensions are controlled independently using the $P_{xx}$, $P_{yy}$, and $P_{zz}$ components of the stress tensor as the driving forces, and the specified scalar external pressure. Using “*aniso Pstart Pstop Pdamp*” is the same as specifying these 4 keywords:

```
x Pstart Pstop Pdamp
y Pstart Pstop Pdamp
z Pstart Pstop Pdamp
couple none
```

The keyword *tri* means $x$, $y$, $z$, $xy$, $xz$, and $yz$ dimensions are controlled independently using their individual stress components as the driving forces, and the specified scalar pressure as the external normal stress. Using “*tri Pstart Pstop Pdamp*” is the same as specifying these 7 keywords:

```
x Pstart Pstop Pdamp
y Pstart Pstop Pdamp
z Pstart Pstop Pdamp
xy 0.0 0.0 Pdamp
yz 0.0 0.0 Pdamp
xz 0.0 0.0 Pdamp
couple none
```

In some cases (e.g. for solids) the pressure (volume) and/or temperature of the system can oscillate undesirably when a Nose/Hoover barostat and thermostat is applied. The optional *drag* keyword will damp these oscillations, although it alters the Nose/Hoover equations. A value of 0.0 (no drag) leaves the Nose/Hoover formalism unchanged. A non-zero value adds a drag term; the larger the value specified, the greater the damping effect. Performing a short run and

17.111. *fix npt/cauchy command*
monitoring the pressure and temperature is the best way to determine if the drag term is working. Typically a value between 0.2 to 2.0 is sufficient to damp oscillations after a few periods. Note that use of the drag keyword will interfere with energy conservation and will also change the distribution of positions and velocities so that they do not correspond to the nominal NVT, NPT, or NPH ensembles.

An alternative way to control initial oscillations is to use chain thermostats. The keyword `tchain` determines the number of thermostats in the particle thermostat. A value of 1 corresponds to the original Nose-Hoover thermostat. The keyword `pchain` specifies the number of thermostats in the chain thermostatting the barostat degrees of freedom. A value of 0 corresponds to no thermostatting of the barostat variables.

The `mtk` keyword controls whether or not the correction terms due to Martyna, Tuckerman, and Klein are included in the equations of motion (Martyna). Specifying no reproduces the original Hoover barostat, whose volume probability distribution function differs from the true NPT and NPH ensembles by a factor of 1/V. Hence using yes is more correct, but in many cases the difference is negligible.

The keyword `tloop` can be used to improve the accuracy of integration scheme at little extra cost. The initial and final updates of the thermostat variables are broken up into `tloop` sub-steps, each of length `dt/tloop`. This corresponds to using a first-order Suzuki-Yoshida scheme (Tuckerman). The keyword `ploop` does the same thing for the barostat thermostat.

The keyword `nreset` controls how often the reference dimensions used to define the strain energy are reset. If this keyword is not used, or is given a value of zero, then the reference dimensions are set to those of the initial simulation domain and are never changed. If the simulation domain changes significantly during the simulation, then the final average pressure tensor will differ significantly from the specified values of the external stress tensor. A value of `nstep` means that every `nstep` timesteps, the reference dimensions are set to those of the current simulation domain.

The `scaleyz`, `scalexz`, and `scalexy` keywords control whether or not the corresponding tilt factors are scaled with the associated box dimensions when barostatting triclinic periodic cells. The default values yes will turn on scaling, which corresponds to adjusting the linear dimensions of the cell while preserving its shape. Choosing no ensures that the tilt factors are not scaled with the box dimensions. See below for restrictions and default values in different situations. In older versions of LAMMPS, scaling of tilt factors was not performed. The old behavior can be recovered by setting all three scale keywords to no.

The `flip` keyword allows the tilt factors for a triclinic box to exceed half the distance of the parallel box length, as discussed below. If the `flip` value is set to yes, the bound is enforced by flipping the box when it is exceeded. If the `flip` value is set to no, the tilt will continue to change without flipping. Note that if applied stress induces large deformations (e.g. in a liquid), this means the box shape can tilt dramatically and LAMMPS will run less efficiently, due to the large volume of communication needed to acquire ghost atoms around a processor’s irregular-shaped sub-domain. For extreme values of tilt, LAMMPS may also lose atoms and generate an error.

The fixedpoint keyword specifies the fixed point for barostat volume changes. By default, it is the center of the box. Whatever point is chosen will not move during the simulation. For example, if the lower periodic boundaries pass through (0,0,0), and this point is provided to fixedpoint, then the lower periodic boundaries will remain at (0,0,0), while the upper periodic boundaries will move twice as far. In all cases, the particle trajectories are unaffected by the chosen value, except for a time-dependent constant translation of positions.

---

**Note:** Using a barostat coupled to tilt dimensions xy, xz, yz can sometimes result in arbitrarily large values of the tilt dimensions, i.e. a dramatically deformed simulation box. LAMMPS allows the tilt factors to grow a small amount beyond the normal limit of half the box length (0.6 times the box length), and then performs a box “flip” to an equivalent periodic cell. See the discussion of the `flip` keyword above, to allow this bound to be exceeded, if desired.

The flip operation is described in more detail in the page for `fix deform`. Both the barostat dynamics and the atom trajectories are unaffected by this operation. However, if a tilt factor is incremented by a large amount (1.5 times the box length) on a single timestep, LAMMPS can not accommodate this event and will terminate the simulation with an error. This error typically indicates that there is something badly wrong with how the simulation was constructed, such as specifying values of Pstart that are too far from the current stress value, or specifying a timestep that is too large.
Triclinic barostatting should be used with care. This also is true for other barostat styles, although they tend to be more forgiving of insults. In particular, it is important to recognize that equilibrium liquids can not support a shear stress and that equilibrium solids can not support shear stresses that exceed the yield stress.

One exception to this rule is if the first dimension in the tilt factor (x for xy) is non-periodic. In that case, the limits on the tilt factor are not enforced, since flipping the box in that dimension does not change the atom positions due to non-periodicity. In this mode, if you tilt the system to extreme angles, the simulation will simply become inefficient due to the highly skewed simulation box.

Note: Unlike the fix temp/berendsen command which performs thermostatting but NO time integration, this fix performs thermostatting/barostatting AND time integration. Thus you should not use any other time integration fix, such as fix nve on atoms to which this fix is applied. Likewise, fix npt/cauchy should not normally be used on atoms that also have their temperature controlled by another fix - e.g. by fix langevin or fix temp/rescale commands.

See the Howto thermostat and Howto barostat doc pages for a discussion of different ways to compute temperature and perform thermostatting and barostatting.

This fix compute a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp” and “pressure”, as if one of these sets of commands had been issued:

```
compute fix-ID_temp all temp
compute fix-ID_press all pressure fix-ID_temp
```

The group for both the new temperature and pressure compute is “all” since pressure is computed for the entire system. See the compute temp and compute pressure commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix_ID + underscore + “press”.

Note that these are NOT the computes used by thermodynamic output (see the thermo_style command) with ID = thermo_temp and thermo_press. This means you can change the attributes of these fix’s temperature or pressure via the compute_modify command. Or you can print this temperature or pressure during thermodynamic output via the thermo_style custom command using the appropriate compute-ID. It also means that changing attributes of thermo_temp or thermo_press will have no effect on this fix.

Like other fixes that perform thermostatting, this fix can be used with compute commands that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial region, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the fix_modify command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual compute temp commands to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

This fix can be used with either the verlet or respa integrators. When using this fix with respa, LAMMPS uses an integrator constructed according to the following factorization of the Liouville propagator (for two rRESPA levels):

\[
\exp(iL\Delta t) = \hat{E} \exp \left( iL_{\text{T-baro}} \frac{\Delta t}{2} \right) \exp \left( iL_{\text{T-part}} \frac{\Delta t}{2} \right) \exp \left( iL_{e,2} \frac{\Delta t}{2} \right) \exp \left( iL_{2} \frac{\Delta t}{2} \right) \\
\times \left[ \exp \left( iL_{2}^{(1)} \frac{\Delta t}{2n} \right) \exp \left( iL_{e,1} \frac{\Delta t}{2n} \right) \exp \left( iL_{1} \frac{\Delta t}{n} \right) \exp \left( iL_{e,1} \frac{\Delta t}{2n} \right) \exp \left( iL_{2}^{(1)} \frac{\Delta t}{2n} \right) \right]^n \\
\times \exp \left( iL_{2} \frac{\Delta t}{2} \right) \exp \left( iL_{e,2} \frac{\Delta t}{2} \right) \exp \left( iL_{\text{T-part}} \frac{\Delta t}{2} \right) \exp \left( iL_{\text{T-baro}} \frac{\Delta t}{2} \right) \\
+ \mathcal{O}(\Delta t^3)
\]
This factorization differs somewhat from that of Tuckerman et al, in that the barostat is only updated at the outermost rRESPA level, whereas Tuckerman’s factorization requires splitting the pressure into pieces corresponding to the forces computed at each rRESPA level. In theory, the latter method will exhibit better numerical stability. In practice, because Pdamp is normally chosen to be a large multiple of the outermost rRESPA timestep, the barostat dynamics are not the limiting factor for numerical stability. Both factorizations are time-reversible and can be shown to preserve the phase space measure of the underlying non-Hamiltonian equations of motion.

Note: Under NPT dynamics, for a system with zero initial total linear momentum, the total momentum fluctuates close to zero. It may occasionally undergo brief excursions to non-negligible values, before returning close to zero. Over long simulations, this has the effect of causing the center-of-mass to undergo a slow random walk. This can be mitigated by resetting the momentum at infrequent intervals using the fix momentum command.

### 17.111.4 Restart, fix modify, output, run start/stop, minimize info

This fix writes the state of all the thermostat and barostat variables to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify temp and press options are supported by this fix. You can use them to assign a compute you have defined to this fix which will be used in its thermostatting or barostatting procedure, as described above. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

Note: If both the temp and press keywords are used in a single thermo_modify command (or in two separate commands), then the order in which the keywords are specified is important. Note that a pressure compute defines its own temperature compute as an argument when it is specified. The temp keyword will override this (for the pressure compute being used by fix npt), but only if the temp keyword comes after the press keyword. If the temp keyword comes before the press keyword, then the new pressure compute specified by the press keyword will be unaffected by the temp setting.

The cumulative energy change in the system imposed by this fix, due to thermostatting and/or barostatting, is included in the thermodynamic output keywords ecouple and econserve. See the thermo_style page for details.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

This fix also computes a global vector of quantities, which can be accessed by various output commands. The vector values are “intensive”.

The vector stores internal Nose/Hoover thermostat and barostat variables. The number and meaning of the vector values depends on which fix is used and the settings for keywords tchain and pchain, which specify the number of Nose/Hoover chains for the thermostat and barostat. If no thermostatting is done, then tchain is 0. If no barostatting is done, then pchain is 0. In the following list, “ndof” is 0, 1, 3, or 6, and is the number of degrees of freedom in the barostat. Its value is 0 if no barostat is used, else its value is 6 if any off-diagonal stress tensor component is barostatted, else its value is 1 if couple xyz is used or couple xy for a 2d simulation, otherwise its value is 3.

The order of values in the global vector and their meaning is as follows. The notation means there are tchain values for eta, followed by tchain for eta_dot, followed by ndof for omega, etc:

- \( \text{eta}[\text{tchain}] = \) particle thermostat displacements (unitless)
- \( \text{eta_dot}[\text{tchain}] = \) particle thermostat velocities (1/time units)
• omega[ndof] = barostat displacements (unitless)
• omega_dot[ndof] = barostat velocities (1/time units)
• etap[pchain] = barostat thermostat displacements (unitless)
• etap_dot[pchain] = barostat thermostat velocities (1/time units)
• PE_omega[ndof] = potential energy of each barostat displacement (energy units)
• KE_omega_dot[ndof] = kinetic energy of each barostat velocity (energy units)
• PE_etap[pchain] = potential energy of each barostat thermostat displacement (energy units)
• KE_etap_dot[pchain] = kinetic energy of each barostat thermostat velocity (energy units)
• PE_strain[1] = scalar strain energy (energy units)

This fix can ramp its external temperature and pressure over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

17.111.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

X, y, z cannot be barostatted if the associated dimension is not periodic. Xy, xz, and yz can only be barostatted if the simulation domain is triclinic and the second dimension in the keyword (y dimension in xy) is periodic. Z, xz, and yz, cannot be barostatted for 2D simulations. The create_box, read data, and read_restart commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the xy,xz,yz tilt factors.

For the temp keyword, the final Tstop cannot be 0.0 since it would make the external T = 0.0 at some timestep during the simulation which is not allowed in the Nose/Hoover formulation.

The scaleyz yes and scalexz yes keyword/value pairs can not be used for 2D simulations. scaleyz yes, scalexz yes, and scalexy yes options can only be used if the second dimension in the keyword is periodic, and if the tilt factor is not coupled to the barostat via keywords tri, yz, xz, and xy.

The alpha keyword modifies the barostat as per Miller et al. (Miller) so that the Cauchy stress is controlled. alpha is the non-dimensional parameter, typically set to 0.001 or 0.01 that determines how aggressively the algorithm drives the system towards the set Cauchy stresses. Larger values of alpha will modify the system more quickly, but can lead to instabilities. Smaller values will lead to longer convergence time. Since alpha also influences how much the stress fluctuations deviate from the equilibrium fluctuations, it should be set as small as possible.

A continue value of yes indicates that the fix is subsequent to a previous run with the npt/cauchy fix, and the intention is to continue from the converged stress state at the end of the previous run. This may be required, for example, when implementing a multi-step loading/unloading sequence over several fixes.

Setting alpha to zero is not permitted. To “turn off” the cauchystat control and thus restore the equilibrium stress fluctuations, two subsequent fixes should be used. In the first, fix npt/cauchy is used and the simulation box equilibrates to the correct shape for the desired stresses. In the second, fix npt is used instead which uses the original Parrinello-Rahman algorithm, but now with the corrected simulation box shape from using fix npt/cauchy.

This fix can be used with dynamic groups as defined by the group command. Likewise it can be used with groups to which atoms are added or deleted over time, e.g. a deposition simulation. However, the conservation properties of the
thermostat and barostat are defined for systems with a static set of atoms. You may observe odd behavior if the atoms in a group vary dramatically over time or the atom count becomes very small.

17.112.3 Description

Perform constant NPT integration to update position, velocity, and angular velocity each timestep for finite-size spherical particles in the group using a Nose/Hoover temperature thermostat and Nose/Hoover pressure barostat. $P$ is pressure; $T$ is temperature. This creates a system trajectory consistent with the isothermal-isobaric ensemble.

This fix differs from the fix npt command, which assumes point particles and only updates their position and velocity. The thermostat is applied to both the translational and rotational degrees of freedom for the spherical particles, assuming a compute is used which calculates a temperature that includes the rotational degrees of freedom (see below). The translational degrees of freedom can also have a bias velocity removed from them before thermostatting takes place; see the description below.

If the disc keyword is used, then each particle is treated as a 2d disc (circle) instead of as a sphere. This is only possible for 2d simulations, as defined by the dimension keyword. The only difference between discs and spheres in this context is their moment of inertia, as used in the time integration.

Additional parameters affecting the thermostat and barostat are specified by keywords and values documented with the fix npt command. See, for example, discussion of the temp, iso, aniso, and dilate keywords.

The particles in the fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the NPT integration.

Regardless of what particles are in the fix group, a global pressure is computed for all particles. Similarly, when the size of the simulation box is changed, all particles are re-scaled to new positions, unless the keyword dilate is specified with a value of partial, in which case only the particles in the fix group are re-scaled. The latter can be useful for leaving the coordinates of particles in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

This fix computes a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp/sphere” and “pressure”, as if these commands had been issued:

```
compute fix-ID_temp all temp/sphere
compute fix-ID_press all pressure fix-ID_temp
```

See the compute temp/sphere and compute pressure commands for details. Note that the IDs of the new computes are the fix-ID + underscore + “temp” or fix_ID + underscore + “press”, and the group for the new computes is “all” since pressure is computed for the entire system.

Note that these are NOT the computes used by thermodynamic output (see the thermo_style command) with ID = thermo_temp and thermo_press. This means you can change the attributes of this fix’s temperature or pressure via the compute_modify command or print this temperature or pressure during thermodynamic output via the thermo_style custom command using the appropriate compute-ID. It also means that changing attributes of thermo_temp or thermo_press will have no effect on this fix.

Like other fixes that perform thermostatting, this fix can be used with compute commands that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial region, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the fix_modify command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual compute temp commands to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.
These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 17.112.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat and barostat to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify temp and press options are supported by this fix. You can use them to assign a compute you have defined to this fix which will be used in its thermostatting or barostatting procedure. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

The cumulative energy change in the system imposed by this fix is included in the thermodynamic output keywords ecouple and econserve. See the thermo_style doc page for details.

This fix computes the same global scalar and global vector of quantities as does the fix npt command.

This fix can ramp its target temperature and pressure over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

### 17.112.5 Restrictions

This fix requires that atoms store torque and angular velocity (omega) and a radius as defined by the atom_style sphere command.

All particles in the group must be finite-size spheres. They cannot be point particles.

Use of the disc keyword is only allowed for 2d simulations, as defined by the dimension keyword.

### 17.112.6 Related commands

fix npt, fix nve_sphere, fix nvt_sphere, fix npt_asphere, fix_modify

### 17.112.7 Default

none
17.113 fix numdiff command

17.113.1 Syntax

```
fix ID group-ID numdiff Nevery delta
```

- ID, group-ID are documented in `fix` command
- numdiff = style name of this fix command
- Nevery = calculate force by finite difference every this many timesteps
- delta = size of atom displacements (distance units)

17.113.2 Examples

```
fix 1 all numdiff 10 1e-6
fix 1 movegroup numdiff 100 0.01
```

17.113.3 Description

Calculate forces through finite difference calculations of energy versus position. These forces can be compared to analytic forces computed by pair styles, bond styles, etc. This can be useful for debugging or other purposes.

The group specified with the command means only atoms within the group have their averages computed. Results are set to 0.0 for atoms not in the group.

This fix performs a loop over all atoms in the group. For each atom and each component of force it adds `delta` to the position, and computes the new energy of the entire system. It then subtracts `delta` from the original position and again computes the new energy of the system. It then restores the original position. That component of force is calculated as the difference in energy divided by two times `delta`.

**Note:** It is important to choose a suitable value for `delta`, the magnitude of atom displacements that are used to generate finite difference approximations to the exact forces. For typical systems, a value in the range of 1 part in 1e4 to 1e5 of the typical separation distance between atoms in the liquid or solid state will be sufficient. However, the best value will depend on a multitude of factors including the stiffness of the interatomic potential, the thermodynamic state of the material being probed, and so on. The only way to be sure that you have made a good choice is to do a sensitivity study on a representative atomic configuration, sweeping over a wide range of values of `delta`. If `delta` is too small, the output forces will vary erratically due to truncation effects. If `delta` is increased beyond a certain point, the output forces will start to vary smoothly with `delta`, due to growing contributions from higher order derivatives. In between these two limits, the numerical force values should be largely independent of `delta`.

**Note:** The cost of each energy evaluation is essentially the cost of an MD timestep. Thus invoking this fix once for a 3d system has a cost of 6N timesteps, where N is the total number of atoms in the system. So this fix can be very expensive to use for large systems. One expedient alternative is to define the fix for a group containing only a few atoms.

The `Nevery` argument specifies on what timesteps the force will be used calculated by finite difference.
The *delta* argument specifies the size of the displacement each atom will undergo.

### 17.113.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix_modify* options are relevant to this fix. This fix produces a per-atom array which can be accessed by various *output commands*, which stores the components of the force on each atom as calculated by finite difference. The per-atom values can only be accessed on timesteps that are multiples of *Nevery* since that is when the finite difference forces are calculated. See the examples in *examples/numpdiff* directory to see how this fix can be used to directly compare with the analytic forces computed by LAMMPS. The array values calculated by this compute will be in force *units*.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is invoked during *energy minimization*.

### 17.113.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 17.114 fix numdiff/virial command

#### 17.114.1 Syntax

```
fix ID group-ID numdiff/virial Nevery delta
```

- *ID, group-ID are documented in *fix command*
- *numdiff/virial = style name of this fix command*
- *Nevery = calculate virial by finite difference every this many timesteps*
- *delta = magnitude of strain fields (dimensionless)*
17.114.2 Examples

```
fix 1 all numdiff/stress 10 1e-6
```

17.114.3 Description

Calculate the virial stress tensor through a finite difference calculation of energy versus strain. These values can be compared to the analytic virial tensor computed by pair styles, bond styles, etc. This can be useful for debugging or other purposes. The specified group must be “all”.

This fix applies linear strain fields of magnitude $\delta$ to all the atoms relative to a point at the center of the box. The strain fields are in six different directions, corresponding to the six Cartesian components of the stress tensor defined by LAMMPS. For each direction it applies the strain field in both the positive and negative senses, and the new energy of the entire system is calculated after each. The difference in these two energies divided by two times $\delta$, approximates the corresponding component of the virial stress tensor, after applying a suitable unit conversion.

**Note:** It is important to choose a suitable value for $\delta$, the magnitude of strains that are used to generate finite difference approximations to the exact virial stress. For typical systems, a value in the range of $1$ part in $1e5$ to $1e6$ will be sufficient. However, the best value will depend on a multitude of factors including the stiffness of the interatomic potential, the thermodynamic state of the material being probed, and so on. The only way to be sure that you have made a good choice is to do a sensitivity study on a representative atomic configuration, sweeping over a wide range of values of $\delta$. If $\delta$ is too small, the output values will vary erratically due to truncation effects. If $\delta$ is increased beyond a certain point, the output values will start to vary smoothly with $\delta$, due to growing contributions from higher order derivatives. In between these two limits, the numerical virial values should be largely independent of $\delta$.

The $Nevery$ argument specifies on what timesteps the force will be used calculated by finite difference.

The $\delta$ argument specifies the size of the displacement each atom will undergo.

17.114.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix.

This fix produces a global vector which can be accessed by various output commands, which stores the components of the virial stress tensor as calculated by finite difference. The global vector can only be accessed on timesteps that are multiples of $Nevery$ since that is when the finite difference virial is calculated. See the examples in examples/numdiff directory to see how this fix can be used to directly compare with the analytic virial stress tensor computed by LAMMPS.

The order of the virial stress tensor components is $xx$, $yy$, $zz$, $yz$, $xz$, and $xy$, consistent with Voigt notation. Note that the vector produced by compute pressure uses a different ordering, with $yz$ and $xy$ swapped.

The vector values calculated by this compute are “intensive”. The vector values will be in pressure units.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is invoked during energy minimization.
17.114.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

17.120 fix nve/bpm/sphere command

17.120.1 Syntax

```plaintext
fix ID group-ID nve/bpm/sphere
```

- ID, group-ID are documented in fix command
- nve/bpm/sphere = style name of this fix command
- zero or more keyword/value pairs may be appended
- keyword = disc
  - disc value = none = treat particles as 2d discs, not spheres

17.120.2 Examples

```plaintext
fix 1 all nve/bpm/sphere
fix 1 all nve/bpm/sphere disc
```

17.120.3 Description

Perform constant NVE integration to update position, velocity, angular velocity, and quaternion orientation for finite-size spherical particles in the group each timestep. \( V \) is volume; \( E \) is energy. This creates a system trajectory consistent with the microcanonical ensemble.

This fix differs from the fix nve command, which assumes point particles and only updates their position and velocity. It also differs from the fix nve/sphere command which assumes finite-size spheroid particles which do not store a quaternion. It thus does not update a particle’s orientation or quaternion.

If the disc keyword is used, then each particle is treated as a 2d disc (circle) instead of as a sphere. This is only possible for 2d simulations, as defined by the dimension keyword. The only difference between discs and spheres in this context is their moment of inertia, as used in the time integration.
17.120.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.120.5 Restrictions

This fix requires that atoms store torque, angular velocity (omega), a radius, and a quaternion as defined by the atom_style bpm/sphere command.

All particles in the group must be finite-size spheres with quaternions. They cannot be point particles.

Use of the disc keyword is only allowed for 2d simulations, as defined by the dimension keyword.

17.121.2 Examples

```latex
fix 1 all nve/dot
```
17.121.3 Description

Apply a rigid-body integrator as described in (Davidchack) to a group of atoms, but without Langevin dynamics. This command performs Molecular dynamics (MD) via a velocity-Verlet algorithm and an evolution operator that rotates the quaternion degrees of freedom, similar to the scheme outlined in (Miller).

This command is the equivalent of the fix nve/dotc/langevin without damping and noise and can be used to determine the stability range in a NVE ensemble prior to using the Langevin-type DOTC-integrator (see also fix nve/dotc/langevin). The command is equivalent to the fix nve. The particles are always considered to have a finite size.

An example input file can be found in /examples/PACKAGES/cgdna/examples/duplex1/. Further details of the implementation and stability of the integrator are contained in (Henrich). The preprint version of the article can be found here.

17.121.4 Restrictions

These pair styles can only be used if LAMMPS was built with the CG-DNA package and the MOLECULE and ASPIHERE package. See the Build package page for more info.

17.121.5 Related commands

17.122.1 Syntax

fix ID group-ID nve/dotc/langevin Tstart Tstop damp seed keyword value

- ID, group-ID are documented in fix command
- nve/dotc/langevin = style name of this fix command
- Tstart, Tstop = desired temperature at start/end of run (temperature units)
- damp = damping parameter (time units)
- seed = random number seed to use for white noise (positive integer)
- keyword = angmom
angmom value = factor
  factor = do thermostat rotational degrees of freedom via the angular momentum and apply numeric scale factor as discussed below

17.122.2 Examples

```
fix 1 all nve/dotc/langevin 1.0 1.0 0.03 457145 angmom 10
fix 1 all nve/dotc/langevin 0.1 0.1 78.9375 457145 angmom 10
```

17.122.3 Description

Apply a rigid-body Langevin-type integrator of the kind “Langevin C” as described in (Davidchack) to a group of atoms, which models an interaction with an implicit background solvent. This command performs Brownian dynamics (BD) via a technique that splits the integration into a deterministic Hamiltonian part and the Ornstein-Uhlenbeck process for noise and damping. The quaternion degrees of freedom are updated though an evolution operator which performs a rotation in quaternion space, preserves the quaternion norm and is akin to (Miller).

In terms of syntax this command has been closely modelled on the fix langevin and its angmom option. But it combines the fix nve and the fix langevin in one single command. The main feature is improved stability over the standard integrator, permitting slightly larger timestep sizes.

**Note:** Unlike the fix langevin this command performs also time integration of the translational and quaternion degrees of freedom.

The total force on each atom will have the form:

\[
F = F_c + F_f + F_r
\]

\[
F_f = - \frac{m \text{ damp}}{v} \cdot v
\]

\[
F_r \propto \sqrt{\frac{k_B T m}{dt \text{ damp}}}
\]

\(F_c\) is the conservative force computed via the usual inter-particle interactions (pair_style, bond_style, etc). The \(F_f\) and \(F_r\) terms are implicitly taken into account by this fix on a per-particle basis.

\(F_f\) is a frictional drag or viscous damping term proportional to the particle’s velocity. The proportionality constant for each atom is computed as \(\frac{m \text{ damp}}{\text{ damp}}\), where \(m\) is the mass of the particle and damp is the damping factor specified by the user.

\(F_r\) is a force due to solvent atoms at a temperature \(T\) randomly bumping into the particle. As derived from the fluctuation/dissipation theorem, its magnitude as shown above is proportional to \(\sqrt{\frac{k_B T m}{dt \text{ damp}}}\), where \(k_B\) is the Boltzmann constant, \(T\) is the desired temperature, \(m\) is the mass of the particle, \(dt\) is the timestep size, and damp is the damping factor. Random numbers are used to randomize the direction and magnitude of this force as described in (Dunweg), where a uniform random number is used (instead of a Gaussian random number) for speed.

\(T_{\text{start}}\) and \(T_{\text{stop}}\) have to be constant values, i.e. they cannot be variables. If used together with the oxDNA force field for coarse-grained simulation of DNA please note that \(T = 0.1\) in oxDNA units corresponds to \(T = 300\) K.

The damp parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 0.03 means to relax the temperature in a timespan of (roughly) 0.03 time units \(\tau\) (see the units command). The damp factor can be thought of as inversely related to the viscosity of the solvent, i.e. a small relaxation time implies a
high-viscosity solvent and vice versa. See the discussion about gamma and viscosity in the documentation for the fix viscous command for more details. Note that the value 78.9375 in the second example above corresponds to a diffusion constant, which is about an order of magnitude larger than realistic ones. This has been used to sample configurations faster in Brownian dynamics simulations.

The random seed must be a positive integer. A Marsaglia random number generator is used. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.

The keyword/value option has to be used in the following way:

This fix has to be used together with the angmom keyword. The particles are always considered to have a finite size. The keyword angmom enables thermostating of the rotational degrees of freedom in addition to the usual translational degrees of freedom.

The scale factor after the angmom keyword gives the ratio of the rotational to the translational friction coefficient.

An example input file can be found in examples/PACKAGES/cgdna/examples/duplex2/. Further details of the implementation and stability of the integrators are contained in (Henrich). The preprint version of the article can be found here.

17.122.4 Restrictions

fix 1 all nve/limit 0.1

17.124.3 Description

Perform constant NVE updates of position and velocity for atoms in the group each timestep. A limit is imposed on the maximum distance an atom can move in one timestep. This is useful when starting a simulation with a configuration containing highly overlapped atoms. Normally this would generate huge forces which would blow atoms out of the simulation box, causing LAMMPS to stop with an error.

Using this fix can overcome that problem. Forces on atoms must still be computable (which typically means 2 atoms must have a separation distance > 0.0). But large velocities generated by large forces are reset to a value that corresponds to a displacement of length xmax in a single timestep. Xmax is specified in distance units; see the units command for details. The value of xmax should be consistent with the neighbor skin distance and the frequency of neighbor list re-building, so that pairwise interactions are not missed on successive timesteps as atoms move. See the neighbor and neigh_modify commands for details.

Note that if a velocity reset occurs the integrator will not conserve energy. On steps where no velocity resets occur, this integrator is exactly like the fix nve command. Since forces are unaltered, pressures computed by thermodynamic output will still be very large for overlapped configurations.

Note: You should not use fix shake in conjunction with this fix. That is because fix shake applies constraint forces based on the predicted positions of atoms after the next timestep. It has no way of knowing the timestep may change due to this fix, which will cause the constraint forces to be invalid. A better strategy is to turn off fix shake when performing initial dynamics that need this fix, then turn fix shake on when doing normal dynamics with a fixed-size timestep.

17.124.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. This fix computes a global scalar which can be accessed by various output commands. The scalar is the count of how many updates of atom’s velocity/position were limited by the maximum distance criterion. This should be roughly the number of atoms so affected, except that updates occur at both the beginning and end of a timestep in a velocity Verlet time-stepping algorithm. This is a cumulative quantity for the current run, but is re-initialized to zero each time a run is performed. The scalar value calculated by this fix is “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.
17.124.5 Restrictions

17.125 fix nve/line command

17.125.1 Syntax

fix ID group-ID nve/line

- ID, group-ID are documented in fix command
- nve/line = style name of this fix command

17.125.2 Examples

fix 1 all nve/line

17.125.3 Description

Perform constant NVE integration to update position, velocity, orientation, and angular velocity for line segment particles in the group each timestep. V is volume; E is energy. This creates a system trajectory consistent with the microcanonical ensemble. See Howto spherical page for an overview of using line segment particles.

This fix differs from the fix nve command, which assumes point particles and only updates their position and velocity.

17.125.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.
17.125.5 Restrictions

This fix is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This fix requires that particles be line segments as defined by the atom_style line command.

- ID, group-ID are documented in fix command
- nve/manifold/rattle = style name of this fix command
- tol = tolerance to which Newton iteration must converge
- maxit = maximum number of iterations to perform
- manifold = name of the manifold
- manifold-args = parameters for the manifold
- one or more keyword/value pairs may be appended
  
  keyword = every
  
  every values = N
  
  N = print info about iteration every N steps. N = 0 means no output

17.126.2 Examples

fix 1 all nve/manifold/rattle 1e-4 10 sphere 5.0
fix step all nve/manifold/rattle 1e-8 100 ellipsoid 2.5 2.5 5.0 every 25
17.126.3 Description

Perform constant NVE integration to update position and velocity for atoms constrained to a curved surface (manifold) in the group each timestep. The constraint is handled by RATTLE (Andersen) written out for the special case of single-particle constraints as explained in (Paquay). V is volume; E is energy. This way, the dynamics of particles constrained to curved surfaces can be studied. If combined with fix langevin, this generates Brownian motion of particles constrained to a curved surface. For a list of currently supported manifolds and their parameters, see the Howto manifold doc page.

Note that the particles must initially be close to the manifold in question. If not, RATTLE will not be able to iterate until the constraint is satisfied, and an error is generated. For simple manifolds this can be achieved with region and create_atoms commands, but for more complex surfaces it might be more useful to write a script.

The manifold args may be equal-style variables, like so:

```
variable R equal "ramp(5.0,3.0)"
fix shrink_sphere all nve/manifold/rattle 1e-4 10 sphere v_R
```

In this case, the manifold parameter will change in time according to the variable. This is not a problem for the time integrator as long as the change of the manifold is slow with respect to the dynamics of the particles. Note that if the manifold has to exert work on the particles because of these changes, the total energy might not be conserved.

17.126.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.126.5 Restrictions

This fix is part of the MANIFOLD package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

• nve/noforce = style name of this fix command

17.127.2 Examples

| fix 3 wall nve/noforce |

17.127.3 Description

Perform updates of position, but not velocity for atoms in the group each timestep. In other words, the force on the atoms is ignored and their velocity is not updated. The atom velocities are used to update their positions.

This can be useful for wall atoms, when you set their velocities, and want the wall to move (or stay stationary) in a prescribed fashion.

This can also be accomplished via the fix setforce command, but with fix nve/noforce, the forces on the wall atoms are unchanged, and can thus be printed by the dump command or queried with an equal-style variable that uses the fcm() group function to compute the total force on the group of atoms.

17.127.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

</tr>
<tr>
<td>fix 1 all nve/sphere disc</td>
</tr>
<tr>
<td>fix 1 all nve/sphere update dipole/dlm</td>
</tr>
</tbody>
</table>

17.128.3 Description

Perform constant NVE integration to update position, velocity, and angular velocity for finite-size spherical particles in the group each timestep. V is volume; E is energy. This creates a system trajectory consistent with the microcanonical ensemble.

This fix differs from the fix nve command, which assumes point particles and only updates their position and velocity.

If the update keyword is used with the dipole value, then the orientation of the dipole moment of each particle is also updated during the time integration. This option should be used for models where a dipole moment is assigned to finite-size particles, e.g. spheroids via use of the atom_style hybrid sphere dipole command.

The default dipole orientation integrator can be changed to the Dullweber-Leimkuhler-McLachlan integration scheme (Dullweber) when using update with the value dipole/dlm. This integrator is symplectic and time-reversible, giving better energy conservation and allows slightly longer timesteps at only a small additional computational cost.

If the disc keyword is used, then each particle is treated as a 2d disc (circle) instead of as a sphere. This is only possible for 2d simulations, as defined by the dimension keyword. The only difference between discs and spheres in this context is their moment of inertia, as used in the time integration.
Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Accelerator packages} page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \texttt{-suffix} command-line switch when you invoke LAMMPS, or you can use the \texttt{suffix} command in your input script. See the \textit{Accelerator packages} page for more instructions on how to use the accelerated styles effectively.

### 17.128.4 Restart, \texttt{fix\_modify}, output, run start/stop, minimize info

No information about this fix is written to \textit{binary restart files}. None of the \texttt{fix\_modify} options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various \textit{output commands}. No parameter of this fix can be used with the \texttt{start/stop} keywords of the \texttt{run} command. This fix is not invoked during \textit{energy minimization}.

### 17.128.5 Restrictions

This fix requires that atoms store torque and angular velocity (omega) and a radius as defined by the \texttt{atom\_style sphere} command. If the \texttt{dipole} keyword is used, then they must also store a dipole moment as defined by the \texttt{atom\_style dipole} command.

All particles in the group must be finite-size spheres. They cannot be point particles.

Use of the \texttt{disc} keyword is only allowed for 2d simulations, as defined by the \texttt{dimension} keyword.

### 17.129 \texttt{fix nve/spin} command

#### 17.129.1 Syntax

\texttt{fix ID group-ID nve/spin keyword values}

- \texttt{ID, group-ID} are documented in \texttt{fix} command
- \texttt{nve/spin} = style name of this fix command
• keyword = lattice

  lattice value = moving or frozen
  moving = integrate both spin and atomic degrees of freedom
  frozen = integrate spins on a fixed lattice

17.129.2 Examples

```
fix 3 all nve/spin lattice moving
fix 1 all nve/spin lattice frozen
```

17.129.3 Description

Perform a symplectic integration for the spin or spin-lattice system.

The lattice keyword defines if the spins are integrated on a lattice of fixed atoms (lattice = frozen), or if atoms are moving (lattice = moving). The first case corresponds to a spin dynamics calculation, and the second to a spin-lattice calculation. By default a spin-lattice integration is performed (lattice = moving).

The nve/spin fix applies a Suzuki-Trotter decomposition to the equations of motion of the spin lattice system, following the scheme:

```
\[ \begin{align*}
  v &\leftarrow v + L_v \cdot \Delta t / 2 \\
  s &\leftarrow s + L_s \cdot \Delta t / 2 \\
  r &\leftarrow r + L_r \cdot \Delta t \\
  s &\leftarrow s + L_s \cdot \Delta t / 2 \\
  v &\leftarrow v + L_v \cdot \Delta t / 2 \\
  s_0 &\leftarrow s_0 + L_{s_0} \cdot \Delta t / 4 \\
  s_{N-1} &\leftarrow s_{N-1} + L_{s_{N-1}} \cdot \Delta t / 4 \\
  s_N &\leftarrow s_N + L_{s_N} \cdot \Delta t / 2 \\
  s_{N-1} &\leftarrow s_{N-1} + L_{s_{N-1}} \cdot \Delta t / 4 \\
  s_0 &\leftarrow s_0 + L_{s_0} \cdot \Delta t / 4
\end{align*} \]
```

according to the implementation reported in (Omelyan).

A sectoring method enables this scheme for parallel calculations. The implementation of this sectoring algorithm is reported in (Tranchida).
17.129.4 Restrictions

This fix style can only be used if LAMMPS was built with the SPIN package. See the Build package page for more info.

To use the spin algorithm, it is necessary to define a map with the atom_modify command. Typically, by adding the command:

\[ \text{atom_modify map array} \]

before you create the simulation box. Note that the keyword “hash” instead of “array” is also valid.

17.129.5 Related commands

- ID, group-ID are documented in fix command
- nve/tri = style name of this fix command

17.130.2 Examples

\[ \text{fix 1 all nve/tri} \]

17.130.3 Description

Perform constant NVE integration to update position, velocity, orientation, and angular momentum for triangular particles in the group each timestep. V is volume; E is energy. This creates a system trajectory consistent with the microcanonical ensemble. See the Howto spherical page for an overview of using triangular particles.

This fix differs from the fix nve command, which assumes point particles and only updates their position and velocity.
17.130.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.130.5 Restrictions

This fix is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This fix requires that particles be triangles as defined by the atom_style tri command.

17.130.6 Related commands

17.131.1 Syntax

fix ID group-ID nvk

- ID, group-ID are documented in fix command
- nvk = style name of this fix command

17.131.2 Examples

fix 1 all nvk

17.131.3 Description

Perform constant kinetic energy integration using the Gaussian thermostat to update position and velocity for atoms in the group each timestep. V is volume; K is kinetic energy. This creates a system trajectory consistent with the isokinetic ensemble.

The equations of motion used are those of Minary et al in (Minary), a variant of those initially given by Zhang in (Zhang).

The kinetic energy will be held constant at its value given when fix nvk is initiated. If a different kinetic energy is desired, the velocity command should be used to change the kinetic energy prior to this fix.
17.131.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.131.5 Restrictions

The Gaussian thermostat only works when it is applied to all atoms in the simulation box. Therefore, the group must be set to all.

This fix has not yet been implemented to work with the RESPA integrator.

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

17.131.6 Related commands

none

17.131.7 Default

none

17.132 fix nvt/asphere command

Accelerator Variants: nvt/asphere/omp

17.132.1 Syntax

| fix ID group-ID nvt/asphere keyword value ...

- ID, group-ID are documented in fix command
- nvt/asphere = style name of this fix command
- additional thermostat related keyword/value pairs from the fix nvt command can be appended
17.132.2 Examples

```
fix 1 all nvt/asphere temp 300.0 300.0 100.0
fix 1 all nvt/asphere temp 300.0 300.0 100.0 drag 0.2
```

17.132.3 Description

Perform constant NVT integration to update position, velocity, orientation, and angular velocity each timestep for aspherical or ellipsoidal particles in the group using a Nose/Hoover temperature thermostat. V is volume; T is temperature. This creates a system trajectory consistent with the canonical ensemble.

This fix differs from the `fix nvt` command, which assumes point particles and only updates their position and velocity.

The thermostat is applied to both the translational and rotational degrees of freedom for the aspherical particles, assuming a compute is used which calculates a temperature that includes the rotational degrees of freedom (see below). The translational degrees of freedom can also have a bias velocity removed from them before thermostatting takes place; see the description below.

Additional parameters affecting the thermostat are specified by keywords and values documented with the `fix nvt` command. See, for example, discussion of the `temp` and `drag` keywords.

This fix computes a temperature each timestep. To do this, the fix creates its own compute of style “temp/asphere”, as if this command had been issued:

```
compute fix-ID_temp group-ID temp/asphere
```

See the `compute temp/asphere` command for details. Note that the ID of the new compute is the fix-ID + underscore + “temp”, and the group for the new compute is the same as the fix group.

Note that this is NOT the compute used by thermodynamic output (see the `thermo_style` command) with ID = `thermo_temp`. This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via the `compute_modify` command or print this temperature during thermodynamic output via the `thermo_style custom` command using the appropriate compute-ID. It also means that changing attributes of `thermo_temp` will have no effect on this fix.

Like other fixes that perform thermostatting, this fix can be used with `compute commands` that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial `region`, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the `fix modify` command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual `compute temp commands` to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Accelerator packages` page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Accelerator packages` page for more instructions on how to use the accelerated styles effectively.
17.132.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify temp option is supported by this fix. You can use it to assign a compute you have defined to this fix which will be used in its thermostatting procedure.

The cumulative energy change in the system imposed by this fix is included in the thermodynamic output keywords ecouple and econserve. See the thermo_style doc page for details.

This fix computes the same global scalar and global vector of quantities as does the fix nvt command.

This fix can ramp its target temperature over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

17.132.5 Restrictions

This fix is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This fix requires that atoms store torque and angular momentum and a quaternion as defined by the atom_style ellipsoid command.

All particles in the group must be finite-size. They cannot be point particles, but they can be aspherical or spherical as defined by their shape attribute.

17.133 fix nvt/body command

17.133.1 Syntax

| fix ID group-ID nvt/body keyword value ... |

- ID, group-ID are documented in fix command
- nvt/body = style name of this fix command
- additional thermostat related keyword/value pairs from the fix nvt command can be appended
17.133.2 Examples

\begin{verbatim}
  fix 1 all nvt/body temp 300.0 300.0 100.0
  fix 1 all nvt/body temp 300.0 300.0 100.0 drag 0.2
\end{verbatim}

17.133.3 Description

Perform constant NVT integration to update position, velocity, orientation, and angular velocity each timestep for body particles in the group using a Nose/Hoover temperature thermostat. \( V \) is volume; \( T \) is temperature. This creates a system trajectory consistent with the canonical ensemble.

This fix differs from the \texttt{fix nvt} command, which assumes point particles and only updates their position and velocity.

The thermostat is applied to both the translational and rotational degrees of freedom for the body particles, assuming a compute is used which calculates a temperature that includes the rotational degrees of freedom (see below). The translational degrees of freedom can also have a bias velocity removed from them before thermostatting takes place; see the description below.

Additional parameters affecting the thermostat are specified by keywords and values documented with the \texttt{fix nvt} command. See, for example, discussion of the \texttt{temp} and \texttt{drag} keywords.

This fix computes a temperature each timestep. To do this, the fix creates its own compute of style “temp/body”, as if this command had been issued:

\begin{verbatim}
compute fix-ID_temp group-ID temp/body
\end{verbatim}

See the \texttt{compute temp/body} command for details. Note that the ID of the new compute is the fix-ID + underscore + “temp”, and the group for the new compute is the same as the fix group.

Note that this is NOT the compute used by thermodynamic output (see the \texttt{thermo_style} command) with ID = \texttt{thermo_temp}. This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via the \texttt{compute_modify} command or print this temperature during thermodynamic output via the \texttt{thermo_style custom} command using the appropriate compute-ID. It also means that changing attributes of \texttt{thermo_temp} will have no effect on this fix.

Like other fixes that perform thermostatting, this fix can be used with \texttt{compute commands} that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial \texttt{region}, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the \texttt{fix_modify} command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual \texttt{compute temp commands} to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \texttt{Accelerator packages} page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \texttt{Build package} page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \texttt{-suffix command-line switch} when you invoke LAMMPS, or you can use the \texttt{suffix} command in your input script.

See the \texttt{Accelerator packages} page for more instructions on how to use the accelerated styles effectively.
17.133.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify temp option is supported by this fix. You can use it to assign a compute you have defined to this fix which will be used in its thermostatting procedure.

The cumulative energy change in the system imposed by this fix is included in the thermodynamic output keywords ecouple and econserve. See the thermo_style doc page for details.

This fix computes the same global scalar and global vector of quantities as does the fix nvt command.

This fix can ramp its target temperature over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

17.133.5 Restrictions

This fix is part of the BODY package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This fix requires that atoms store torque and angular momentum and a quaternion as defined by the atom_style body command.

```

17.134.3 Description

This fix combines the RATTLE-based (Andersen) time integrator of fix nve/manifold/rattle (Paquay) with a Nose-Hoover-chain thermostat to sample the canonical ensemble of particles constrained to a curved surface (manifold). This sampling does suffer from discretization bias of O(dt). For a list of currently supported manifolds and their parameters, see the Howto manifold doc page.

17.134.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.134.5 Restrictions

This fix is part of the MANIFOLD package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

17.134.6 Related commands

```

- ID, group-ID are documented in fix command
- nvt/sllod = style name of this fix command
- additional thermostat related keyword/value pairs from the fix nvt command can be appended

17.135.2 Examples

```
fix 1 all nvt/sllod temp 300.0 300.0 100.0
fix 1 all nvt/sllod temp 300.0 300.0 100.0 drag 0.2
```

17.135.3 Description

Perform constant NVT integration to update positions and velocities each timestep for atoms in the group using a Nose/Hoover temperature thermostat. \( V \) is volume; \( T \) is temperature. This creates a system trajectory consistent with the canonical ensemble.

This thermostat is used for a simulation box that is changing size and/or shape, for example in a non-equilibrium MD (NEMD) simulation. The size/shape change is induced by use of the fix deform command, so each point in the simulation box can be thought of as having a “streaming” velocity. This position-dependent streaming velocity is subtracted from each atom’s actual velocity to yield a thermal velocity which is used for temperature computation and thermostatting. For example, if the box is being sheared in x, relative to y, then points at the bottom of the box (low y) have a small x velocity, while points at the top of the box (hi y) have a large x velocity. These velocities do not contribute to the thermal “temperature” of the atom.

Note: Fix deform has an option for remapping either atom coordinates or velocities to the changing simulation box. To use fix nvt/sllod, fix deform should NOT remap atom positions, because fix nvt/sllod adjusts the atom positions and velocities to create a velocity profile that matches the changing box size/shape. Fix deform SHOULD remap atom velocities when atoms cross periodic boundaries since that is consistent with maintaining the velocity profile created by fix nvt/sllod. LAMMPS will give an error if this setting is not consistent.

The SLLOD equations of motion, originally proposed by Hoover and Ladd (see (Evans and Morriss)), were proven to be equivalent to Newton’s equations of motion for shear flow by (Evans and Morriss). They were later shown to generate the desired velocity gradient and the correct production of work by stresses for all forms of homogeneous flow by (Daivis and Todd). The LAMMPS implementation corresponds to the p-SLLOD variant of SLLOD. (Edwards). The equations of motion are coupled to a Nose/Hoover chain thermostat in a velocity Verlet formulation, closely following the implementation used for the fix nvt command.

Note: A recent (2017) book by (Daivis and Todd) discusses use of the SLLOD method and non-equilibrium MD (NEMD) thermostatting generally, for both simple and complex fluids, e.g. molecular systems. The latter can be tricky to do correctly.
Additional parameters affecting the thermostat are specified by keywords and values documented with the `fix nvt` command. See, for example, discussion of the `temp` and `drag` keywords.

This fix computes a temperature each timestep. To do this, the fix creates its own compute of style “temp/deform”, as if this command had been issued:

```
compute fix-ID_temp group-ID temp/deform
```

See the `compute temp/deform` command for details. Note that the ID of the new compute is the fix-ID + underscore + “temp”, and the group for the new compute is the same as the fix group.

Note that this is NOT the compute used by thermodynamic output (see the `thermo_style` command) with ID = `thermo_temp`. This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via the `compute_modify` command or print this temperature during thermodynamic output via the `thermo_style custom` command using the appropriate compute-ID. It also means that changing attributes of `thermo_temp` will have no effect on this fix.

Like other fixes that perform thermostatising, this fix can be used with `compute` commands that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial `region`, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the `fix_modify` command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual `compute temp` commands to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Accelerator packages` page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Accelerator packages` page for more instructions on how to use the accelerated styles effectively.

### 17.135.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat to binary restart files. See the `read_restart` command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The `fix_modify temp` option is supported by this fix. You can use it to assign a `compute` you have defined to this fix which will be used in its thermostating procedure.

The cumulative energy change in the system imposed by this fix is included in the thermodynamic output keywords `ecouple` and `econserve`. See the `thermo_style` doc page for details.

This fix computes the same global scalar and global vector of quantities as does the `fix nvt` command.

This fix can ramp its target temperature over multiple runs, using the `start` and `stop` keywords of the `run` command. See the `run` command for details of how to do this.

This fix is not invoked during energy minimization.
17.135.5 Restrictions

This fix works best without Nose-Hoover chain thermostats, i.e. using tchain = 1. Setting tchain to larger values can result in poor equilibration.

17.135.6 Related commands

fix nve, fix nvt, fix temp/rescale, fix langevin, fix_modify, compute temp/deform

17.135.7 Default

Same as fix nvt, except tchain = 1.

17.136.1 Syntax

fix ID group-ID nvt/sllod/eff keyword value ...

- ID, group-ID are documented in fix command
- nvt/sllod/eff = style name of this fix command
- additional thermostat related keyword/value pairs from the fix nvt/eff command can be appended

17.136.2 Examples

fix 1 all nvt/sllod/eff temp 300.0 300.0 0.1
fix 1 all nvt/sllod/eff temp 300.0 300.0 0.1 drag 0.2

17.136.3 Description

Perform constant NVT integration to update positions and velocities each timestep for nuclei and electrons in the group for the electron force field model, using a Nose-Hoover temperature thermostat. V is volume; T is temperature. This creates a system trajectory consistent with the canonical ensemble.

The operation of this fix is exactly like that described by the fix nvt/sllod command, except that the radius and radial velocity of electrons are also updated and thermostatted. Likewise the temperature calculated by the fix, using the compute it creates (as discussed in the fix nvt, npt, and nph doc page), is performed with a compute temp/deform/eff command that includes the eFF contribution to the temperature from the electron radial velocity.
17.136.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify temp option is supported by this fix. You can use it to assign a compute you have defined to this fix which will be used in its thermostatting procedure.

The cumulative energy change in the system imposed by this fix is included in the thermodynamic output keywords ecouple and econserve. See the thermo_style doc page for details.

This fix computes the same global scalar and global vector of quantities as does the fix nvt/eff command.

This fix can ramp its target temperature over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

17.136.5 Restrictions

This fix is part of the EFF package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This fix works best without Nose-Hoover chain thermostats, i.e. using tchain = 1. Setting tchain to larger values can result in poor equilibration.

17.136.6 Related commands

fix nve/eff, fix nvt/eff, fix langevin/eff, fix nvt/sllod, fix_modify, compute temp/deform/eff

17.136.7 Default

Same as fix nvt/eff, except tchain = 1.

17.137 fix nvt/sphere command

Accelerator Variants: nvt/sphere/omp

17.137.1 Syntax

fix ID group-ID nvt/sphere keyword value ...

- ID, group-ID are documented in fix command
- nvt/sphere = style name of this fix command
- zero or more keyword/value pairs may be appended
- keyword = disc

17.137. fix nvt/sphere command 1431
disc value = none = treat particles as 2d discs, not spheres

- additional thermostat related keyword/value pairs from the fix nvt command can be appended

### 17.137.2 Examples

```
fix 1 all nvt/sphere temp 300.0 300.0 100.0
fix 1 all nvt/sphere temp 300.0 300.0 100.0 disc
fix 1 all nvt/sphere temp 300.0 300.0 100.0 drag 0.2
```

### 17.137.3 Description

Perform constant NVT integration to update position, velocity, and angular velocity each timestep for finite-size spherical particles in the group using a Nose/Hoover temperature thermostat. V is volume; T is temperature. This creates a system trajectory consistent with the canonical ensemble.

This fix differs from the fix nvt command, which assumes point particles and only updates their position and velocity.

The thermostat is applied to both the translational and rotational degrees of freedom for the spherical particles, assuming a compute is used which calculates a temperature that includes the rotational degrees of freedom (see below). The translational degrees of freedom can also have a bias velocity removed from them before thermostatting takes place; see the description below.

If the disc keyword is used, then each particle is treated as a 2d disc (circle) instead of as a sphere. This is only possible for 2d simulations, as defined by the dimension keyword. The only difference between discs and spheres in this context is their moment of inertia, as used in the time integration.

Additional parameters affecting the thermostat are specified by keywords and values documented with the fix nvt command. See, for example, discussion of the temp and drag keywords.

This fix computes a temperature each timestep. To do this, the fix creates its own compute of style “temp/sphere”, as if this command had been issued:

```
compute fix-ID_temp group-ID temp/sphere
```

See the compute temp/sphere command for details. Note that the ID of the new compute is the fix-ID + underscore + “temp”, and the group for the new compute is the same as the fix group.

Note that this is NOT the compute used by thermodynamic output (see the thermo_style command) with ID = thermo_temp. This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via the compute_modify command or print this temperature during thermodynamic output via the thermo_style custom command using the appropriate compute-ID. It also means that changing attributes of thermo_temp will have no effect on this fix.

Like other fixes that perform thermostatting, this fix can be used with compute commands that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial region, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the fix_modify command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual compute temp commands to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

---

styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the accelerator packages
The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

17.137.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the Nose/Hoover thermostat to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify temp option is supported by this fix. You can use it to assign a compute you have defined to this fix which will be used in its thermostatting procedure.

The cumulative energy change in the system imposed by this fix is included in the thermodynamic output keywords ecouple and econserve. See the thermo_style doc page for details.

This fix computes the same global scalar and global vector of quantities as does the fix nvt command.

This fix can ramp its target temperature over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

17.137.5 Restrictions

This fix requires that atoms store torque and angular velocity (omega) and a radius as defined by the atom_style sphere command.

All particles in the group must be finite-size spheres. They cannot be point particles.

Use of the disc keyword is only allowed for 2d simulations, as defined by the dimension keyword.

```
fix ID group-ID oneway N region-ID direction
```

- ID, group-ID are documented in `fix` command
- oneway = style name of this fix command
- N = apply this fix every this many timesteps
- region-ID = ID of region where fix is active
- direction = x or -x or y or -y or z or -z = coordinate and direction of the oneway constraint

17.138.2 Examples

```
fix ions oneway 10 semi -x
fix all oneway 1 left -z
fix all oneway 1 right z
```

17.138.3 Description

Enforce that particles in the group and in a given region can only move in one direction. This is done by reversing a particle’s velocity component, if it has the wrong sign in the specified dimension. The effect is that the particle moves in one direction only.

This can be used, for example, as a simple model of a semi-permeable membrane, or as an implementation of Maxwell’s demon.

17.138.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.138.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

fix gb all orient/bcc 0 1 2.882 0.001 0.25 0.75 ngb.left ngb.right
```

17.140.3 Description

The fix applies an orientation-dependent force to atoms near a planar grain boundary which can be used to induce grain boundary migration (in the direction perpendicular to the grain boundary plane). The motivation and explanation of this force and its application are described in (Janssens). The adaptation to bcc crystals is described in (Wicaksono1).

The computed force is only applied to atoms in the fix group.

The basic idea is that atoms in one grain (on one side of the boundary) have a potential energy dE added to them. Atoms in the other grain have 0.0 potential energy added. Atoms near the boundary (whose neighbor environment is intermediate between the two grain orientations) have an energy between 0.0 and dE added. This creates an effective driving force to reduce the potential energy of atoms near the boundary by pushing them towards one of the grain orientations. For dir = 1 and dE > 0, the boundary will thus move so that the grain described by file0 grows and the grain described by file1 shrinks. Thus this fix is designed for simulations of two-grain systems, either with one grain boundary and free surfaces parallel to the boundary, or a system with periodic boundary conditions and two equal and...
opposite grain boundaries. In either case, the entire system can displace during the simulation, and such motion should be accounted for in measuring the grain boundary velocity.

The potential energy added to atom $I$ is given by these formulas

$$\xi_i = \sum_{j=1}^{12} |r_{ij} - r_{ij}^I|$$  \hspace{1cm} (1)

$$\xi_{IJ} = \sum_{j=1}^{12} |r_{ij}^J - r_{ij}^I|$$  \hspace{1cm} (2)

$$\xi_{low} = cutlo \xi_{IJ}$$  \hspace{1cm} (3)

$$\xi_{high} = cuthi \xi_{IJ}$$  \hspace{1cm} (4)

$$\omega_i = \frac{\pi}{2} \frac{\xi_i - \xi_{low}}{\xi_{high} - \xi_{low}}$$  \hspace{1cm} (5)

$$u_i = 0 \quad \text{for} \quad \xi_i < \xi_{low}$$

$$= dE \frac{1 - \cos(2\omega_i)}{2} \quad \text{for} \quad \xi_{low} < \xi_i < \xi_{high}$$  \hspace{1cm} (6)

$$= dE \quad \text{for} \quad \xi_{high} < \xi_i$$

which are fully explained in (Janssens). For fcc crystals this order parameter $X_i$ for atom $I$ in equation (1) is a sum over the 12 nearest neighbors of atom $I$. For bcc crystals it is the corresponding sum of the 8 nearest neighbors. $R_j$ is the vector from atom $I$ to its neighbor $J$, and $RI_j$ is a vector in the reference (perfect) crystal. That is, if $dir = 0/1$, then $RI_j$ is a vector to an atom coord from file 0/1. Equation (2) gives the expected value of the order parameter $X_{ij}$ in the other grain. hi and lo cutoffs are defined in equations (3) and (4), using the input parameters $cutlo$ and $cuthi$ as thresholds to avoid adding grain boundary energy when the deviation in the order parameter from 0 or 1 is small (e.g. due to thermal fluctuations in a perfect crystal). The added potential energy $U_i$ for atom $I$ is given in equation (6) where it is interpolated between 0 and $dE$ using the two threshold $X_i$ values and the $W_i$ value of equation (5).

The derivative of this energy expression gives the force on each atom which thus depends on the orientation of its neighbors relative to the 2 grain orientations. Only atoms near the grain boundary feel a net force which tends to drive them to one of the two grain orientations.

In equation (1), the reference vector used for each neighbor is the reference vector closest to the actual neighbor position. This means it is possible two different neighbors will use the same reference vector. In such cases, the atom in question is far from a perfect orientation and will likely receive the full $dE$ addition, so the effect of duplicate reference vector usage is small.

The $dir$ parameter determines which grain wants to grow at the expense of the other. A value of 0 means the first grain will shrink; a value of 1 means it will grow. This assumes that $dE$ is positive. The reverse will be true if $dE$ is negative.

The $alat$ parameter is the cubic lattice constant for the fcc or bcc material and is only used to compute a cutoff distance of $1.57 * alat / \sqrt{2}$ for finding the 12 or 8 nearest neighbors of each atom (which should be valid for an fcc or bcc crystal). A longer/shorter cutoff can be imposed by adjusting $alat$. If a particular atom has less than 12 or 8 neighbors within the cutoff, the order parameter of equation (1) is effectively multiplied by 12 or 8 divided by the actual number of neighbors within the cutoff.

The $dE$ parameter is the maximum amount of additional energy added to each atom in the grain which wants to shrink.

The $cutlo$ and $cuthi$ parameters are used to reduce the force added to bulk atoms in each grain far away from the boundary. An atom in the bulk surrounded by neighbors at the ideal grain orientation would compute an order parameter of 0 or 1 and have no force added. However, thermal vibrations in the solid will cause the order parameters to be greater
than 0 or less than 1. The cutoff parameters mask this effect, allowing forces to only be added to atoms with order-
parameters between the cutoff values.

*File0* and *file1* are filenames for the two grains which each contain 6 vectors (6 lines with 3 values per line) which
specify the grain orientations. Each vector is a displacement from a central atom (0,0,0) to a nearest neighbor atom in
an fcc lattice at the proper orientation. The vector lengths should all be identical since an fcc lattice has a coordination
number of 12. Only 6 are listed due to symmetry, so the list must include one from each pair of equal-and-opposite
neighbors. A pair of orientation files for a Sigma=5 tilt boundary are shown below. A tutorial that can help for writing
the orientation files is given in *(Wicaksono2)*

### 17.140.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix_modify energy* option is supported by this fix to add the potential energy of atom interactions with the grain
boundary driving force to the global potential energy of the system as part of *thermodynamic output*. The default
setting for this fix is *fix_modify energy no*.

The *fix_modify respa* option is supported by these fixes. This allows to set at which level of the *r-RESPA* integrator a
fix is adding its forces. Default is the outermost level.

This fix calculates a global scalar which can be accessed by various *output commands*. The scalar is the potential
energy change due to this fix. The scalar value calculated by this fix is “extensive”.

This fix also calculates a per-atom array which can be accessed by various *output commands*. The array stores the
order parameter Xi and normalized order parameter (0 to 1) for each atom. The per-atom values can be accessed on
any timestep.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

This fix is not invoked during *energy minimization*.

### 17.140.5 Restrictions

These fixes are part of the ORIENT package. They are only enabled if LAMMPS was built with that package. See the
*Build package* page for more info.

These fixes should only be used with fcc or bcc lattices.

### 17.140.6 Related commands

*fix_modify*

### 17.140.7 Default

none

For illustration purposes, here are example files that specify a Sigma=5 \langle 100 \rangle tilt boundary. This is for a lattice constant of 3.5706 Angs.

17.141 fix orient/eco command

fix ID group-ID orient/eco u0 eta cutoff orientationsFile

- ID, group-ID are documented in fix command
- u0 = energy added to each atom (energy units)
- eta = cutoff value (usually 0.25)
- cutoff = cutoff radius for orientation parameter calculation
- orientationsFile = file that specifies orientation of each grain

17.141.1 Examples

fix gb all orient/eco 0.08 0.25 3.524 sigma5.ori

17.141.2 Description

The fix applies a synthetic driving force to a grain boundary which can be used for the investigation of grain boundary motion. The affiliation of atoms to either of the two grains forming the grain boundary is determined from an orientation-dependent order parameter as described in (Ulomek). The potential energy of atoms is either increased by an amount of 0.5*\(u0\) or -0.5*\(u0\) according to the orientation of the surrounding crystal. This creates a potential energy gradient which pushes atoms near the grain boundary to orient according to the energetically favorable grain orientation. This fix is designed for applications in bicrystal system with one grain boundary and open ends, or two opposite grain boundaries in a periodic system. In either case, the entire system can experience a displacement during the simulation which needs to be accounted for in the evaluation of the grain boundary velocity. While the basic method is described in (Ulomek), the implementation follows the efficient implementation from (Schratt & Mohles).
The synthetic potential energy added to an atom $j$ is given by the following formulas:

$$w(|\vec{r}_{jk}|) = w_{jk} = \begin{cases} \frac{|\vec{r}_{jk}|^4}{r_{\text{cut}}^4} - 2 \frac{|\vec{r}_{jk}|^2}{r_{\text{cut}}^2} + 1, & |\vec{r}_{jk}| < r_{\text{cut}} \\ 0, & |\vec{r}_{jk}| \geq r_{\text{cut}} \end{cases}$$

$$\chi_j = \frac{1}{N} \sum_{l=1}^{3} \left[ |\psi^I_l(\vec{r}_j)|^2 - |\psi^{II}_l(\vec{r}_j)|^2 \right]$$

$$\psi^X_l(\vec{r}_j) = \sum_{k \in \Gamma_j} w_{jk} \exp \left(i \vec{r}_{jk} \cdot \vec{q}_X^l\right)$$

$$u(\chi_j) = \frac{u_0}{2} \begin{cases} 1, & \chi_j \geq \eta \\ \sin \left(\frac{\pi \chi_j}{2\eta}\right), & -\eta < \chi_j < \eta \\ -1, & \chi_j \leq -\eta \end{cases}$$

which are fully explained in (Ulomek) and (Schratt & Mohles).

The force on each atom is the negative gradient of the synthetic potential energy. It depends on the surrounding of this atom. An atom far from the grain boundary does not experience a synthetic force as its surrounding is that of an oriented single crystal and thermal fluctuations are masked by the parameter $\eta$. Near the grain boundary however, the gradient is nonzero and synthetic force terms are computed. The orientationsFile specifies the perfect oriented crystal basis vectors for the two adjoining crystals. The first three lines (line=row vector) for the energetically penalized and the last three lines for the energetically favored grain assuming $u_0$ is positive. For negative $u_0$, this is reversed. With the cutoff parameter, the size of the region around each atom which is used in the order parameter computation is defined. The cutoff must be smaller than the interaction range of the MD potential. It should at least include the nearest neighbor shell. For high temperatures or low angle grain boundaries, it might be beneficial to increase the cutoff in order to get a more precise identification of the atoms surrounding. However, computation time will increase as more atoms are considered in the order parameter and force computation. It is also worth noting that the cutoff radius must not exceed the communication distance for ghost atoms in LAMMPS. With orientationsFile, the 6 oriented crystal basis vectors is specified. Each line of the input file contains the three components of a primitive lattice vector oriented according to the grain orientation in the simulation box. The first (last) three lines correspond to the primitive lattice vectors of the first (second) grain. An example for a $\Sigma \langle 001 \rangle$ mis-orientation is given at the end.

If no synthetic energy difference between the grains is created, $u_0 = 0$, the force computation is omitted. In this case, still, the order parameter of the driving force is computed and can be used to track the grain boundary motion throughout the simulation.

### 17.141.3 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to :doc: binary restart files <restart>.

The fix_modify energy option is supported by this fix to add the potential energy of atom interactions with the grain boundary driving force to the global potential energy of the system as part of thermodynamic output. The default setting for this fix is fix_modify energy no.

This fix calculates a per-atom array with 2 columns, which can be accessed by indices 1-1 by any command that uses per-atom values from a fix as input. See the Howto output doc page for an overview of LAMMPS output options.

The first column is the order parameter for each atom; the second is the thermal masking value for each atom. Both are described above.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.
17.141.4 Restrictions

This fix is part of the ORIENT package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

17.142 fix pafi command

17.142.1 Syntax

```
fix ID group-ID pafi compute-ID Temp Tdamp seed keyword values...
```

- ID, group-ID are documented in fix command
- pafi = style name of this fix command
- compute-ID = ID of a compute property/atom that holds data used by this fix
- Temp = desired temperature (temperature units)
- Tdamp = damping parameter (time units)
- seed = random number seed to use for white noise (positive integer)
- keyword = overdamped or com
overdamped value = yes or no or 1 or 0
  yes or 1 = Brownian (overdamped) integration in hyperplane
  no or 0 = Langevin integration in hyperplane
com value = yes or no or 1 or 0
  yes or 1 = zero linear momentum, fixing center or mass (recommended)
  no or 0 = do not zero linear momentum, allowing center of mass drift

17.142.2 Examples

```
compute pa all property/atom d_nx d_ny d_nz d_dnx d_dny d_ddnz
run 0 post no
fix hp all pafi pa 500.0 0.01 434 overdamped yes
```

17.142.3 Description

Perform Brownian or Langevin integration whilst constraining the system to lie in some hyperplane, which is expected to be the tangent plane to some reference pathway in a solid state system. The instantaneous value of a modified force projection is also calculated, whose time integral can be shown to be equal to the true free energy gradient along the minimum free energy path local to the reference pathway. A detailed discussion of the projection technique can be found in (Swinburne).

This fix can be used with LAMMPS as demonstrated in examples/PACKAGES/pafi, though it is primarily intended to be coupled with the PAFI C++ code, developed at https://github.com/tomswinburne/pafi, which distributes multiple LAMMPS workers in parallel to compute and collate hyperplane-constrained averages, allowing the calculation of free energy barriers and pathways.

A compute property/atom must be provided with 9 fields per atom coordinate, which in order are the x,y,z coordinates of a configuration on the reference path, the x,y,z coordinates of the path tangent (derivative of path position with path coordinate) and the x,y,z coordinates of the change in tangent (derivative of path tangent with path coordinate).

A 4-element vector is also calculated by this fix. The 4 components are the modified projected force, its square, the expected projection of the minimum free energy path tangent on the reference path tangent and the minimum image distance between the current configuration and the reference configuration, projected along the path tangent. This latter value should be essentially zero.

Note: When com=yes/1, which is recommended, the provided tangent vector must also have zero center of mass. This can be achieved by subtracting from each coordinate of the path tangent the average x,y,z value. The PAFI C++ code (see above) can generate these paths for use in LAMMPS.

Note: When overdamped=yes/1, the Tdamp parameter should be around 5-10 times smaller than that used in typical Langevin integration. See fix langevin for typical values.
17.142.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. This fix produces a global vector each timestep which can be accessed by various output commands.

17.142.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

17.142.6 Default

The option defaults are com = yes, overdamped = no

17.143.3 Description

Calculate the dynamical matrix from molecular dynamics simulations based on fluctuation-dissipation theory for a group of atoms.

Consider a crystal with \( N \) unit cells in three dimensions labeled \( l = (l_1, l_2, l_3) \) where \( l_i \) are integers. Each unit cell is defined by three linearly independent vectors \( \mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_3 \) forming a parallelepiped, containing \( K \) basis atoms labeled \( k \).

Based on fluctuation-dissipation theory, the force constant coefficients of the system in reciprocal space are given by (Campana, Kong)

\[
\Phi_{k\alpha,k'\beta}(q) = k_B T G_{k\alpha,k'\beta}^{-1}(q)
\]

where \( G \) is the Green’s functions coefficients given by

\[
G_{k\alpha,k'\beta}(q) = \langle \mathbf{u}_{k\alpha}(q) \cdot \mathbf{u}_{k'\beta}^*(q) \rangle
\]

where \( \langle \ldots \rangle \) denotes the ensemble average, and

\[
\mathbf{u}_{k\alpha}(q) = \sum_l \mathbf{u}_{lk\alpha} \exp(iqr_l)
\]

is the \( \alpha \) component of the atomic displacement for the \( k \)th atom in the unit cell in reciprocal space at \( q \). In practice, the Green’s functions coefficients can also be measured according to the following formula,

\[
G_{k\alpha,k'\beta}(q) = \langle \mathbf{R}_{k\alpha}(q) \cdot \mathbf{R}_{k'\beta}^*(q) \rangle - \langle \mathbf{R}_{k\alpha}(q) \rangle \cdot \langle \mathbf{R}_{k'\beta}^*(q) \rangle
\]

where \( \mathbf{R} \) is the instantaneous positions of atoms, and \( \langle \mathbf{R} \rangle \) is the averaged atomic positions. It gives essentially the same results as the displacement method and is easier to implement in an MD code.

Once the force constant matrix is known, the dynamical matrix \( D \) can then be obtained by

\[
D_{k\alpha,k'\beta}(q) = (m_km_{k'})^{-\frac{1}{2}} \Phi_{k\alpha,k'\beta}(q)
\]

whose eigenvalues are exactly the phonon frequencies at \( q \).

This fix uses positions of atoms in the specified group and calculates two-point correlations. To achieve this, the positions of the atoms are examined every \( Nevery \) steps and are Fourier-transformed into reciprocal space, where the averaging process and correlation computation is then done. After every \( Noutput \) measurements, the matrix \( G(q) \) is calculated and inverted to obtain the elastic stiffness coefficients. The dynamical matrices are then constructed and written to \( prefix.bin.timestep \) files in binary format and to the file \( prefix.log \) for each wave-vector \( q \).

A detailed description of this method can be found in (Kong2011).

The \( sysdim \) keyword is optional. If specified with a value smaller than the dimensionality of the LAMMPS simulation, its value is used for the dynamical matrix calculation. For example, using LAMMPS to model a 2D or 3D system, the phonon dispersion of a 1D atomic chain can be computed using \( sysdim = 1 \).

The \( nasr \) keyword is optional. An iterative procedure is employed to enforce the acoustic sum rule on \( \Phi \) at \( \Gamma \), and the number provided by keyword \( nasr \) gives the total number of iterations. For a system whose unit cell has only one atom, \( nasr = 1 \) is sufficient; for other systems, \( nasr = 10 \) is typically sufficient.
The *map_file* contains the mapping information between the lattice indices and the atom IDs, which tells the code which atom sits at which lattice point; the lattice indices start from 0. An auxiliary code, *latgen*, can be employed to generate the compatible map file for various crystals.

In case one simulates a non-periodic system, where the whole simulation box is treated as a unit cell, one can set *map_file* as GAMMA, so that the mapping info will be generated internally and a file is not needed. In this case, the dynamical matrix at only the gamma-point will/can be evaluated. Please keep in mind that fix-phonon is designed for crystals, it will be inefficient and even degrade the performance of lammps in case the unit cell is too large.

The calculated dynamical matrix elements are written out in energy/distance^2/mass units. The coordinates for \( q \) points in the log file is in the units of the basis vectors of the corresponding reciprocal lattice.

### 17.143.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*.

The *fix_modify temp* option is supported by this fix. You can use it to change the temperature compute from thermo_temp to the one that reflects the true temperature of atoms in the group.

No global scalar or vector or per-atom quantities are stored by this fix for access by various *output commands*.

Instead, this fix outputs its initialization information (including mapping information) and the calculated dynamical matrices to the file *prefix.log*, with the specified *prefix*. The dynamical matrices are also written to files *prefix.bin.timestep* in binary format. These can be read by the post-processing tool in tools/phonon to compute the phonon density of states and/or phonon dispersion curves.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command.

This fix is not invoked during *energy minimization*.

### 17.143.5 Restrictions

This fix assumes a crystalline system with periodical lattice. The temperature of the system should not exceed the melting temperature to keep the system in its solid state.

This fix is part of the PHONON package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This fix requires LAMMPS be built with an FFT library. See the *Build settings* page for details.

### 17.143.6 Related commands

*compute msd, dynamical_matrix*

### 17.143.7 Default

The option defaults are *sysdim =* the same dimension as specified by the *dimension* command, and *nasr = 20*.

17.144 fix pimd command

17.144.1 Syntax

```plaintext
fix ID group-ID pimd keyword value ...
```

- ID, group-ID are documented in `fix` command
- `pimd` = style name of this fix command
- zero or more keyword/value pairs may be appended
- `method = method` or `fmass = fmass` or `sp = sp` or `temp = temp` or `nhc = nhc`
  - `method` value = `pimd` or `nmpimd` or `cmd`
  - `fmass` value = scaling factor on mass
  - `sp` value = scaling factor on Planck constant
  - `temp` value = temperature (temperature units)
  - `nhc` value = $N_c = \text{number of chains in Nose-Hoover thermostat}$

17.144.2 Examples

```plaintext
fix 1 all pimd method nmpimd fmass 1.0 sp 2.0 temp 300.0 nhc 4
```

17.144.3 Description

This command performs quantum molecular dynamics simulations based on the Feynman path integral to include effects of tunneling and zero-point motion. In this formalism, the isomorphism of a quantum partition function for the original system to a classical partition function for a ring-polymer system is exploited, to efficiently sample configurations from the canonical ensemble (Feynman). The classical partition function and its components are given by the following equations:

\[
Z = \int dq dp \cdot \exp[-\beta H_{eff}]
\]

\[
H_{eff} = \left( \sum_{i=1}^{P} \frac{p_i^2}{2m_i} \right) + V_{eff}
\]

\[
V_{eff} = \sum_{i=1}^{P} \left[ \frac{mP}{2\beta^2\hbar^2}(q_i - q_{i+1})^2 + \frac{1}{P} V(q_i) \right]
\]

The interested user is referred to any of the numerous references on this methodology, but briefly, each quantum particle in a path integral simulation is represented by a ring-polymer of $P$ quasi-beads, labeled from 1 to $P$. During the simulation, each quasi-bead interacts with beads on the other ring-polymers with the same imaginary time index (the second term in the effective potential above). The quasi-beads also interact with the two neighboring quasi-beads through the spring potential in imaginary-time space (first term in effective potential). To sample the canonical ensemble, a Nose-Hoover massive chain thermostat is applied (Tuckerman). With the massive chain algorithm, a chain of NH thermostats
is coupled to each degree of freedom for each quasi-bead. The keyword `temp` sets the target temperature for the system and the keyword `nhc` sets the number $N_c$ of thermostats in each chain. For example, for a simulation of $N$ particles with $P$ beads in each ring-polymer, the total number of NH thermostats would be $3 \times N \times P \times N_c$.

**Note:** This fix implements a complete velocity-verlet integrator combined with NH massive chain thermostat, so no other time integration fix should be used.

The `method` keyword determines what style of PIMD is performed. A value of `pimd` is standard PIMD. A value of `nmpimd` is for normal-mode PIMD. A value of `cmd` is for centroid molecular dynamics (CMD). The difference between the styles is as follows.

In standard PIMD, the value used for a bead’s fictitious mass is arbitrary. A common choice is to use $M_i = m/P$, which results in the mass of the entire ring-polymer being equal to the real quantum particle. But it can be difficult to efficiently integrate the equations of motion for the stiff harmonic interactions in the ring polymers.

A useful way to resolve this issue is to integrate the equations of motion in a normal mode representation, using Normal Mode Path-Integral Molecular Dynamics (NMPIMD) (Cao1). In NMPIMD, the NH chains are attached to each normal mode of the ring-polymer and the fictitious mass of each mode is chosen as $M_k = \text{the eigenvalue of the Kth normal mode for } k > 0$. The $k = 0$ mode, referred to as the zero-frequency mode or centroid, corresponds to overall translation of the ring-polymer and is assigned the mass of the real particle.

Motion of the centroid can be effectively uncoupled from the other normal modes by scaling the fictitious masses to achieve a partial adiabatic separation. This is called a Centroid Molecular Dynamics (CMD) approximation (Cao2). The time-evolution (and resulting dynamics) of the quantum particles can be used to obtain centroid time correlation functions, which can be further used to obtain the true quantum correlation function for the original system. The CMD method also uses normal modes to evolve the system, except only the $k > 0$ modes are thermostatted, not the centroid degrees of freedom.

The keyword `fmass` sets a further scaling factor for the fictitious masses of beads, which can be used for the Partial Adiabatic CMD (Hone), or to be set as $P$, which results in the fictitious masses to be equal to the real particle masses.

The keyword `sp` is a scaling factor on Planck’s constant, which can be useful for debugging or other purposes. The default value of 1.0 is appropriate for most situations.

The PIMD algorithm in LAMMPS is implemented as a hyper-parallel scheme as described in (Calhoun). In LAMMPS this is done by using `multi-replica feature` in LAMMPS, where each quasi-particle system is stored and simulated on a separate partition of processors. The following diagram illustrates this approach. The original system with 2 ring polymers is shown in red. Since each ring has 4 quasi-beads (imaginary time slices), there are 4 replicas of the system, each running on one of the 4 partitions of processors. Each replica (shown in green) owns one quasi-bead in each ring.
To run a PIMD simulation with $M$ quasi-beads in each ring polymer using $N$ MPI tasks for each partition’s domain-decomposition, you would use $P = M \times N$ processors (cores) and run the simulation as follows:

```
mpirun -np P lmp_mpi -partition MxN -in script
```

Note that in the LAMMPS input script for a multi-partition simulation, it is often very useful to define a *uloop-style variable* such as

```
variable ibead uloop M pad
```

where $M$ is the number of quasi-beads (partitions) used in the calculation. The uloop variable can then be used to manage I/O related tasks for each of the partitions, e.g.

```
dump dcd all dcd 10 system_${ibead}.dcd
restart 1000 system_${ibead}.restart1 system_${ibead}.restart2
read_restart system_${ibead}.restart2
```
17.144.4 Restrictions

This fix is part of the REPLICA package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

A PIMD simulation can be initialized with a single data file read via the read_data command. However, this means all quasi-beads in a ring polymer will have identical positions and velocities, resulting in identical trajectories for all quasi-beads. To avoid this, users can simply initialize velocities with different random number seeds assigned to each partition, as defined by the uloop variable, e.g.

\[
\text{velocity all create 300.0 1234${ibead}$ rot yes dist gaussian}
\]

17.144.5 Default

The keyword defaults are method = pimd, fmass = 1.0, sp = 1.0, temp = 300.0, and nhc = 2.

```
17.146.2 Examples

```
fix pl all plumed all plumed plumedfile plumed.dat outfile p.log
```

17.146.3 Description

This fix instructs LAMMPS to call the PLUMED library, which allows one to perform various forms of trajectory analysis on the fly and to also use methods such as umbrella sampling and metadynamics to enhance the sampling of phase space.

The documentation included here only describes the fix plumed command itself. This command is LAMMPS specific, whereas most of the functionality implemented in PLUMED will work with a range of MD codes, and when PLUMED is used as a stand alone code for analysis. The full documentation for PLUMED is available online and included in the PLUMED source code. The PLUMED library development is hosted at https://github.com/plumed/plumed2

A detailed discussion of the code can be found in [Tribello](#).

There is an example input for using this package with LAMMPS in the examples/PACKAGES/plumed directory.

The command to make LAMMPS call PLUMED during a run requires two keyword value pairs pointing to the PLUMED input file and an output file for the PLUMED log. The user must specify these arguments every time PLUMED is to be used. Furthermore, the fix plumed command should appear in the LAMMPS input file after relevant input parameters (e.g. the timestep) have been set.

The `group-ID` entry is ignored. LAMMPS will always pass all the atoms to PLUMED and there can only be one instance of the plumed fix at a time. The way the plumed fix is implemented ensures that the minimum amount of information required is communicated. Furthermore, PLUMED supports multiple, completely independent collective variables, multiple independent biases and multiple independent forms of analysis. There is thus really no restriction in functionality by only allowing only one plumed fix in the LAMMPS input.

The `plumedfile` keyword allows the user to specify the name of the PLUMED input file. Instructions as to what should be included in a plumed input file can be found in the documentation for PLUMED.

The `outfile` keyword allows the user to specify the name of a file in which to output the PLUMED log. This log file normally just repeats the information that is contained in the input file to confirm it was correctly read and parsed. The names of the files in which the results are stored from the various analysis options performed by PLUMED will be specified by the user in the PLUMED input file.

17.146.4 Restart, fix_modify, output, run start/stop, minimize info

When performing a restart of a calculation that involves PLUMED you must include a RESTART command in the PLUMED input file as detailed in the PLUMED documentation. When the restart command is found in the PLUMED input PLUMED will append to the files that were generated in the run that was performed previously. No part of the PLUMED restart data is included in the LAMMPS restart files. Furthermore, any history dependent bias potentials that were accumulated in previous calculations will be read in when the RESTART command is included in the PLUMED input.

The `fix_modify energy` option is supported by this fix to add the energy change from the biasing force added by PLUMED to the global potential energy of the system as part of thermodynamic output. The default setting for this fix is `fix_modify energy yes`.

The `fix_modify virial` option is supported by this fix to add the contribution from the biasing force to the global pressure of the system via the `compute pressure` command. This can be accessed by thermodynamic output. The default setting for this fix is `fix_modify virial yes`.
This fix computes a global scalar which can be accessed by various output commands. The scalar is the PLUMED energy mentioned above. The scalar value calculated by this fix is “extensive”. Note that other quantities of interest can be output by commands that are native to PLUMED.

17.146.5 Restrictions

This fix is part of the PLUMED package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

There can only be one fix plumed command active at a time.

- fix 3 fluid poems group clump1 clump2 clump3
- fix 3 fluid poems file cluster.list
17.147.3 Description

Treats one or more sets of atoms as coupled rigid bodies. This means that each timestep the total force and torque on each rigid body is computed and the coordinates and velocities of the atoms are updated so that the collection of bodies move as a coupled set. This can be useful for treating a large biomolecule as a collection of connected, coarse-grained particles.

The coupling, associated motion constraints, and time integration is performed by the software package Parallelizable Open source Efficient Multibody Software (POEMS) which computes the constrained rigid-body motion of articulated (jointed) multibody systems (Anderson). POEMS was written and is distributed by Prof Kurt Anderson, his graduate student Rudranarayan Mukherjee, and other members of his group at Rensselaer Polytechnic Institute (RPI). Rudranarayan developed the LAMMPS/POEMS interface. For copyright information on POEMS and other details, please refer to the documents in the poems directory distributed with LAMMPS.

This fix updates the positions and velocities of the rigid atoms with a constant-energy time integration, so you should not update the same atoms via other fixes (e.g. nve, nvt, npt, temp/rescale, langevin).

Each body must have a non-degenerate inertia tensor, which means it must contain at least 3 non-collinear atoms. Which atoms are in which bodies can be defined via several options.

For option group, each of the listed groups is treated as a rigid body. Note that only atoms that are also in the fix group are included in each rigid body.

For option molecule, each set of atoms in the group with a different molecule ID is treated as a rigid body.

For option file, sets of atoms are read from the specified file and each set is treated as a rigid body. Each line of the file specifies a rigid body in the following format:

ID type atom1-ID atom2-ID atom3-ID …

ID as an integer from 1 to M (the number of rigid bodies). Type is any integer; it is not used by the fix poems command. The remaining arguments are IDs of atoms in the rigid body, each typically from 1 to N (the number of atoms in the system). Only atoms that are also in the fix group are included in each rigid body. Blank lines and lines that begin with ‘#’ are skipped.

A connection between a pair of rigid bodies is inferred if one atom is common to both bodies. The POEMS solver treats that atom as a spherical joint with 3 degrees of freedom. Currently, a collection of bodies can only be connected by joints as a linear chain. The entire collection of rigid bodies can represent one or more chains. Other connection topologies (tree, ring) are not allowed, but will be added later. Note that if no joints exist, it is more efficient to use the fix rigid command to simulate the system.

When the poems fix is defined, it will print out statistics on the total # of clusters, bodies, joints, atoms involved. A cluster in this context means a set of rigid bodies connected by joints.

For computational efficiency, you should turn off pairwise and bond interactions within each rigid body, as they no longer contribute to the motion. The “neigh_modify exclude” and “delete_bonds” commands can be used to do this if each rigid body is a group.

For computational efficiency, you should only define one fix poems which includes all the desired rigid bodies. LAMMPS will allow multiple poems fixes to be defined, but it is more expensive.

The degrees-of-freedom removed by coupled rigid bodies are accounted for in temperature and pressure computations. Similarly, the rigid body contribution to the pressure virial is also accounted for. The latter is only correct if forces within the bodies have been turned off, and there is only a single fix poems defined.
17.147.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify virial option is supported by this fix to add the contribution due to the added forces and torques on atoms to both the global pressure and per-atom stress of the system via the compute pressure and compute stress/atom commands. The former can be accessed by thermodynamic output. The default setting for this fix is fix_modify virial yes.

The fix_modify bodyforces option is supported by this fix style to set whether per-body forces and torques are computed early or late in a timestep, i.e. at the post-force stage or at the final-integrate stage, respectively.

No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.147.5 Restrictions

This fix is part of the POEMS package. It is only enabled if LAMMPS was built with that package, which also requires the POEMS library be built and linked with LAMMPS. See the Build package page for more info.

17.150.3 Description

These fixes compute induced charges at the interface between two impermeable media with different dielectric constants. The interfaces need to be discretized into vertices, each representing a boundary element. The vertices are treated as if they were regular atoms or particles. `atom_style dielectric` should be used since it defines the additional properties of each interface particle such as interface normal vectors, element areas, and local dielectric mismatch. These fixes also require the use of `pair_style` and `kspace_style` with the `dielectric` suffix. At every time step, given a configuration of the physical charges in the system (such as atoms and charged particles) these fixes compute and update the charge of the interface particles. The interfaces are allowed to move during the simulation with appropriate time integrators (for example, with `fix_rigid`).

Consider an interface between two media: one with dielectric constant of 78 (water), the other of 4 (silica). The interface is discretized into 2000 boundary elements, each represented by an interface particle. Suppose that each interface particle has a normal unit vector pointing from the silica medium to water. The dielectric difference along the normal vector is then 78 - 4 = 74, the mean dielectric value is (78 + 4) / 2 = 41. Each boundary element also has its area and the local mean curvature (which is used by these fixes for computing a correction term in the local electric field). To model charged interfaces, the interface particle will have a non-zero charge value, coming from its area and surface charge density.

For non-interface particles such as atoms and charged particles, the interface normal vectors, element area, and dielectric mismatch are irrelevant. Their local dielectric value is used to rescale their actual charge when computing the Coulombic interactions. For instance, for a cation carrying a charge of +2 (in charge unit) in an implicit solvent with dielectric constant of 40 would have actual charge of +2, and a local dielectric constant value of 40. It is assumed that the particles cannot pass through the interface during the simulation so that its local dielectric constant value does not change.

There are some example scripts for using these fixes with LAMMPS in the `examples/PACKAGES/dielectric` directory. The README file therein contains specific details on the system setup. Note that the example data files show the additional fields (columns) needed for `atom_style dielectric` beyond the conventional fields id, mol, type, q, x, y, and z.

For fix polarize/bem/gmres and fix polarize/bem/icc the induced charges of the atoms in the specified group, which are the vertices on the interface, are computed using the equation:

\[
\sigma_b(s) = \frac{1 - \bar{\epsilon}}{\epsilon} \sigma_f(s) - \epsilon_0 \frac{\Delta\epsilon}{\epsilon} E(s) \cdot n(s)
\]

- \(\sigma_b\) is the induced charge density at the interface vertex \(s\).
- \(\bar{\epsilon}\) is the mean dielectric constant at the interface vertex: \(\bar{\epsilon} = (\epsilon_1 + \epsilon_2)/2\).
- \(\Delta\epsilon\) is the dielectric constant difference at the interface vertex: \(\Delta\epsilon = \epsilon_1 - \epsilon_2\)
- \(\sigma_f\) is the free charge density at the interface vertex
- \(E(s)\) is the electrical field at the vertex
• \( n(s) \) is the unit normal vector at the vertex pointing from medium with \( \epsilon_2 \) to that with \( \epsilon_1 \).

Fix `polarize/bem/gmres` employs the Generalized Minimum Residual (GMRES) as described in (Barros) to solve \( \sigma_b \).

Fix `polarize/bem/icc` employs the successive over-relaxation algorithm as described in (Tyagi) to solve \( \sigma_b \).

The iterative solvers would terminate either when the maximum relative change in the induced charges in consecutive iterations is below the set tolerance, or when the number of iterations reaches \( \text{iter}_\text{max} \) (see below).

Fix `polarize/functional` employs the energy functional variation approach as described in (Jadhao) to solve \( \sigma_b \).

More details on the implementation of these fixes and their recommended use are described in (NguyenTD).

### 17.150.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The `fix_modify` command provides certain options to control the induced charge solver and the initial values of the interface elements:

```
itr_max arg
  arg = maximum number of iterations for convergence
dielectrics ediff emean epsilon area charge
  ediff = dielectric difference
  emean = dielectric mean
  epsilon = local dielectric value
  area = element area
  charge = real interface charge
```

`polarize/bem/gmres` or `polarize/bem/icc` compute a global 2-element vector which can be accessed by various `output` commands. The first element is the number of iterations when the solver terminates (of which the upper bound is set by `iter_max`). The second element is the RMS error.

### 17.150.5 Restrictions

These fixes are part of the DIELECTRIC package. It is only enabled if LAMMPS was built with that package, which requires that also the KSPACE package is installed. See the `Build package` page for more info.

Note that the `polarize/bem/gmres` and `polarize/bem/icc` fixes only support units \([lj, \text{real}, \text{metal}, \text{si}]\) and \([\text{nano}]\) at the moment.

\end{verbatim}

### 17.151.3 Description

Insert finite-size particles or molecules into the simulation box every few timesteps within a specified region until N particles or molecules have been inserted. This is typically used to model the pouring of granular particles into a container under the influence of gravity. For the remainder of this doc page, a single inserted atom or molecule is referred to as a “particle”.

If inserted particles are individual atoms, they are assigned the specified atom type. If they are molecules, the type of each atom in the inserted molecule is specified in the file read by the \textit{molecule} command, and those values are added to the specified atom type. E.g. if the file specifies atom types 1,2,3, and those are the atom types you want for inserted molecules, then specify \texttt{type = 0}. If you specify \texttt{type = 2}, the in the inserted molecule will have atom types 3,4,5.

All atoms in the inserted particle are assigned to two groups: the default group “all” and the group specified in the \textit{fix pour} command (which can also be “all”).

This command must use the \textit{region} keyword to define an insertion volume. The specified region must have been previously defined with a \textit{region} command. It must be of type \textit{block} or a z-axis \textit{cylinder} and must be defined with side = \textit{in}. The cylinder style of region can only be used with 3d simulations.

Individual atoms are inserted, unless the \texttt{mol} keyword is used. It specifies a \textit{template-ID} previously defined using the \textit{molecule} command, which reads a file that defines the molecule. The coordinates, atom types, center-of-mass, moments of inertia, etc, as well as any bond/angle/etc and special neighbor information for the molecule can be specified in the molecule file. See the \textit{molecule} command for details. The only settings required to be in this file are the coordinates and types of atoms in the molecule.

If the molecule template contains more than one molecule, the relative probability of depositing each molecule can be specified by the \texttt{molfrac} keyword. N relative probabilities, each from 0.0 to 1.0, are specified, where N is the number of molecules in the template. Each time a molecule is inserted, a random number is used to sample from the list of relative probabilities. The N values must sum to 1.0.

If you wish to insert molecules via the \texttt{mol} keyword, that will be treated as rigid bodies, use the \texttt{rigid} keyword, specifying as its value the ID of a separate \textit{fix rigid/small} command which also appears in your input script.
If you wish the new rigid molecules (and other rigid molecules) to be thermostatted correctly via `fix rigid/small/nvt` or `fix rigid/small/npt`, then you need to use the “fix_modify dynamic/dof yes” command for the rigid fix. This is to inform that fix that the molecule count will vary dynamically.

If you wish to insert molecules via the `mol` keyword, that will have their bonds or angles constrained via SHAKE, use the `shake` keyword, specifying as its value the ID of a separate `fix shake` command which also appears in your input script.

Each timestep particles are inserted, they are placed randomly inside the insertion volume so as to mimic a stream of poured particles. If they are molecules they are also oriented randomly. Each atom in the particle is tested for overlaps with existing particles, including effects due to periodic boundary conditions if applicable. If an overlap is detected, another random insertion attempt is made; see the `vol` keyword discussion below. The larger the volume of the insertion region, the more particles that can be inserted at any one timestep. Particles are inserted again after enough time has elapsed that the previously inserted particles fall out of the insertion volume under the influence of gravity. Insertions continue every so many timesteps until the desired # of particles has been inserted.

All other keywords are optional with defaults as shown below.

The `diam` option is only used when inserting atoms and specifies the diameters of inserted particles. There are 3 styles: `one`, `range`, or `poly`. For `one`, all particles will have diameter $D$. For `range`, the diameter of each particle will be chosen randomly and uniformly between the specified $D_{lo}$ and $D_{hi}$ bounds. For `poly`, a series of $N_{poly}$ diameters is specified. For each diameter a percentage value from 0.0 to 1.0 is also specified. The $N_{poly}$ percentages must sum to 1.0. For the example shown above with “diam 2 0.7 0.4 1.5 0.6”, all inserted particles will have a diameter of 0.7 or 1.5. 40% of the particles will be small; 60% will be large.

Note that for molecule insertion, the diameters of individual atoms in the molecule can be specified in the file read by the `molecule` command. If not specified, the diameter of each atom in the molecule has a default diameter of 1.0.

The `id` option has two settings which are used to determine the atom or molecule IDs to assign to inserted particles/molecules. In both cases a check is done of the current system to find the maximum current atom and molecule ID of any existing particle. Newly inserted particles and molecules are assigned IDs that increment those max values. For the `max` setting, which is the default, this check is done at every insertion step, which allows for particles to leave the system, and their IDs to potentially be re-used. For the `next` setting this check is done only once when the fix is specified, which can be more efficient if you are sure particles will not be added in some other way.

The `vol` option specifies what volume fraction of the insertion volume will be filled with particles. For particles with a size specified by the `diam range` keyword, they are assumed to all be of maximum diameter $D_{hi}$ for purposes of computing their contribution to the volume fraction.

The higher the volume fraction value, the more particles are inserted each timestep. Since inserted particles cannot overlap, the maximum volume fraction should be no higher than about 0.6. Each timestep particles are inserted, LAMMPS will make up to a total of $M$ tries to insert the new particles without overlaps, where $M = \#$ of inserted particles * Nattempt. If LAMMPS is unsuccessful at completing all insertions, it prints a warning.

The `dens` and `vel` options enable inserted particles to have a range of densities or xy velocities. The specific values for a particular inserted particle will be chosen randomly and uniformly between the specified bounds. Internally, the density value for a particle is converted to a mass, based on the radius (volume) of the particle. The $v_z$ or $v_y$ value for option `vel` assigns a z-velocity (3d) or y-velocity (2d) to each inserted particle.

The `rate` option moves the insertion volume in the z direction (3d) or y direction (2d). This enables pouring particles from a successively higher height over time.
The *ignore* option is useful when running a simulation that used line segment (2d) or triangle (3d) particles, typically to define boundaries for spherical granular particles to interact with. See the *atom_style line or tri* command for details. Lines and triangles store their size, and if the size is large it may overlap (in a spherical sense) with the insertion region, even if the line/triangle is oriented such that there is no actual overlap. This can prevent particles from being inserted. The *ignore* keyword causes the overlap check to skip any line or triangle particles. Obviously you should only use it if there is in fact no overlap of the line or triangle particles with the insertion region.

---

### 17.151.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. This means you must be careful when restarting a pouring simulation, when the restart file was written in the middle of the pouring operation. Specifically, you should use a new fix pour command in the input script for the restarted simulation that continues the operation. You will need to adjust the arguments of the original fix pour command to do this.

Also note that because the state of the random number generator is not saved in restart files, you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior if you adjust the fix pour parameters appropriately.

None of the *fix_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during energy minimization.

### 17.151.5 Restrictions

This fix is part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

For 3d simulations, a gravity fix in the -z direction must be defined for use in conjunction with this fix. For 2d simulations, gravity must be defined in the -y direction.

The specified insertion region cannot be a “dynamic” region, as defined by the *region* command.

### 17.151.6 Related commands

*fix deposit*, *fix gravity*, *region*

### 17.151.7 Default

Insertions are performed for individual particles, i.e. no *mol* setting is defined. If the *mol* keyword is used, the default for *molfrac* is an equal probabilities for all molecules in the template. Additional option defaults are diam = one 1.0, dens = 1.0 1.0, vol = 0.25 50, rate = 0.0, vel = 0.0 0.0 0.0 0.0 0.0 (for 3d), vel = 0.0 0.0 0.0 (for 2d), and id = max.
17.152 fix precession/spin command

fix 1 all precession/spin zeeman 0.1 0.0 0.0 1.0 anisotropy 0.001 0.0 0.0 1.0
```

17.152.3 Description

This fix applies a precession torque to each magnetic spin in the group.

Style `zeeman` is used for the simulation of the interaction between the magnetic spins in the defined group and an external magnetic field:

\[
H_{\text{Zeeman}} = -g \sum_{i=0}^{N} \mu_i \vec{s}_i \cdot \vec{B}_{ext}
\]

with:

- \( \vec{B}_{ext} \) the external magnetic field (in T)
- \( g \) the Lande factor (hard-coded as \( g = 2.0 \))
- \( \vec{s}_i \) the unitary vector describing the orientation of spin \( i \)
- \( \mu_i \) the atomic moment of spin \( i \) given as a multiple of the Bohr magneton \( \mu_B \) (for example, \( \mu_i \approx 2.2 \) in bulk iron).
The field value in Tesla is multiplied by the gyromagnetic ratio, \( g \cdot \mu_B / \hbar \), converting it into a precession frequency in rad.THz (in metal units and with \( \mu_B = 5.788 \cdot 10^{-5} \text{ eV/T} \)).

As a comparison, the figure below displays the simulation of a single spin (of norm \( \mu_i = 1.0 \)) submitted to an external magnetic field of \( |B_{ext}| = 10.0 \text{ Tesla} \) (and oriented along the z axis). The upper plot shows the average magnetization along the external magnetic field axis and the lower plot the Zeeman energy, both as a function of temperature. The reference result is provided by the plot of the Langevin function for the same parameters.

The temperature effects are accounted for by connecting the spin \( i \) to a thermal bath using a Langevin thermostat (see \textit{fix langevin/spin} for the definition of this thermostat).

Style \textit{anisotropy} is used to simulate an easy axis or an easy plane for the magnetic spins in the defined group:

\[
H_{\text{aniso}} = - \sum_{i=1}^{N} K_{an} (\mathbf{r}_i \cdot \mathbf{n}_i)^2
\]

with \( \mathbf{n} \) defining the direction of the anisotropy, and \( K \) (in eV) its intensity. If \( K > 0 \), an easy axis is defined, and if \( K < 0 \), an easy plane is defined.

Style \textit{cubic} is used to simulate a cubic anisotropy, with three possible easy axis for the magnetic spins in the defined group:

\[
H_{\text{cubic}} = - \sum_{i=1}^{N} K_1 \left[ (\mathbf{s}_i \cdot \mathbf{n}_1)^2 (\mathbf{s}_i \cdot \mathbf{n}_2)^2 + (\mathbf{s}_i \cdot \mathbf{n}_2)^2 (\mathbf{s}_i \cdot \mathbf{n}_3)^2 + (\mathbf{s}_i \cdot \mathbf{n}_3)^2 (\mathbf{s}_i \cdot \mathbf{n}_1)^2 \right] + K_2 (\mathbf{s}_i \cdot \mathbf{n}_1)^2 (\mathbf{s}_i \cdot \mathbf{n}_2)^2 (\mathbf{s}_i \cdot \mathbf{n}_3)^2
\]

with \( K_1 \) and \( K_2 \) (in eV) the intensity coefficients and \( \mathbf{n}_1, \mathbf{n}_2 \) and \( \mathbf{n}_3 \) defining the three anisotropic directions defined by the command (from \( n1x \) to \( n3z \)). For \( \mathbf{n}_1 = (100), \mathbf{n}_2 = (010), \) and \( \mathbf{n}_3 = (001), \) \( K_1 < 0 \) defines an iron type anisotropy (easy axis along the \((001)\)-type cube edges), and \( K_1 > 0 \) defines a nickel type anisotropy (easy axis along the \((111)\)-type cube diagonals). \( K_2 > 0 \) also defines easy axis along the \((111)\)-type cube diagonals. See chapter 2 of \textit{(Skomski)} for more details on cubic anisotropies.

17.152. \textit{fix precession/spin command}
Style \textit{stt} is used to simulate the interaction between the spins and a spin-transfer torque. See equation (7) of \textit{(Chirac)} for more details about the implemented spin-transfer torque term.

In all cases, the choice of \((xyz)\) only imposes the vector directions for the forces. Only the direction of the vector is important; its length is ignored (the entered vectors are normalized).

Those styles can be combined within one single command line.

\textbf{Note:} The norm of all vectors defined with the precession/spin command have to be non-zero. For example, defining “fix 1 all precession/spin zeeman 0.1 0.0 0.0 0.0” would result in an error message. Since those vector components are used to compute the inverse of the field (or anisotropy) vector norm, setting a zero-vector would result in a division by zero.

### 17.152.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about this fix is written to \textit{binary restart files}.

The \texttt{fix\_modify energy} option is supported by this fix to add the energy associated with the spin precession torque to the global potential energy of the system as part of \textit{thermodynamic output}. The default setting for this fix is \texttt{fix\_modify energy no}.

This fix computes a global scalar which can be accessed by various \textit{output commands}. The scalar is the potential energy (in energy units) discussed in the previous paragraph. The scalar value is an “extensive” quantity.

No information about this fix is written to \textit{binary restart files}.

### 17.152.5 Restrictions

The \texttt{precession/spin} style is part of the SPIN package. This style is only enabled if LAMMPS was built with this package, and if the \texttt{atom\_style “spin”} was declared. See the \texttt{Build package} page for more info.

### 17.152.6 Related commands

\texttt{atom\_style spin}

### 17.152.7 Default

\texttt{none}

# 17.153 fix press/berendsen command

## 17.153.1 Syntax

```plaintext
fix ID group-ID press/berendsen keyword value ...
```

- ID, group-ID are documented in `fix` command
- press/berendsen = style name of this fix command
  - one or more keyword value pairs may be appended
  - keyword = `iso` or `aniso` or `x` or `y` or `z` or `couple` or `dilate` or `modulus`
    - `iso` or `aniso` values = `Pstart Pstop Pdamp`
    - `Pstart, Pstop` = scalar external pressure at start/end of run (pressure units)
    - `Pdamp` = pressure damping parameter (time units)
    - `x` or `y` or `z` values = `Pstart Pstop Pdamp`
    - `Pstart, Pstop` = external stress tensor component at start/end of run (pressure units)
    - `Pdamp` = stress damping parameter (time units)
    - `couple` = `none` or `xyz` or `xy` or `yz` or `xz`
    - `modulus` value = bulk modulus of system (pressure units)
    - `dilate` value = `all` or `partial`

## 17.153.2 Examples

```plaintext
fix 1 all press/berendsen iso 0.0 0.0 1000.0
fix 2 all press/berendsen aniso 0.0 0.0 1000.0 dilate partial
```

## 17.153.3 Description

Reset the pressure of the system by using a Berendsen barostat (Berendsen), which rescales the system volume and (optionally) the atoms coordinates within the simulation box every timestep.

Regardless of what atoms are in the fix group, a global pressure is computed for all atoms. Similarly, when the size of the simulation box is changed, all atoms are re-scaled to new positions, unless the keyword `dilate` is specified with a value of `partial`, in which case only the atoms in the fix group are re-scaled. The latter can be useful for leaving the coordinates of atoms in a solid substrate unchanged and controlling the pressure of a surrounding fluid.

**Note:** Unlike the `fix npt` or `fix nph` commands which perform Nose/Hoover barostatting AND time integration, this fix does NOT perform time integration. It only modifies the box size and atom coordinates to effect barostatting. Thus you must use a separate time integration fix, like `fix nve` or `fix nvt` to actually update the positions and velocities of atoms. This fix can be used in conjunction with thermostatting fixes to control the temperature, such as `fix nvt` or `fix langevin` or `fix temp/berendsen`.

See the Howto baroostat page for a discussion of different ways to perform barostatting.

The barostat is specified using one or more of the `iso`, `aniso`, `x`, `y`, `z`, and `couple` keywords. These keywords give you the ability to specify the 3 diagonal components of an external stress tensor, and to couple various of these components together so that the dimensions they represent are varied together during a constant-pressure simulation. Unlike the
fix npt and fix nph commands, this fix cannot be used with triclinic (non-orthogonal) simulation boxes to control all 6 components of the general pressure tensor.

The target pressures for each of the 3 diagonal components of the stress tensor can be specified independently via the \( x \), \( y \), \( z \) keywords, which correspond to the 3 simulation box dimensions. For each component, the external pressure or tensor component at each timestep is a ramped value during the run from \( P_{\text{start}} \) to \( P_{\text{stop}} \). If a target pressure is specified for a component, then the corresponding box dimension will change during a simulation. For example, if the \( y \) keyword is used, the \( y \)-box length will change. A box dimension will not change if that component is not specified, although you have the option to change that dimension via the fix deform command.

For all barostat keywords, the \( P_{\text{damp}} \) parameter determines the time scale on which pressure is relaxed. For example, a value of 10.0 means to relax the pressure in a timespan of (roughly) 10 time units (tau or fs or ps - see the units command).

**Note:** A Berendsen barostat will not work well for arbitrary values of \( P_{\text{damp}} \). If \( P_{\text{damp}} \) is too small, the pressure and volume can fluctuate wildly; if it is too large, the pressure will take a very long time to equilibrate. A good choice for many models is a \( P_{\text{damp}} \) of around 1000 timesteps. However, note that \( P_{\text{damp}} \) is specified in time units, and that timesteps are NOT the same as time units for most units settings.

**Note:** The relaxation time is actually also a function of the bulk modulus of the system (inverse of isothermal compressibility). The bulk modulus has units of pressure and is the amount of pressure that would need to be applied (isotropically) to reduce the volume of the system by a factor of 2 (assuming the bulk modulus was a constant, independent of density, which it’s not). The bulk modulus can be set via the keyword modulus. The \( P_{\text{damp}} \) parameter is effectively multiplied by the bulk modulus, so if the pressure is relaxing faster than expected or desired, increasing the bulk modulus has the same effect as increasing \( P_{\text{damp}} \). The converse is also true. LAMMPS does not attempt to guess a correct value of the bulk modulus; it just uses 10.0 as a default value which gives reasonable relaxation for a Lennard-Jones liquid, but will be way off for other materials and way too small for solids. Thus you should experiment to find appropriate values of \( P_{\text{damp}} \) and/or the modulus when using this fix.

The \texttt{couple} keyword allows two or three of the diagonal components of the pressure tensor to be “coupled” together. The value specified with the keyword determines which are coupled. For example, \( xz \) means the \( P_{xx} \) and \( P_{zz} \) components of the stress tensor are coupled. \( xyz \) means all 3 diagonal components are coupled. Coupling means two things: the instantaneous stress will be computed as an average of the corresponding diagonal components, and the coupled box dimensions will be changed together in lockstep, meaning coupled dimensions will be dilated or contracted by the same percentage every timestep. The \( P_{\text{start}}, P_{\text{stop}}, P_{\text{damp}} \) parameters for any coupled dimensions must be identical. \texttt{Couple xyz} can be used for a 2d simulation; the \( z \) dimension is simply ignored.

The \texttt{iso} and \texttt{aniso} keywords are simply shortcuts that are equivalent to specifying several other keywords together. The keyword \texttt{iso} means couple all 3 diagonal components together when pressure is computed (hydrostatic pressure), and dilate/contract the dimensions together. Using “iso \( P_{\text{start}}, P_{\text{stop}}, P_{\text{damp}} \)” is the same as specifying these 4 keywords:

\begin{verbatim}
x Pstart Pstop Pdamp 
y Pstart Pstop Pdamp 
z Pstart Pstop Pdamp 
couple xyz
\end{verbatim}

The keyword \texttt{aniso} means \( x \), \( y \), and \( z \) dimensions are controlled independently using the \( P_{xx}, P_{yy}, \) and \( P_{zz} \) components of the stress tensor as the driving forces, and the specified scalar external pressure. Using “aniso \( P_{\text{start}}, P_{\text{stop}}, P_{\text{damp}} \)” is the same as specifying these 4 keywords:
This fix computes a temperature and pressure each timestep. To do this, the fix creates its own computes of style “temp” and “pressure”, as if these commands had been issued:

```
compute fix-ID_temp group-ID temp
compute fix-ID_press group-ID pressure fix-ID_temp
```

See the `compute temp` and `compute pressure` commands for details. Note that the IDs of the new computes are the `fix-ID + underscore + “temp”` or `fix_ID + underscore + “press”`, and the group for the new computes is the same as the fix group.

Note that these are NOT the computes used by thermodynamic output (see the `thermo_style` command) with ID = `thermo_temp` and `thermo_press`. This means you can change the attributes of this fix’s temperature or pressure via the `compute_modify` command or print this temperature or pressure during thermodynamic output via the `thermo_style custom` command using the appropriate compute-ID. It also means that changing attributes of `thermo_temp` or `thermo_press` will have no effect on this fix.

### 17.153.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The `fix_modify temp` and `press` options are supported by this fix. You can use them to assign a `compute` you have defined to this fix which will be used in its temperature and pressure calculations. If you do this, note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

No global or per-atom quantities are stored by this fix for access by various output commands.

This fix can ramp its target pressure over multiple runs, using the `start` and `stop` keywords of the `run` command. See the `run` command for details of how to do this.

This fix is not invoked during energy minimization.

### 17.153.5 Restrictions

Any dimension being adjusted by this fix must be periodic.

### 17.153.6 Related commands

`fix nve, fix nph, fix npt, fix temp/berendsen, fix_modify`
17.153.7 Default

The keyword defaults are dilate = all, modulus = 10.0 in units of pressure for whatever units are defined.

17.154 fix print command

17.154.1 Syntax

```plaintext
fix ID group-ID print N string keyword value ...
```

- ID, group-ID are documented in `fix` command
- print = style name of this fix command
- N = print every N steps; N can be a variable (see below)
- string = text string to print with optional variable names
- zero or more keyword/value pairs may be appended
- keyword = `file` or `append` or `screen` or `title`
  
  - `file` value = filename
  - `append` value = filename
  - `screen` value = yes or no
  - `title` value = string
    
    string = text to print as 1st line of output file

17.154.2 Examples

```plaintext
fix extra all print 100 "Coords of marker atom = $x $y $z"
fix extra all print 100 "Coords of marker atom = $x $y $z" file coord.txt
```

17.154.3 Description

Print a text string every N steps during a simulation run. This can be used for diagnostic purposes or as a debugging tool to monitor some quantity during a run. The text string must be a single argument, so it should be enclosed in single or double quotes if it is more than one word. If it contains variables it must be enclosed in double quotes to insure they are not evaluated when the input script line is read, but will instead be evaluated each time the string is printed.

Note: As discussed on the `Commands parse` doc page, the text string can use “immediate” variables, specified as $\text{(formula)}$ with parenthesis, where the numeric formula has the same syntax as equal-style variables described on the `variable` doc page. This is a convenient way to evaluate a formula immediately without using the variable command to define a named variable and then use that variable in the text string. The formula can include a trailing colon and format string which determines the precision with which the numeric value is output. This is also explained on the `Commands parse` doc page.
Instead of a numeric value, \( N \) can be specified as an equal-style variable, which should be specified as \( v\_name \), where name is the variable name. In this case, the variable is evaluated at the beginning of a run to determine the next timestep at which the string will be written out. On that timestep, the variable will be evaluated again to determine the next timestep, etc. Thus the variable should return timestep values. See the stagger() and logfreq() and stride() math functions for equal-style variables, as examples of useful functions to use in this context. For example, the following commands will print output at timesteps 10, 20, 30, 100, 200, 300, 1000, 2000, etc:

```
variable s equal logfreq(10,3,10)
fix extra all print v_s "Coords of marker atom = $x $y $z"
```

The specified group-ID is ignored by this fix.

See the \texttt{variable} command for a description of equal style variables which are the most useful ones to use with the fix print command, since they are evaluated afresh each timestep that the fix print line is output. Equal-style variables calculate formulas involving mathematical operations, atom properties, group properties, thermodynamic properties, global values calculated by a compute or fix, or references to other variables.

If the \texttt{file} or \texttt{append} keyword is used, a filename is specified to which the output generated by this fix will be written. If \texttt{file} is used, then the filename is overwritten if it already exists. If \texttt{append} is used, then the filename is appended to if it already exists, or created if it does not exist.

If the \texttt{screen} keyword is used, output by this fix to the screen and logfile can be turned on or off as desired.

The \texttt{title} keyword allow specification of the string that will be printed as the first line of the output file, assuming the \texttt{file} keyword was used. By default, the title line is as follows:

```
# Fix print output for fix ID
```

where ID is replaced with the fix-ID.

**17.154.4 Restart, fix\_modify, output, run start/stop, minimize info**

No information about this fix is written to binary restart files. None of the \texttt{fix\_modify} options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the \texttt{start/stop} keywords of the \texttt{run} command. This fix is not invoked during energy minimization.

**17.154.5 Restrictions**

none

**17.154.6 Related commands**

\texttt{variable, print}
17.154.7 Default

The option defaults are no file output, screen = yes, and title string as described above.

17.155 fix propel/self command

17.155.1 Syntax

```
fix ID group-ID propel/self mode magnitude keyword values
```

- ID, group-ID are documented in `fix` command
- propel/self = style name of this fix command
- mode = dipole or velocity or quat
- magnitude = magnitude of self-propulsion force
- zero or one keyword/value pairs may be appended
- keyword = qvector
  
  qvector value = direction of force in ellipsoid frame
  sx, sy, sz = components of qvector

17.155.2 Examples

```
fix active all propel/self dipole 40.0
fix active all propel/self velocity 10.0
fix active all propel/self quat 15.7 qvector 1.0 0.0 0.0
```

17.155.3 Description

Add a force to each atom in the group due to a self-propulsion force. The force is given by

\[ F_i = f_P e_i \]

where \( i \) is the particle the force is being applied to, \( f_P \) is the magnitude of the force, and \( e_i \) is the vector direction of the force. The specification of \( e_i \) is based on which of the three keywords (`dipole` or `velocity` or `quat`) one selects.

For mode `dipole`, \( e_i \) is just equal to the dipole vectors of the atoms in the group. Therefore, if the dipoles are not unit vectors, the \( e_i \) will not be unit vectors.

**Note:** If another command changes the magnitude of the dipole, this force will change accordingly (since \( |e_i| \) will change, which is physically equivalent to re-scaling \( f_P \) while keeping \( |e_i| \) constant), and no warning will be provided by LAMMPS. This is almost never what you want, so ensure you are not changing dipole magnitudes with another LAMMPS fix or pair style. Furthermore, self-propulsion forces (almost) always set \( e_i \) to be a unit vector for all times, so it’s best to set all the dipole magnitudes to 1.0 unless you have a good reason not to (see the `set` command on how to do this).

For mode `velocity`, \( e_i \) points in the direction of the current velocity (a unit-vector). This can be interpreted as a velocity-dependent friction, as proposed by e.g. (Erdmann).
For mode \textit{quat}, \( e_i \) points in the direction of a unit vector, oriented in the coordinate frame of the ellipsoidal particles, which defaults to point along the x-direction. This default behavior can be changed by via the \textit{quatvec} keyword.

The optional \textit{quatvec} keyword specifies the direction of self-propulsion via a unit vector \((sx, sy, sz)\). The arguments \(sx\), \(sy\), and \(sz\), are defined within the coordinate frame of the atom’s ellipsoid. For instance, for an ellipsoid with long axis along its x-direction, if one wanted the self-propulsion force to also be along this axis, set \(sx\) equal to 1 and \(sy\), \(sz\) both equal to zero. This keyword may only be specified for mode \textit{quat}.

\textbf{Note:} In using keyword \textit{quatvec}, the three arguments \(sx\), \(sy\), and \(sz\) will be automatically normalized to components of a unit vector internally to avoid users having to explicitly do so themselves. Therefore, in mode \textit{quat}, the vectors \(e_i\) will always be of unit length.

Along with adding a force contribution, this fix can also contribute to the virial (pressure) of the system, defined as

\[ f_P \sum_i <e_i.r_i> / (dV), \]

where \(r_i\) is the unwrapped coordinate of particle \(i\) in the case of periodic boundary conditions. See \cite{Winkler} for a discussion of this active pressure contribution.

For modes \textit{dipole} and \textit{quat}, this fix is by default included in pressure computations.

For mode \textit{velocity}, this fix is by default not included in pressure computations.

\textbf{Note:} In contrast to equilibrium systems, pressure of active systems in general depends on the geometry of the container. The active pressure contribution as calculated in this fix is only valid for certain boundary conditions (spherical walls, rectangular walls, or periodic boundary conditions). For other geometries, the pressure must be measured via explicit calculation of the force per unit area on a wall, and so one must not calculate it using this fix. (Use \texttt{fix_modify} as described below to turn off the virial contribution of this fix). Again, see \cite{Winkler} for discussion of why this is the case.

Furthermore, when dealing with active systems, the temperature is no longer well defined. Therefore, one should ensure that the \textit{virial} flag is used in the \texttt{compute pressure} command (turning off temperature contributions).

### 17.155.4 Restart, \texttt{fix_modify}, output, run start/stop, minimize info

No information about this fix is written to \texttt{binary restart files}.

The \texttt{fix_modify virial} option is supported by this fix to add the contribution due to the added forces on atoms to the system’s virial as part of \texttt{thermodynamic output}. The default is \texttt{virial yes} for keywords \textit{dipole} and \textit{quat}. The default is \texttt{virial no} for keyword \textit{velocity}.

No parameter of this fix can be used with the \texttt{start/stop} keywords of the \texttt{run} command.

### 17.155.5 Restrictions

With keyword \textit{dipole}, this fix only works when the DIPOLE package is enabled. See the \texttt{Build package} page for more info.

This fix is part of the BROWNIAN package. It is only enabled if LAMMPS was built with that package. See the \texttt{Build package} doc page for more info.
17.155.6 Related commands

fix efield, fix setforce, fix addforce

17.155.7 Default

17.156 fix property/atom command

Accelerator Variants: property/atom/kk

17.156.1 Syntax

```
fix ID group-ID property/atom name1 name2 ... keyword value ...
```

- ID, group-ID are documented in fix command
- property/atom = style name of this fix command
- name1,name2,... = mol or q or rmass or i_name or d_name or i2_name or d2_name
  - mol = molecule IDs
  - q = charge
  - rmass = per-atom mass
  - i_name = new integer vector referenced by name
  - d_name = new floating-point vector referenced by name
  - i2_name = new integer array referenced by name
  - d2_name = new floating-point array referenced by name
  - i2_name arg = N = number of columns in the array
  - d2_name arg = N = number of columns in the array
- zero of more keyword/value pairs may be appended
- keyword = ghost
  - ghost value = no or yes for whether ghost atom info in communicated

17.156.2 Examples

```
fix 1 all property/atom mol
fix 1 all property/atom i_myflag1 i_myflag2
fix 1 all property/atom d2_sxyz 3 ghost yes
```
17.156.3 Description

Create one or more additional per-atom vectors or arrays to store information about atoms and to use during a simulation. The specified group-ID is ignored by this fix.

The atom style used for a simulation defines a set of per-atom properties, as explained on the atom_style and read_data doc pages. The latter command defines these properties for each atom in the system when a data file is read. This fix augments the set of per-atom properties with new custom ones. This can be useful in several scenarios.

If the atom style does not define molecule IDs, per-atom charge, or per-atom mass, they can be added using the mol, q or rmass keywords. This could be useful to define “molecules” to use as rigid bodies with the fix rigid command, or to carry around an extra flag with atoms (stored as a molecule ID) that can be used by various commands like compute chunk/atom to group atoms without having to use the group command (which is limited to a total of 32 groups including all).

Another application is to use the rmass flag in order to have per-atom masses instead of per-type masses. This could be used to study isotope effects with partial isotope substitution. See below for an example of simulating a mixture of light and heavy water with the TIP4P water potential.

An alternative to using fix property/atom for these examples is to use an atom style that does define molecule IDs or charge or per-atom mass (indirectly via diameter and density) or to use a hybrid atom style that combines two or more atom styles to provide the union of all their atom properties. However, this has two practical drawbacks: first, it typically necessitates changing the format of the Atoms section in the data file and second, it may define additional properties that are not needed such as bond lists, which incurs some overhead when there are no bonds.

In the future, we may add additional existing per-atom properties to fix property/atom, similar to mol, q or rmass, which “turn-on” specific properties defined by some atom styles, so they can be easily used by atom styles that do not define them.

More generally, the i_name and d_name options allow one or more new custom per-atom vectors to be defined. Likewise the i2_name and d2_name options allow one or more custom per-atom arrays to be defined. The i2_name and d2_name options take an argument N which specifies the number of columns in the per-atom array, i.e. the number of attributes associated with each atom. N >= 1 is required.

Each name must be unique and can use alphanumeric or underscore characters. These vectors and arrays can store whatever values you decide are useful in your simulation. As explained below there are several ways to initialize, access, and output these values, via input script commands, data files, and in new code you add to LAMMPS.

This is effectively a simple way to add per-atom properties to a model without needing to write code for a new atom style that defines the properties. Note however that implementing a new atom style allows new atom properties to be more tightly and seamlessly integrated with the rest of the code.

The new atom properties encode values that migrate with atoms to new processors and are written to restart files. If you want the new properties to also be defined for ghost atoms, then use the ghost keyword with a value of yes. This will invoke extra communication when ghost atoms are created (at every re-neighboring) to insure the new properties are also defined for the ghost atoms.

Properties on ghost atoms

If you use the mol, q or rmass names, you most likely want to set ghost yes, since these properties are stored with ghost atoms if you use an atom_style that defines them. Many LAMMPS operations that use molecule IDs or charge, such as neighbor lists and pair styles, will expect ghost atoms to have these values. LAMMPS will issue a warning it you define those vectors but do not set ghost yes.

Limitations on ghost atom properties

17.156. fix property/atom command
The specified properties for ghost atoms are not updated every timestep, but only once every few steps when neighbor lists are re-built. Thus the `ghost` keyword is suitable for static properties, like molecule IDs, but not for dynamic properties that change every step. For the latter, the code you add to LAMMPS to change the properties will also need to communicate their new values to/from ghost atoms, an operation that can be invoked from within a `pair style` or `fix` or `compute` that you write.

This fix is one of a small number that can be defined in an input script before the simulation box is created or atoms are defined. This is so it can be used with the `read_data` command as described next.

Per-atom properties that are defined by the `atom style` are initialized when atoms are created, e.g. by the `read_data` or `create_atoms` commands. The per-atom properties defined by this fix are not. So you need to initialize them explicitly.

Thus these commands:

```
fix prop all property/atom mol d_flag
read_data data.txt fix prop NULL Molecules
```

would allow a data file to have a section like this:

```
Molecules
1 4 1.5
2 4 3.0
3 10 1.0
4 10 1.0
5 10 1.0
...
N 763 4.5
```

where N is the number of atoms, the first field on each line is the atom-ID, the next two are a molecule-ID and a floating point value that will be stored in a new property called “flag”. If a per-atom array was specified in the fix property/atom command then the N values for that array must be specified consecutively for that property on each line. Note that the order of values on each line corresponds to the order of custom names in the fix property/atom command.

Note that the the lines of per-atom properties can be listed in any order. Also note that all the per-atom properties specified by the fix ID (prop in this case) must be included on each line in the specified data file section (Molecules in this case).

Another way of initializing the new properties is via the `set` command. For example, if you wanted molecules defined for every set of 10 atoms, based on their atom-IDs, these commands could be used:

```
fix prop all property/atom mol
variable cluster atom ((id-1)/10)+1
set atom * mol v_cluster
```

The `atom-style variable` will create values for atoms with IDs 31,32,33,...40 that are 4.0,4.1,4.2,...,4.9. When the `set` commands assigns them to the molecule ID for each atom, they will be truncated to an integer value, so atoms 31-40 will all be assigned a molecule ID of 4.

Note that `atomfile-style variables` can also be used in place of atom-style variables, which means in this case that the molecule IDs could be read-in from a separate file and assigned by the `set` command. This allows you to initialize new per-atom properties in a completely general fashion.
For new atom properties specified as \( i\_name, d\_name, i2\_name, \) or \( d2\_name \), the \texttt{dump custom} and \texttt{compute property/atom} commands can access their values. This means that the values can be used accessed by fixes like \texttt{fix ave/atom}, accessed by other computes like \texttt{compute reduce}, or used in \texttt{atom-style variables}.

For example, these commands will output both the instantaneous and time-averaged values of two new properties to a custom dump file:

\begin{verbatim}
fix myprops all property/atom i_flag1 d_flag2
compute 1 all property/atom i_flag1 d_flag2
fix 1 all ave/atom 10 10 100 c_1[1] c_1[2]
dump 1 all custom 100 tmp.dump id x y z i_flag1 d_flag2 f_1[1] f_1[2]
\end{verbatim}

If you wish to add new \texttt{pair styles}, \texttt{fixes}, or \texttt{computes} that use the per-atom properties defined by this fix, see the \texttt{Modify atom} doc page which has details on how the custom properties of this fix can be accessed from added classes.

Here is an example of using per-atom masses with TIP4P water to study isotope effects. When setting up simulations with the \texttt{TIP4P pair styles} for water, you have to provide exactly one atom type each to identify the water oxygen and hydrogen atoms. Since the atom mass is normally tied to the atom type, this makes it impossible to study multiple isotopes in the same simulation. With \texttt{fix property/atom rmass} however, the per-type masses are replaced by per-atom masses. Assuming you have a working input deck for regular TIP4P water, where water oxygen is atom type 1 and water hydrogen is atom type 2, the following lines of input script convert this to using per-atom masses:

\begin{verbatim}
fix Isotopes all property/atom rmass ghost yes
set type 1 mass 15.9994
set type 2 mass 1.008
\end{verbatim}

When writing out the system data with the \texttt{write data} command, there will be a new section named with the fix-ID (i.e. \texttt{Isotopes} in this case). Alternatively, you can take an existing data file and just add this \texttt{Isotopes} section with one line per atom containing atom-ID and mass. Either way, the extended data file can be read back with:

\begin{verbatim}
fix Isotopes all property/atom rmass ghost yes
read_data tip4p-isotopes.data fix Isotopes NULL Isotopes
\end{verbatim}

Please note that the first \texttt{Isotopes} refers to the fix-ID and the second to the name of the section. The following input script code will now change the first 100 water molecules in this example to heavy water:

\begin{verbatim}
group hwat id 2:300:3
group hwat id 3:300:3
set group hwat mass 2.0141018
\end{verbatim}

Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \texttt{Accelerator packages} page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \texttt{Build package} page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \texttt{-suffix} command-line switch when you invoke LAMMPS, or you can use the \texttt{suffix} command in your input script.

See the \texttt{Accelerator packages} page for more instructions on how to use the accelerated styles effectively.
17.156.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the per-atom values it stores to binary restart files, so that the values can be restored when a simulation is restarted. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

**Warning:** When reading data from a restart file, this fix command has to be specified after the read_restart command and exactly the same was in the input script that created the restart file. LAMMPS will only check whether a fix is of the same style and has the same fix ID and in case of a match will then try to initialize the fix with the data stored in the binary restart file. If the names and associated data types in the new fix property/atom command do not match the old one exactly, data can be corrupted or LAMMPS may crash. If the fix is specified before the read_restart command its data will not be restored.

None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.156.5 Restrictions

none

17.156.7 Default

The default keyword value is ghost = no.

17.157 fix python/invoke command

17.157.1 Syntax

| fix ID group-ID python/invoke N callback function_name |

- ID, group-ID are ignored by this fix
- python/invoke = style name of this fix command
- N = execute every N steps
- callback = post_force or end_of_step
  
  - post_force = callback after force computations on atoms every N time steps
  - end_of_step = callback after every N time steps
17.157.2 Examples

```python
post_force_callback here
from lammps import lammps

def post_force_callback(lammps_ptr, vflag):
    lmp = lammps(ptr=lammps_ptr)
    # access LAMMPS state using Python interface

end_of_step_callback here

def end_of_step_callback(lammps_ptr):
    lmp = lammps(ptr=lammps_ptr)
    # access LAMMPS state using Python interface

fix pf all python/invoke 50 post_force post_force_callback
fix eos all python/invoke 50 end_of_step end_of_step_callback
```

17.157.3 Description

This fix allows you to call a Python function during a simulation run. The callback is either executed after forces have been applied to atoms or at the end of every N time steps.

Callback functions must be declared in the global scope of the active Python interpreter. This can either be done by defining it inline using the python command or by importing functions from other Python modules. If LAMMPS is driven using the library interface from Python, functions defined in the driving Python interpreter can also be executed.

Each callback is given a pointer object as first argument. This can be used to initialize an instance of the lammps Python interface, which gives access to the LAMMPS state from Python.

**Warning:** While you can access the state of LAMMPS via library functions from these callbacks, trying to execute input script commands will in the best case not work or in the worst case result in undefined behavior.

17.157.4 Restrictions

This fix is part of the PYTHON package. It is only enabled if LAMMPS was built with that package. See the **Build package** page for more info.

Building LAMMPS with the PYTHON package will link LAMMPS with the Python library on your system. Settings to enable this are in the lib/python/Makefile.lammps file. See the lib/python/README file for information on those settings.
17.157.5 Related commands

python command

17.158 fix python/move command

17.158.1 Syntax

```python
fix python/move pymodule.CLASS
pymodule.CLASS = use class CLASS in module/file pymodule to compute how to move atoms
```

17.158.2 Examples

```python
fix 1 all python/move py_nve.NVE
fix 1 all python/move py_nve.NVE_OPT
```

17.158.3 Description

The `python/move` fix style provides a way to define ways how particles are moved during an MD run from python script code, that is loaded from a file into LAMMPS and executed at the various steps where other fixes can be executed. This python script must contain specific python class definitions.

This allows to implement complex position updates and also modified time integration methods. Due to python being an interpreted language, however, the performance of this fix can be moderately to significantly slower than the corresponding C++ code. For specific cases, this performance penalty can be limited through effective use of NumPy.

The python module file has to start with the following code:

```python
from __future__ import print_function
import lammps
import ctypes
import traceback
import numpy as np
#
class LAMMPSFix(object):
    def __init__(self, ptr, group_name="all"):
        self.lmp = lammps.lammps(ptr=ptr)
        self.group_name = group_name
#
class LAMMPSFixMove(LAMMPSFix):
    def __init__(self, ptr, group_name="all"):
        super(LAMMPSFixMove, self).__init__(ptr, group_name)
#
    def init(self):
        pass
#
    def initial_integrate(self, vflag):
```

(continues on next page)
Any classes implementing new atom motion functionality have to be derived from the LAMMPSFixMove class, over-riding the available methods as needed.

Examples for how to do this are in the examples/python folder.

17.158.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.158.5 Restrictions

This pair style is part of the PYTHON package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

17.159 fix qbmsst command

17.159.1 Syntax

fix ID group-ID qbmsst dir shockvel keyword value ...

- ID, group-ID are documented in fix command
• qbmsst = style name of this fix
• dir = x or y or z
• shockvel = shock velocity (strictly positive, velocity units)
• zero or more keyword/value pairs may be appended
• keyword = q or mu or p0 or v0 or e0 or tscale or damp or seed or f_max or N_f or eta or beta or T_init
  
  q value = cell mass-like parameter (mass^2/distance^4 units)
mu value = artificial viscosity (mass/distance/time units)
p0 value = initial pressure in the shock equations (pressure units)
v0 value = initial simulation cell volume in the shock equations (distance^3 units)
e0 value = initial total energy (energy units)
tscale value = reduction in initial temperature (unitless fraction between 0.0 and 1.0)
damp value = damping parameter (time units) inverse of friction gamma
seed value = random number seed (positive integer)
f_max value = upper cutoff frequency of the vibration spectrum (1/time units)
N_f value = number of frequency bins (positive integer)
eta value = coupling constant between the shock system and the quantum thermal bath (positive unitless)
beta value = the quantum temperature is updated every beta time steps (positive integer)
T_init value = quantum temperature for the initial state (temperature units)

17.159.2 Examples

```plaintext
# (liquid methane modeled with the REAX force field, real units)
fix 1 all qbmsst z 0.122 q 25 mu 0.9 tscale 0.01 damp 200 seed 35082 f_max 0.3 N_f 100
    eta 1 beta 400 T_init 110
# (quartz modeled with the BKS force field, metal units)
fix 2 all qbmsst z 72 q 40 tscale 0.05 damp 1 seed 47508 f_max 120.0 N_f 100 eta 1.0
    beta 500 T_init 300
```

Two example input scripts are given, including shocked α-quartz and shocked liquid methane. The input script first equilibrates an initial state with the quantum thermal bath at the target temperature and then applies fix qbmsst to simulate shock compression with quantum nuclear correction. The following two figures plot relevant quantities for shocked α-quartz.

![Coupling the Initial State with the QTB T_qm = 300K](image)

Figure 1. Classical temperature $T_{cl} = \sum \frac{m_i v_i^2}{2 N_k T_{qm}}$ vs. time for coupling the α-quartz initial state with the quantum thermal bath at target quantum temperature $T_{qm} = 300K$. The NpH ensemble is used for time integration while QTB provides the colored random force. $T_{cl}$ converges at the timescale of damp which is set to be 1 ps.
17.159.3 Description

This command performs the Quantum-Bath coupled Multi-Scale Shock Technique (QBMSST) integration. See \textit{(Qi)} for a detailed description of this method. QBMSST provides description of the thermodynamics and kinetics of shock processes while incorporating quantum nuclear effects. The \textit{shockvel} setting determines the steady shock velocity that will be simulated along direction \textit{dir}.

Quantum nuclear effects (\textit{fix qtb}) can be crucial especially when the temperature of the initial state is below the classical limit or there is a great change in the zero point energies between the initial and final states. Theoretical post processing quantum corrections of shock compressed water and methane have been reported as much as 30\% of the temperatures \textit{(Goldman)}. A self-consistent method that couples the shock to a quantum thermal bath described by a colored noise Langevin thermostat has been developed by Qi et al \textit{(Qi)} and applied to shocked methane. The onset of chemistry is reported to be at a pressure on the shock Hugoniot that is 40\% lower than observed with classical molecular dynamics.

It is highly recommended that the system be already in an equilibrium state with a quantum thermal bath at temperature of \textit{T_init}. The \textit{fix command} \textit{fix qtb} at constant temperature \textit{T_init} could be used before applying this command to introduce self-consistent quantum nuclear effects into the initial state.

The parameters \textit{q, mu, e0, p0, v0} and \textit{tscale} are described in the command \textit{fix msst}. The values of \textit{e0}, \textit{p0}, or \textit{v0} will be calculated on the first step if not specified. The parameter of \textit{damp, f_max}, and \textit{N_f} are described in the command \textit{fix qtb}.

The \textit{fix qbmsst} command couples the shock system to a quantum thermal bath with a rate that is proportional to the change of the total energy of the shock system, \(E_{\text{tot}} - E_{\text{tot}}^0\). Here \(E_{\text{tot}}\) consists of both the system energy and a thermal term, see \textit{(Qi)}, and \(E_{\text{tot}}^0 = e0\) is the initial total energy.

The \textit{eta (\eta)} parameter is a unitless coupling constant between the shock system and the quantum thermal bath. A small \(\eta\) value cannot adjust the quantum temperature fast enough during the temperature ramping period of shock compression while large \(\eta\) leads to big temperature oscillation. A value of \(\eta\) between 0.3 and 1 is usually appropriate for simulating most systems under shock compression. We observe that different values of \(\eta\) lead to almost the same final thermodynamic state behind the shock, as expected.

The quantum temperature is updated every \textit{beta (\beta)} steps with an integration time interval \(\beta\) times longer than the simulation time step. In that case, \(E_{\text{tot}}\) is taken as its average over the past \(\beta\) steps. The temperature of the quantum

Figure 2. Quantum temperature and pressure vs. time for simulating shocked \(\alpha\)-quartz with \textit{fix qbmsst}. The shock propagates along the \textit{z} direction. Restart of the \textit{fix qbmsst} command is demonstrated in the example input script. Thermodynamic quantities stay continuous before and after the restart.
LAMMPS Documentation, Release patch 23Jun2022

thermal bath $T^{qm}$ changes dynamically according to the following equation where $\Delta_t$ is the MD time step and $\gamma$ is the friction constant which is equal to the inverse of the $damp$ parameter.

$$\frac{dT^{qm}}{dt} = \gamma \eta \sum_{l=1}^{3} \frac{E^{tot}(t - l\Delta t) - E^{tot}}{3\beta N k_B}$$

The parameter $T_{init}$ is the initial temperature of the quantum thermal bath and the system before shock loading.

For all pressure styles, the simulation box stays orthorhombic in shape. Parrinello-Rahman boundary conditions (tilted box) are supported by LAMMPS, but are not implemented for QBMSST.

17.159.4 Restart, fix_modify, output, run start/stop, minimize info

Because the state of the random number generator is not written to binary restart files, this fix cannot be restarted “exactly” in an uninterrupted fashion. However, in a statistical sense, a restarted simulation should produce similar behaviors of the system as if it is not interrupted. To achieve such a restart, one should write explicitly the same value for $q$, $mu$, $damp$, $f_{max}$, $N_f$, $eta$, and $beta$ and set $tscale = 0$ if the system is compressed during the first run.

The cumulative energy change in the system imposed by this fix is included in the thermodynamic output keywords $ecouple$ and $econserve$. See the thermo_style doc page for details.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

The progress of the QBMSST can be monitored by printing the global scalar and global vector quantities computed by the fix.

As mentioned above, the scalar is the cumulative energy change due to the fix. By monitoring the thermodynamic $econserve$ output, this can be used to test if the MD timestep is sufficiently small for accurate integration of the dynamic equations.

The global vector contains five values in the following order. The vector values output by this fix are “intensive”.

$[d\text{hugoniot}, d\text{rayleigh}, l\text{agrangian\_speed}, l\text{agrangian\_position}, q\text{uantum\_temperature}]$

1. $d\text{hugoniot}$ is the departure from the Hugoniot (temperature units).
2. $d\text{rayleigh}$ is the departure from the Rayleigh line (pressure units).
3. $l\text{agrangian\_speed}$ is the laboratory-frame Lagrangian speed (particle velocity) of the computational cell (velocity units).
4. $l\text{agrangian\_position}$ is the computational cell position in the reference frame moving at the shock speed. This is the distance of the computational cell behind the shock front.
5. $q\text{uantum\_temperature}$ is the temperature of the quantum thermal bath $T^{qm}$.

To print these quantities to the log file with descriptive column headers, the following LAMMPS commands are suggested.

```lmp
double fix_id
fix_id 1.0 all msst z
fix_id 1.0 all variable dhug equal f_fix_id[1]
fix_id 1.0 all variable dray equal f_fix_id[2]
fix_id 1.0 all variable lgr_vel equal f_fix_id[3]
fix_id 1.0 all variable lgr_pos equal f_fix_id[4]
fix_id 1.0 all variable T_qm equal f_fix_id[5]
thermo_style custom step temp ke pe lz pzz econserve v_dhug v_dray v_lgr_vel v_lgr_pos v_T_qm f_fix_id
```
It is worth noting that the temp keyword for the `thermo_style` command prints the instantaneous classical temperature $T_{cl}$ as described by the `fix qtb` command.

### 17.159.5 Restrictions

This fix style is part of the QTB package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

All cell dimensions must be periodic. This fix can not be used with a triclinic cell. The QBMSST fix has been tested only for the group-ID all.

### 17.159.6 Related commands

`fix qtb`, `fix msst`

### 17.159.7 Default

The keyword defaults are $q = 10$, $mu = 0$, $tscale = 0.01$, $damp = 1$, $seed = 880302$, $f_{max} = 200.0$, $N_f = 100$, $eta = 1.0$, $beta = 100$, and $T_{init}=300.0$. $e_0$, $p_0$, and $v_0$ are calculated on the first step.

fix 1 qeq qeq/dynamic 1 12 1.0e-3 100 my_qeq
fix 1 all qeq/fire 1 10 1.0e-3 100 my_qeq qdamp 0.2 qstep 0.1
```

17.164.3 Description

Perform the charge equilibration (QEq) method as described in (Rappe and Goddard) and formulated in (Nakano) (also known as the matrix inversion method) and in (Rick and Stuart) (also known as the extended Lagrangian method) based on the electronegativity equilization principle.

These fixes can be used with any pair style in LAMMPS, so long as per-atom charges are defined. The most typical use-case is in conjunction with a pair style that performs charge equilibration periodically (e.g. every timestep), such as the ReaxFF or Streitz-Mintmire potential. But these fixes can also be used with potentials that normally assume per-atom charges are fixed, e.g. a Buckingham or LJ/Coulombic potential.

Because the charge equilibration calculation is effectively independent of the pair style, these fixes can also be used to perform a one-time assignment of charges to atoms. For example, you could define the QEq fix, perform a zero-timestep run via the run command without any pair style defined which would set per-atom charges (based on the current atom configuration), then remove the fix via the unfix command before performing further dynamics.

Note: Computing and using charge values different from published values defined for a fixed-charge potential like Buckingham or CHARMM or AMBER, can have a strong effect on energies and forces, and produces a different model than the published versions.

Note: The fix qeq/comb command must still be used to perform charge equilibration with the COMB potential. The fix qeq/reaxff command can be used to perform charge equilibration with the ReaxFF force field, although fix qeq/shielded
yields the same results as fix qeq/reaxff if Nevery, cutoff, and tolerance are the same. Eventually the fix qeq/reaxff command will be deprecated.

The QEq method minimizes the electrostatic energy of the system (or equalizes the derivative of energy with respect to charge of all the atoms) by adjusting the partial charge on individual atoms based on interactions with their neighbors within cutoff. It requires a few parameters in the appropriate units for each atom type which are read from a file specified by qfile. The file has the following format

<table>
<thead>
<tr>
<th></th>
<th>chi</th>
<th>eta</th>
<th>gamma</th>
<th>zeta</th>
<th>qcore</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>chi</td>
<td>eta</td>
<td>gamma</td>
<td>zeta</td>
<td>qcore</td>
</tr>
<tr>
<td>2</td>
<td>chi</td>
<td>eta</td>
<td>gamma</td>
<td>zeta</td>
<td>qcore</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Ntype</td>
<td>chi</td>
<td>eta</td>
<td>gamma</td>
<td>zeta</td>
<td>qcore</td>
</tr>
</tbody>
</table>

There have to be parameters given for every atom type. Wildcard entries are possible using the same type range syntax as for “coeff” commands (i.e., n*m, n*, *m, *). Later entries will overwrite previous ones. Empty lines or any text following the pound sign (#) are ignored. Each line starts with the atom type followed by five parameters. Only a subset of the parameters is used by each QEq style as described below, thus the others can be set to 0.0 if desired, but all five entries per line are required.

- **chi** = electronegativity in energy units
- **eta** = self-Coulomb potential in energy units
- **gamma** = shielded Coulomb constant defined by ReaxFF force field in distance units
- **zeta** = Slater type orbital exponent defined by the Streitz-Mintmire potential in reverse distance units
- **qcore** = charge of the nucleus defined by the Streitz-Mintmire potential in charge units

The fix qeq styles will print a warning if the charges are not equilibrated within tolerance by maxiter steps, unless the warn keyword is used with “no” as argument. This latter option may be useful for testing and benchmarking purposes, as it allows to use a fixed number of QEq iterations when tolerance is set to a small enough value to always reach the maxiter limit. Turning off warnings will avoid the excessive output in that case.

The qeq/point style describes partial charges on atoms as point charges. Interaction between a pair of charged particles is \(1/r\), which is the simplest description of the interaction between charges. Only the chi and eta parameters from the qfile file are used. Note that Coulomb catastrophe can occur if repulsion between the pair of charged particles is too weak. This style solves partial charges on atoms via the matrix inversion method. A tolerance of 1.0e-6 is usually a good number.

The qeq/shielded style describes partial charges on atoms also as point charges, but uses a shielded Coulomb potential to describe the interaction between a pair of charged particles. Interaction through the shielded Coulomb is given by equation (13) of the ReaxFF force field paper. The shielding accounts for charge overlap between charged particles at small separation. This style is the same as fix qeq/reaxff, and can be used with pair_style reaxff. Only the chi, eta, and gamma parameters from the qfile file are used. When using the string reaxff as filename, these parameters are extracted directly from an active reaxff pair style. This style solves partial charges on atoms via the matrix inversion method. A tolerance of 1.0e-6 is usually a good number.

The qeq/slater style describes partial charges on atoms as spherical charge densities centered around atoms via the Slater 1s orbital, so that the interaction between a pair of charged particles is the product of two Slater 1s orbitals. The expression for the Slater 1s orbital is given under equation (6) of the Streitz-Mintmire paper. Only the chi, eta, zeta, and qcore parameters from the qfile file are used. When using the string coul/streitz as filename, these parameters are extracted directly from an active coul/streitz pair style. This style solves partial charges on atoms via the matrix inversion method. A tolerance of 1.0e-6 is usually a good number. Keyword alpha can be used to change the Slater type orbital exponent.

The qeq/dynamic style describes partial charges on atoms as point charges that interact through \(1/r\), but the extended Lagrangian method is used to solve partial charges on atoms. Only the chi and eta parameters from the qfile file are used. Note that Coulomb catastrophe can occur if repulsion between the pair of charged particles is too weak. A tolerance of
1.0e-3 is usually a good number. Keyword \textit{qdamp} can be used to change the damping factor, while keyword \textit{qstep} can be used to change the time step size.

The \textit{*qeq/fire*} style describes the same charge model and charge solver as the \textit{qeq/dynamic} style, but employs a FIRE minimization algorithm to solve for equilibrium charges. Keyword \textit{qdamp} can be used to change the damping factor, while keyword \textit{qstep} can be used to change the time step size.

Note that \textit{qeq/point}, \textit{qeq/shielded}, and \textit{qeq/slater} describe different charge models, whereas the matrix inversion method and the extended Lagrangian method (\textit{qeq/dynamic} and \textit{qeq/fire}) are different solvers.

Note that \textit{qeq/point}, \textit{qeq/dynamic} and \textit{qeq/fire} styles all describe charges as point charges that interact through 1/r relationship, but solve partial charges on atoms using different solvers. These three styles should yield comparable results if the QEq parameters and \textit{Nevery}, \textit{cutoff}, and \textit{tolerance} are the same. Style \textit{qeq/point} is typically faster, \textit{qeq/dynamic} scales better on larger sizes, and \textit{qeq/fire} is faster than \textit{qeq/dynamic}.

\textbf{Note:} In order to solve the self-consistent equations for electronegativity equalization, LAMMPS imposes the additional constraint that all the charges in the fix group must add up to zero. The initial charge assignments should also satisfy this constraint. LAMMPS will print a warning if that is not the case.

\textbf{Note:} Developing QEq parameters (chi, eta, gamma, zeta, and qcore) is non-trivial. Charges on atoms are not guaranteed to equilibrate with arbitrary choices of these parameters. We do not develop these QEq parameters. See the examples/qeq directory for some examples.

17.164.4 Restart, fix\_modify, output, run start/stop, minimize info

No information about these fixes is written to binary restart files. No global scalar or vector or per-atom quantities are stored by these fixes for access by various output commands. No parameter of these fixes can be used with the \textit{start/stop} keywords of the \textit{run} command.

These fixes are invoked during energy minimization.

17.164.5 Restrictions

These fixes are part of the QEQ package. They are only enabled if LAMMPS was built with that package. See the \textit{Build package} page for more info.

These qeq fixes are not compatible with the GPU and USER-INTEL packages.

These qeq fixes will ignore electric field contributions from \textit{fix efield}.

17.165.2 Examples

fix 1 surface qeq/comb 10 0.0001

17.165.3 Description

Perform charge equilibration (QeQ) in conjunction with the COMB (Charge-Optimized Many-Body) potential as described in (COMB_1) and (COMB_2). It performs the charge equilibration portion of the calculation using the so-called QEq method, whereby the charge on each atom is adjusted to minimize the energy of the system. This fix can only be used with the COMB potential; see the fix qeq/reaxff command for a QeQ calculation that can be used with any potential.

Only charges on the atoms in the specified group are equilibrated. The fix relies on the pair style (COMB in this case) to calculate the per-atom electronegativity (effective force on the charges). An electronegativity equalization calculation
(or QEq) is performed in an iterative fashion, which in parallel requires communication at each iteration for processors to exchange charge information about nearby atoms with each other. See Rappe_and_Goddard and Rick_and_Stuart for details.

During a run, charge equilibration is performed every Nevery time steps. Charge equilibration is also always enforced on the first step of each run. The precision argument controls the tolerance for the difference in electronegativity for all atoms during charge equilibration. Precision is a trade-off between the cost of performing charge equilibration (more iterations) and accuracy.

If the file keyword is used, then information about each equilibration calculation is written to the specified file.

---

**Note:** In order to solve the self-consistent equations for electronegativity equalization, LAMMPS imposes the additional constraint that all the charges in the fix group must add up to zero. The initial charge assignments should also satisfy this constraint. LAMMPS will print a warning if that is not the case.

---

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 17.165.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is performing charge equilibration. Default is the outermost level.

This fix produces a per-atom vector which can be accessed by various output commands. The vector stores the gradient of the charge on each atom. The per-atom values be accessed on any timestep.

No parameter of this fix can be used with the start/stop keywords of the run command.

This fix can be invoked during energy minimization.

### 17.165.5 Restrictions

This fix command currently only supports pair style *comb*.
17.165.6 Related commands

pair_style comb

17.165.7 Default

17.166 fix qeq/reaxff command

Accelerator Variants: qeq/reaxff/kk, qeq/reaxff/omp

17.166.1 Syntax

<table>
<thead>
<tr>
<th>fix ID group-ID qeq/reaxff Nevery cutlo cuthi tolerance params args</th>
</tr>
</thead>
<tbody>
<tr>
<td>• ID, group-ID are documented in fix command</td>
</tr>
<tr>
<td>• qeq/reaxff = style name of this fix command</td>
</tr>
<tr>
<td>• Nevery = perform QEq every this many steps</td>
</tr>
<tr>
<td>• cutlo,cuthi = lo and hi cutoff for Taper radius</td>
</tr>
<tr>
<td>• tolerance = precision to which charges will be equilibrated</td>
</tr>
<tr>
<td>• params = reaxff or a filename</td>
</tr>
<tr>
<td>• one or more keywords or keyword/value pairs may be appended</td>
</tr>
</tbody>
</table>

keyword = dual or maxiter or nowarn

dual = process S and T matrix in parallel (only for qeq/reaxff/omp)
maxiter N = limit the number of iterations to N
nowarn = do not print a warning message if the maximum number of iterations was reached

17.166.2 Examples

```
fix 1 all qeq/reaxff 1 0.0 10.0 1.0e-6 reaxff
fix 1 all qeq/reaxff 1 0.0 10.0 1.0e-6 param.qeq maxiter 500
```
17.166.3 Description

Perform the charge equilibration (QEq) method as described in (Rappe and Goddard) and formulated in (Nakano). It is typically used in conjunction with the ReaxFF force field model as implemented in the pair_style reaxff command, but it can be used with any potential in LAMMPS, so long as it defines and uses charges on each atom. The fix qeq/comb command should be used to perform charge equilibration with the COMB potential. For more technical details about the charge equilibration performed by fix qeq/reaxff, see the (Aktulga) paper.

The QEq method minimizes the electrostatic energy of the system by adjusting the partial charge on individual atoms based on interactions with their neighbors. It requires some parameters for each atom type. If the params setting above is the word “reaxff”, then these are extracted from the pair_style reaxff command and the ReaxFF force field file it reads in. If a file name is specified for params, then the parameters are taken from the specified file and the file must contain one line for each atom type. The latter form must be used when performing QEq with a non-ReaxFF potential. Each line should be formatted as follows:

<table>
<thead>
<tr>
<th>itype</th>
<th>chi</th>
<th>eta</th>
<th>gamma</th>
</tr>
</thead>
</table>

where itype is the atom type from 1 to Ntypes, chi denotes the electronegativity in eV, eta denotes the self-Coulomb potential in eV, and gamma denotes the valence orbital exponent. Note that these 3 quantities are also in the ReaxFF potential file, except that eta is defined here as twice the eta value in the ReaxFF file. Note that unlike the rest of LAMMPS, the units of this fix are hard-coded to be Å, eV, and electronic charge.

The optional dual keyword allows to perform the optimization of the S and T matrices in parallel. This is only supported for the qeq/reaxff/omp style. Otherwise they are processed separately. The qeq/reaxff/kk style always solves the S and T matrices in parallel.

The optional maxiter keyword allows changing the max number of iterations in the linear solver. The default value is 200.

The optional nowarn keyword silences the warning message printed when the maximum number of iterations was reached. This can be useful for comparing serial and parallel results where having the same fixed number of QEq iterations is desired, which can be achieved by using a very small tolerance and setting maxiter to the desired number of iterations.

**Note:** In order to solve the self-consistent equations for electronegativity equalization, LAMMPS imposes the additional constraint that all the charges in the fix group must add up to zero. The initial charge assignments should also satisfy this constraint. LAMMPS will print a warning if that is not the case.

17.166.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. This fix computes a global scalar (the number of iterations) for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command.

This fix is invoked during energy minimization.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.
You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

17.166.5 Restrictions

This fix is part of the REAXFF package. It is only enabled if LAMMPS was built with that package. See the Build page for more info.

This fix does not correctly handle interactions involving multiple periodic images of the same atom. Hence, it should not be used for periodic cell dimensions less than 10 angstroms.

This fix may be used in combination with `fix efield` and will apply the external electric field during charge equilibration, but there may be only one fix efield instance used, it may only use a constant electric field, and the electric field vector may only have components in non-periodic directions.

17.166.6 Related commands

`pair_style reaxff`, `fix qeq/shielded`

17.166.7 Default

maxiter 200

17.167 fix qmmm command

17.167.1 Syntax

```
fix ID group-ID qmmm
```

- ID, group-ID are documented in `fix` command
- qmmm = style name of this fix command
17.167.2 Examples

```plaintext
fix 1 qmol qmmm
```

17.167.3 Description

This fix provides functionality to enable a quantum mechanics/molecular mechanics (QM/MM) coupling of LAMMPS to a quantum mechanical code. The current implementation only supports an ONIOM style mechanical coupling to the Quantum ESPRESSO plane wave DFT package. Electrostatic coupling is in preparation and the interface has been written in a manner that coupling to other QM codes should be possible without changes to LAMMPS itself.

The interface code for this is in the lib/qmmm directory of the LAMMPS distribution and is being made available at this early stage of development in order to encourage contributions for interfaces to other QM codes. This will allow the LAMMPS side of the implementation to be adapted if necessary before being finalized.

Details about how to use this fix are currently documented in the description of the QM/MM interface code itself in lib/qmmm/README.

17.167.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global scalar or vector or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.167.5 Restrictions

This fix is part of the QMMM package. It is only enabled if LAMMPS was built with that package. It also requires building a library provided with LAMMPS. See the Build package page for more info.

The fix is only functional when LAMMPS is built as a library and linked with a compatible QM program and a QM/MM front end into a QM/MM executable. See the lib/qmmm/README file for details.

17.168 fix qtb command

17.168.1 Syntax

```
fix ID group-ID qtb keyword value ...
```

- ID, group-ID are documented in `fix` command
- `qtb` = style name of this fix
- zero or more keyword/value pairs may be appended
- keyword = `temp` or `damp` or `seed` or `f_max` or `N_f`
  
  - `temp` value = target quantum temperature (temperature units)
  - `damp` value = damping parameter (time units) inverse of friction $\gamma$
  - `seed` value = random number seed (positive integer)
  - `f_max` value = upper cutoff frequency of the vibration spectrum (1/time units)
  - `N_f` value = number of frequency bins (positive integer)

17.168.2 Examples

```latex
# (liquid methane modeled with the REAX force field, real units)
fix 1 all nve
fix 1 all qtb temp 110 damp 200 seed 35082 f_max 0.3 N_f 100
# (quartz modeled with the BKS force field, metal units)
fix 2 all nph iso 1.01325 1.01325 1
fix 2 all qtb temp 300 damp 1 seed 47508 f_max 120.0 N_f 100
```

17.168.3 Description

This command performs the quantum thermal bath scheme proposed by (Dammak) to include self-consistent quantum nuclear effects, when used in conjunction with the `fix nve` or `fix nph` commands.

Classical molecular dynamics simulation does not include any quantum nuclear effect. Quantum treatment of the vibrational modes will introduce zero point energy into the system, alter the energy power spectrum and bias the heat capacity from the classical limit. Missing all the quantum nuclear effects, classical MD cannot model systems at temperatures lower than their classical limits. This effect is especially important for materials with a large population of hydrogen atoms and thus higher classical limits.

The equation of motion implemented by this command follows a Langevin form:

$$m_i a_i = f_i + R_i - m_i \gamma v_i$$

Here $m_i$, $a_i$, $f_i$, $R_i$, $\gamma$, and $v_i$ represent in this order mass, acceleration, force exerted by all other atoms, random force, frictional coefficient (the inverse of damping parameter `damp`), and velocity. The random force $R_i$ is “colored” so that any vibrational mode with frequency $\omega$ will have a temperature-sensitive energy $\theta(\omega; T)$ which resembles the energy expectation for a quantum harmonic oscillator with the same natural frequency:

$$\theta(\omega T) = \frac{\hbar}{2} + \hbar \omega \left[ \exp\left(\frac{\hbar \omega}{k_B T}\right) - 1 \right]^{-1}$$

To efficiently generate the random forces, we employ the method of (Barrat), that circumvents the need to generate all random forces for all times before the simulation. The memory requirement of this approach is less demanding.
and independent of the simulation duration. Since the total random force $R_{tot}$ does not necessarily vanish for a finite number of atoms, $R_i$ is replaced by $R_i - \frac{\Delta t}{R_{tot}}$ to avoid collective motion of the system.

The *temp* parameter sets the target quantum temperature. LAMMPS will still have an output temperature in its thermo style. That is the instantaneous classical temperature $T^{cl}$ derived from the atom velocities at thermal equilibrium. A non-zero $T^{cl}$ will be present even when the quantum temperature approaches zero. This is associated with zero-point energy at low temperatures.

$$T^{cl} = \sum \frac{m_i v_i^2}{3Nk_B}$$

The *damp* parameter is specified in time units, and it equals the inverse of the frictional coefficient $\gamma$. $\gamma$ should be as small as possible but slightly larger than the timescale of anharmonic coupling in the system which is about 10 ps to 100 ps. When $\gamma$ is too large, it gives an energy spectrum that differs from the desired Bose-Einstein spectrum. When $\gamma$ is too small, the quantum thermal bath coupling to the system will be less significant than anharmonic effects, reducing to a classical limit. We find that setting $\gamma$ between 5 THz and 1 THz could be appropriate depending on the system.

The random number *seed* is a positive integer used to initiate a Marsaglia random number generator. Each processor uses the input seed to generate its own unique seed and its own stream of random numbers. Thus the dynamics of the system will not be identical on two runs on different numbers of processors.

The *f_max* parameter truncate the noise frequency domain so that vibrational modes with frequencies higher than *f_max* will not be modulated. If we denote $\Delta t$ as the time interval for the MD integration, *f_max* is always reset by the code to make $\alpha = (\text{int})(2f_{\text{max}} \Delta t)^{-1}$ a positive integer and print out relative information. An appropriate value for the cutoff frequency *f_max* would be around 2~3 $f_D$, where $f_D$ is the Debye frequency.

The *N_f* parameter is the frequency grid size, the number of points from 0 to *f_max* in the frequency domain that will be sampled. 3*2*N_f* per-atom random numbers are required in the random force generation and there could be as many atoms as in the whole simulation that can migrate into every individual processor. A larger *N_f* provides a more accurate sampling of the spectrum while consumes more memory. With fixed *f_max* and $\gamma$, *N_f* should be big enough to converge the classical temperature $T^{cl}$ as a function of target quantum bath temperature. Memory usage per processor could be from 10 to 100 MBytes.

**Note:** Unlike the *fix nvt* command which performs Nose/Hoover thermostatting AND time integration, this fix does NOT perform time integration. It only modifies forces to a colored thermostat. Thus you must use a separate time integration fix, like *fix nve* or *fix nph* to actually update the velocities and positions of atoms (as shown in the examples). Likewise, this fix should not normally be used with other fixes or commands that also specify system temperatures, e.g. *fix nvt* and *fix temp/rescale*.

### 17.168.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. Because the state of the random number generator is not saved in restart files, this means you cannot do “exact” restarts with this fix. However, in a statistical sense, a restarted simulation should produce similar behaviors of the system.

This fix is not invoked during *energy minimization*.
17.168.5 Restrictions

This fix style is part of the QTB package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

17.168.6 Related commands

fix nve, fix nph, fix langevin, fix qbmsst

17.168.7 Default

The keyword defaults are temp = 300, damp = 1, seed = 880302, f_max=200.0 and N_f = 100.

17.169 fix reaxff/bonds command

Accelerator Variants: reaxff/bonds/kk

17.169.1 Syntax

```
fix ID group-ID reaxff/bonds Nevery filename
```

- ID, group-ID are documented in fix command
- reax/bonds = style name of this fix command
- Nevery = output interval in timesteps
- filename = name of output file

17.169.2 Examples

```
fix 1 all reaxff/bonds 100 bonds.reaxff
```
17.169.3 Description

Write out the bond information computed by the ReaxFF potential specified by `pair_style reaxff` in the exact same format as the original stand-alone ReaxFF code of Adri van Duin. The bond information is written to `filename` on timesteps that are multiples of `Nevery`, including timestep 0. For time-averaged chemical species analysis, please see the `fix reaxff/species` command.

The specified group-ID is ignored by this fix.

The format of the output file should be reasonably self-explanatory. The meaning of the column header abbreviations is as follows:

- `id` = atom id
- `type` = atom type
- `nb` = number of bonds
- `id_1` = atom id of first bond
- `id_nb` = atom id of Nth bond
- `mol` = molecule id
- `bo_1` = bond order of first bond
- `bo_nb` = bond order of Nth bond
- `abo` = atom bond order (sum of all bonds)
- `nlp` = number of lone pairs
- `q` = atomic charge

If the filename ends with “.gz”, the output file is written in gzipped format. A gzipped dump file will be about 3x smaller than the text version, but will also take longer to write.

17.169.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the `fix_modify` options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during energy minimization.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
17.169.5 Restrictions

The fix reaxff/bonds command requires that the pair_style reaxff is invoked. This fix is part of the REAXFF package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

To write gzipped bond files, you must compile LAMMPS with the -DLAMMPS_GZIP option.

- ID, group-ID are documented in fix command
- reaxff/species = style name of this command
- Nevery = sample bond-order every this many timesteps
- Nrepeat = # of bond-order samples used for calculating averages
- Nfreq = calculate average bond-order every this many timesteps
- filename = name of output file
- zero or more keyword/value pairs may be appended
- keyword = cutoff or element or position

  cutoff value = I J Cutoff
  I, J = atom types
  Cutoff = Bond-order cutoff value for this pair of atom types

  element value = Element1, Element2, ...

  position value = posfreq filepos
  posfreq = write position files every this many timestep
  filepos = name of position output file
17.170.2 Examples

```plaintext
fix 1 all reaxff/species 10 10 100 species.out
fix 1 all reaxff/species 1 2 20 species.out cutoff 1 1 0.40 cutoff 1 2 0.55
fix 1 all reaxff/species 1 100 100 species.out element Au O H position 1000 AuOH.pos
```

17.170.3 Description

Write out the chemical species information computed by the ReaxFF potential specified by `pair_style reaxff`. Bond-order values (either averaged or instantaneous, depending on value of `Nrepeat`) are used to determine chemical bonds. Every `Nfreq` timesteps, chemical species information is written to `filename` as a two line output. The first line is a header containing labels. The second line consists of the following: timestep, total number of molecules, total number of distinct species, number of molecules of each species. In this context, “species” means a unique molecule. The chemical formula of each species is given in the first line.

**Warning:** In order to compute averaged data, it is required that there are no neighbor list rebuilds between the `Nfreq` steps. For that reason, `fix reaxff/species` may change your neighbor list settings. There will be a warning message showing the new settings. Having an `Nfreq` setting that is larger than what is required for correct computation of the ReaxFF force field interactions can thus lead to incorrect results. For typical ReaxFF calculations a value of 100 is already quite large.

If the filename ends with “.gz”, the output file is written in gzipped format. A gzipped dump file will be about 3x smaller than the text version, but will also take longer to write.

Optional keyword `cutoff` can be assigned to change the minimum bond-order values used in identifying chemical bonds between pairs of atoms. Bond-order cutoffs should be carefully chosen, as bond-order cutoffs that are too small may include too many bonds (which will result in an error), while cutoffs that are too large will result in fragmented molecules. The default cutoff of 0.3 usually gives good results.

The optional keyword `element` can be used to specify the chemical symbol printed for each LAMMPS atom type. The number of symbols must match the number of LAMMPS atom types and each symbol must consist of 1 or 2 alphanumeric characters. Normally, these symbols should be chosen to match the chemical identity of each LAMMPS atom type, as specified using the `reaxff pair_coeff` command and the ReaxFF force field file.

The optional keyword `position` writes center-of-mass positions of each identified molecules to file `filepos` every `posfreq` timesteps. The first line contains information on timestep, total number of molecules, total number of distinct species, and box dimensions. The second line is a header containing labels. From the third line downward, each molecule writes a line of output containing the following information: molecule ID, number of atoms in this molecule, chemical formula, total charge, and center-of-mass xyz positions of this molecule. The xyz positions are in fractional coordinates relative to the box dimensions.

For the keyword `position`, the `filepos` is the name of the output file. It can contain the wildcard character “*”. If the “*” character appears in `filepos`, then one file per snapshot is written at `posfreq` and the “*” character is replaced with the timestep value. For example, `AuO.pos.*` becomes `AuO.pos.0, AuO.pos.1000, etc.

The `Nevery`, `Nrepeat`, and `Nfreq` arguments specify on what timesteps the bond-order values are sampled to get the average bond order. The species analysis is performed using the average bond-order on timesteps that are a multiple of `Nfreq`. The average is over `Nrepeat` bond-order samples, computed in the preceding portion of the simulation every `Nevery` timesteps. `Nfreq` must be a multiple of `Nevery` and `Nevery` must be non-zero even if `Nrepeat` is 1. Also, the timesteps contributing to the average bond-order cannot overlap, i.e. `Nrepeat*Nevery` can not exceed `Nfreq`.

For example, if `Nevery=2, Nrepeat=6`, and `Nfreq=100`, then bond-order values on timesteps 90,92,94,96,98,100 will be used to compute the average bond-order for the species analysis output on timestep 100.
17.170.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. This fix computes both a global vector of length 2 and a per-atom vector, either of which can be accessed by various output commands. The values in the global vector are “intensive”.

The 2 values in the global vector are as follows:

• 1 = total number of molecules
• 2 = total number of distinct species

The per-atom vector stores the molecule ID for each atom as identified by the fix. If an atom is not in a molecule, its ID will be 0. For atoms in the same molecule, the molecule ID for all of them will be the same and will be equal to the smallest atom ID of any atom in the molecule.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

17.170.5 Restrictions

The “fix reaxff/species” requires that pair_style reaxff is used. This fix is part of the REAXFF package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

To write gzipped species files, you must compile LAMMPS with the -DLAMMPS_GZIP option.

17.170.6 Related commands

pair_style reaxff, fix reaxff/bonds

The default values for bond-order cutoffs are 0.3 for all I-J pairs. The default element symbols are C, H, O, N. Position files are not written by default.

17.171 fix recenter command

17.171.1 Syntax

```
fix ID group-ID recenter x y z keyword value ...
```

- ID, group-ID are documented in `fix` command
- recenter = style name of this fix command
- x,y,z = constrain center-of-mass to these coords (distance units), any coord can also be NULL or INIT (see below)
- zero or more keyword/value pairs may be appended
- keyword = `shift` or `units`
  - `shift` value = group-ID
  - `units` value = group of atoms whose coords are shifted
  - `units` value = box or lattice or fraction

17.171.2 Examples

```
fix 1 all recenter 0.0 0.5 0.0
fix 1 all recenter INIT INIT NULL
fix 1 all recenter INIT 0.0 0.0 units box
```

17.171.3 Description

Constrain the center-of-mass position of a group of atoms by adjusting the coordinates of the atoms every timestep. This is simply a small shift that does not alter the dynamics of the system or change the relative coordinates of any pair of atoms in the group. This can be used to insure the entire collection of atoms (or a portion of them) do not drift during the simulation due to random perturbations (e.g. `fix langevin` thermostatting).

Distance units for the x,y,z values are determined by the setting of the `units` keyword, as discussed below. One or more x,y,z values can also be specified as NULL, which means exclude that dimension from this operation. Or it can be specified as INIT which means to constrain the center-of-mass to its initial value at the beginning of the run.

The center-of-mass (COM) is computed for the group specified by the fix. If the current COM is different than the specified x,y,z, then a group of atoms has their coordinates shifted by the difference. By default the shifted group is also the group specified by the fix. A different group can be shifted by using the `shift` keyword. For example, the COM could be computed on a protein to keep it in the center of the simulation box. But the entire system (protein + water) could be shifted.

If the `units` keyword is set to `box`, then the distance units of x,y,z are defined by the `units` command - e.g. Angstroms for `real` units. A `lattice` value means the distance units are in lattice spacings. The `lattice` command must have been previously used to define the lattice spacings. A `fraction` value means a fractional distance between the lo/hi box boundaries, e.g. 0.5 = middle of the box. The default is to use lattice units.

Note that the `velocity` command can be used to create velocities with zero aggregate linear and/or angular momentum.
**Note:** This fix performs its operations at the same point in the timestep as other time integration fixes, such as `fix nve, fix nvt, or fix npt`. Thus fix recenter should normally be the last such fix specified in the input script, since the adjustments it makes to atom coordinates should come after the changes made by time integration. LAMMPS will warn you if your fixes are not ordered this way.

**Note:** If you use this fix on a small group of atoms (e.g. a molecule in solvent) without using the `shift` keyword to adjust the positions of all atoms in the system, then the results can be unpredictable. For example, if the molecule is pushed consistently in one direction by a flowing solvent, its velocity will increase. But its coordinates will be re-centered, meaning it is moved back towards the force. Thus over time, the velocity and effective temperature of the molecule could become very large, though it won’t actually be moving due to the re-centering. If you are thermostatting the entire system, then the solvent would be cooled to compensate. A better solution for this simulation scenario is to use the `fix spring` command to tether the molecule in place.

### 17.171.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the `fix_modify` options are relevant to this fix. This fix computes a global scalar which can be accessed by various `output commands`. The scalar is the distance the group is moved by fix recenter.

This fix also computes global 3-vector which can be accessed by various `output commands`. The 3 quantities in the vector are xyz components of displacement applied to the group of atoms by the fix.

The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during energy minimization.

### 17.171.5 Restrictions

This fix should not be used with an x,y,z setting that causes a large shift in the system on the first timestep, due to the requested COM being very different from the initial COM. This could cause atoms to be lost, especially in parallel. Instead, use the `displace_atoms` command, which can be used to move atoms a large distance.

### 17.171.6 Related commands

`fix momentum, velocity`

### 17.171.7 Default

The option defaults are shift = fix group-ID, and units = lattice.
17.172 fix restrain command

17.172.1 Syntax

```plaintext
fix ID group-ID restrain keyword args ...  
```

- ID, group-ID are documented in `fix` command
- `restrain` = style name of this fix command
- one or more keyword/arg pairs may be appended
- `keyword = bond or lbound or angle or dihedral`

**bond** args = atom1 atom2 Kstart Kstop r0start (r0stop)
- atom1, atom2 = IDs of 2 atoms in bond
- Kstart, Kstop = restraint coefficients at start/end of run (energy units)
- r0start = equilibrium bond distance at start of run (distance units)
- r0stop = equilibrium bond distance at end of run (optional) (distance units). If not specified it is assumed to be equal to r0start

**lbound** args = atom1 atom2 Kstart Kstop r0start (r0stop)
- atom1, atom2 = IDs of 2 atoms in bond
- Kstart, Kstop = restraint coefficients at start/end of run (energy units)
- r0start = equilibrium bond distance at start of run (distance units)
- r0stop = equilibrium bond distance at end of run (optional) (distance units). If not specified it is assumed to be equal to r0start

**angle** args = atom1 atom2 atom3 Kstart Kstop theta0
- atom1, atom2, atom3 = IDs of 3 atoms in angle, atom2 = middle atom
- Kstart, Kstop = restraint coefficients at start/end of run (energy units)
- theta0 = equilibrium angle theta (degrees)

**dihedral** args = atom1 atom2 atom3 atom4 Kstart Kstop phi0 keyword/value
- atom1, atom2, atom3, atom4 = IDs of 4 atoms in dihedral in linear order
- Kstart, Kstop = restraint coefficients at start/end of run (energy units)
- phi0 = equilibrium dihedral angle phi (degrees)
- keyword/value = optional keyword value pairs. Supported keyword/value pairs:
  - `mult n = dihedral multiplicity n` (integer >= 0, default = 1)

17.172.2 Examples

```plaintext
fix holdem all restrain bond 45 48 2000.0 2000.0 2.75
fix holdem all restrain lbound 45 48 2000.0 2000.0 2.75
fix holdem all restrain dihedral 1 2 3 4 2000.0 2000.0 120.0
fix holdem all restrain bond 45 48 2000.0 2000.0 2.75 dihedral 1 2 3 4 2000.0 2000.0 120.0 0
fix texas_holdem all restrain dihedral 1 2 3 4 0.0 2000.0 120.0 dihedral 1 2 3 5 0.0 2000.0 -120.0 dihedral 1 2 3 6 0.0 2000.0 0.0
```
17.172.3 Description

Restrain the motion of the specified sets of atoms by making them part of a bond or angle or dihedral interaction whose strength can vary over time during a simulation. This is functionally similar to creating a bond or angle or dihedral for the same atoms in a data file, as specified by the `read_data` command, albeit with a time-varying prefactor coefficient, and except for exclusion rules, as explained below.

For the purpose of force field parameter-fitting or mapping a molecular potential energy surface, this fix reduces the hassle and risk associated with modifying data files. In other words, use this fix to temporarily force a molecule to adopt a particular conformation. To create a permanent bond or angle or dihedral, you should modify the data file.

**Note:** Adding a bond/angle/dihedral with this command does not apply the exclusion rules and weighting factors specified by the `special_bonds` command to atoms in the restraint that are now bonded (1-2,1-3,1-4 neighbors) as a result. If they are close enough to interact in a `pair_style` sense (non-bonded interaction), then the bond/angle/dihedral restraint interaction will simply be superposed on top of that interaction.

The group-ID specified by this fix is ignored.

The second example above applies a restraint to hold the dihedral angle formed by atoms 1, 2, 3, and 4 near 120 degrees using a constant restraint coefficient. The fourth example applies similar restraints to multiple dihedral angles using a restraint coefficient that increases from 0.0 to 2000.0 over the course of the run.

**Note:** Adding a force to atoms implies a change in their potential energy as they move due to the applied force field. For dynamics via the `run` command, this energy can be added to the system’s potential energy for thermodynamic output (see below). For energy minimization via the `minimize` command, this energy must be added to the system’s potential energy to formulate a self-consistent minimization problem (see below).

In order for a restraint to be effective, the restraint force must typically be significantly larger than the forces associated with conventional force field terms. If the restraint is applied during a dynamics run (as opposed to during an energy minimization), a large restraint coefficient can significantly reduce the stable timestep size, especially if the atoms are initially far from the preferred conformation. You may need to experiment to determine what value of $K$ works best for a given application.

For the case of finding a minimum energy structure for a single molecule with particular restraints (e.g. for fitting force field parameters or constructing a potential energy surface), commands such as the following may be useful:

```
# minimize molecule energy with restraints
velocity all create 600.0 8675309 mom yes rot yes dist gaussian
fix NVE all nve
fix TFIX all langevin 600.0 0.0 100 24601
fix REST all restrain dihedral 2 1 3 0.0 5000.0 ${angle1} dihedral 3 1 2 9 0.0 5000.0
fix_modify REST energy yes
run 10000
fix TFIX all langevin 0.0 0.0 100 24601
fix REST all restrain dihedral 2 1 3 5000.0 5000.0 ${angle1} dihedral 3 1 2 9 5000.0
      .5000.0 ${angle2}
fix_modify REST energy yes
run 10000
# sanity check for convergence
minimize 1e-6 1e-9 1000 100000
# report unrestrained energies
```
(continues on next page)
The `bond` keyword applies a bond restraint to the specified atoms using the same functional form used by the `bond_style harmonic` command. The potential associated with the restraint is

\[ E = K(r - r_0)^2 \]

with the following coefficients:

- \( K \) (energy/distance^2)
- \( r_0 \) (distance)

\( K \) and \( r_0 \) are specified with the fix. Note that the usual 1/2 factor is included in \( K \).

The `lbound` keyword applies a lower bound bond restraint to the specified atoms using the same functional form used by the `bond_style harmonic` command if the distance between the atoms is smaller than the equilibrium bond distance and 0 otherwise. The potential associated with the restraint is

\[ E = \begin{cases} K(r - r_0)^2, & \text{if } r < r_0 \\ 0, & \text{if } r \geq r_0 \end{cases} \]

with the following coefficients:

- \( K \) (energy/distance^2)
- \( r_0 \) (distance)

\( K \) and \( r_0 \) are specified with the fix. Note that the usual 1/2 factor is included in \( K \).

The `angle` keyword applies an angle restraint to the specified atoms using the same functional form used by the `angle_style harmonic` command. The potential associated with the restraint is

\[ E = K(\theta - \theta_0)^2 \]

with the following coefficients:

- \( K \) (energy)
- \( \theta_0 \) (degrees)

\( K \) and \( \theta_0 \) are specified with the fix. \( \theta_0 \) is specified in degrees, but LAMMPS converts it to radians internally; hence \( K \) is effectively energy per radian^2. Note that the usual 1/2 factor is included in \( K \).

The `dihedral` keyword applies a dihedral restraint to the specified atoms using a simplified form of the function used by the `dihedral_style charmm` command. The potential associated with the restraint is

\[ E = K[1 + \cos(n\phi - d)] \]

with the following coefficients:

- \( K \) (energy)
• \( n \) (multiplicity, \( \geq 0 \))
• \( d \) (degrees) = \( \phi_0 + 180 \)

\( K \) and \( \phi_0 \) are specified with the fix. Note that the value of the dihedral multiplicity \( n \) is set by default to 1. You can use the optional \textit{mult} keyword to set it to a different positive integer. Also note that the energy will be a minimum when the current dihedral angle \( \phi \) is equal to \( \phi_0 \).

### 17.172.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to \textit{binary restart files}.

The \texttt{fix_modify energy} option is supported by this fix to add the potential energy associated with this fix to the global potential energy of the system as part of \textit{thermodynamic output}. The default setting for this fix is \texttt{fix_modify energy no}.

The \texttt{fix_modify respa} option is supported by this fix. This allows to set at which level of the \textit{r-RESPA} integrator the fix is adding its forces. Default is the outermost level.

**Note:** If you want the fictitious potential energy associated with the added forces to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the \texttt{fix_modify energy} option for this fix.

This fix computes a global scalar and a global vector of length 3, which can be accessed by various \textit{output commands}. The scalar is the total potential energy for \textit{all} the restraints as discussed above. The vector values are the sum of contributions to the following individual categories:

• 1 = bond energy
• 2 = angle energy
• 3 = dihedral energy

The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the \texttt{start/stop} keywords of the \texttt{run} command.

### 17.172.5 Restrictions

none

### 17.172.6 Related commands

### 17.172.7 Default

none
17.173 fix rhok command

17.173.1 Syntax

```plaintext
fix ID group-ID rhok nx ny nz K a
```

- ID, group-ID are documented in `fix` command
- `nx, ny, nz` = k-vector of collective density field
- `K` = spring constant of bias potential
- `a` = anchor point of bias potential

17.173.2 Examples

```plaintext
fix bias all rhok 16 0 0 4.0 16.0
fix 1 all npt temp 0.8 0.8 4.0 z 2.2 2.2 8.0
# output of 4 values from fix rhok: U_bias rho_k_RE rho_k_IM \|rho_k\|
```

17.173.3 Description

The fix applies a force to atoms given by the potential

\[
U = \frac{1}{2} K (|\rho_{\vec{k}}| - a)^2
\]

\[
\rho_{\vec{k}} = \sum_j^N \exp(-i\vec{k} \cdot \vec{r}_j)/\sqrt{N}
\]

\[
\vec{k} = (2\pi n_x / L_x, 2\pi n_y / L_y, 2\pi n_z / L_z)
\]

as described in (Pedersen).

This field, which biases configurations with long-range order, can be used to study crystal-liquid interfaces and determine melting temperatures (Pedersen).

An example of using the interface pinning method is located in the `examples/PACKAGES/rhok` directory.

17.173.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to `binary restart files`.

The `fix_modify energy` option is supported by this fix to add the potential energy calculated by the fix to the global potential energy of the system as part of `thermodynamic output`. The default setting for this fix is `fix_modify energy no`.

This fix computes a global scalar which can be accessed by various `output commands`. The scalar is the potential energy discussed in the preceding paragraph. The scalar stored by this fix is “extensive”.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command.

This fix is not invoked during `energy minimization`. 
17.173.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

17.183.3 Description

Treat one or more sets of atoms as independent rigid bodies. This means that each timestep the total force and torque on each rigid body is computed as the sum of the forces and torques on its constituent particles. The coordinates, velocities, and orientations of the atoms in each body are then updated so that the body moves and rotates as a single entity. This is implemented by creating internal data structures for each rigid body and performing time integration on these data structures. Positions, velocities, and orientations of the constituent particles are regenerated from the rigid body data structures in every time step. This restricts which operations and fixes can be applied to rigid bodies. See below for a detailed discussion.

Examples of large rigid bodies are a colloidal particle, or portions of a biomolecule such as a protein.

Example of small rigid bodies are patchy nanoparticles, such as those modeled in this paper by Sharon Glotzer’s group, clumps of granular particles, lipid molecules consisting of one or more point dipoles connected to other spheroids or ellipsoids, irregular particles built from line segments (2d) or triangles (3d), and coarse-grain models of nano or colloidal particles consisting of a small number of constituent particles. Note that the fix shake command can also be used to rigidify small molecules of 2, 3, or 4 atoms, e.g. water molecules. That fix treats the constituent atoms as point masses.

These fixes also update the positions and velocities of the atoms in each rigid body via time integration, in the NVE, NVT, NPT, or NPH ensemble, as described below.

There are two main variants of this fix, fix rigid and fix rigid/small. The NVE/NVT/NPT/NHT versions belong to one of the two variants, as their style names indicate.

Note: Not all of the bodystyle options and keyword/value options are available for both the rigid and rigid/small variants. See details below.

The rigid styles are typically the best choice for a system with a small number of large rigid bodies, each of which can extend across the domain of many processors. It operates by creating a single global list of rigid bodies, which all processors contribute to. MPI_Allreduce operations are performed each timestep to sum the contributions from each processor to the force and torque on all the bodies. This operation will not scale well in parallel if large numbers of rigid bodies are simulated.

The rigid/small styles are typically best for a system with a large number of small rigid bodies. Each body is assigned to the atom closest to the geometrical center of the body. The fix operates using local lists of rigid bodies owned by each processor and information is exchanged and summed via local communication between neighboring processors when ghost atom info is accumulated.

Note: To use the rigid/small styles the ghost atom cutoff must be large enough to span the distance between the atom that owns the body and every other atom in the body. This distance value is printed out when the rigid bodies are defined. If the pair_style cutoff plus neighbor skin does not span this distance, then you should use the comm_modify cutoff command with a setting epsilon larger than the distance.

Which of the two variants is faster for a particular problem is hard to predict. The best way to decide is to perform a short test run. Both variants should give identical numerical answers for short runs. Long runs should give statistically similar results, but round-off differences may accumulate to produce divergent trajectories.

Note: You should not update the atoms in rigid bodies via other time-integration fixes (e.g. fix nve, fix nvt, fix npt, fix move), or you will have conflicting updates to positions and velocities resulting in unphysical behavior in most cases. When performing a hybrid simulation with some atoms in rigid bodies, and some not, a separate time integration fix like fix nve or fix nvt should be used for the non-rigid particles.
Note: These fixes are overkill if you simply want to hold a collection of atoms stationary or have them move with a constant velocity. A simpler way to hold atoms stationary is to not include those atoms in your time integration fix. E.g. use “fix 1 mobile nve” instead of “fix 1 all nve”, where “mobile” is the group of atoms that you want to move. You can move atoms with a constant velocity by assigning them an initial velocity (via the velocity command), setting the force on them to 0.0 (via the fix setforce command), and integrating them as usual (e.g. via the fix nve command).

Warning: The aggregate properties of each rigid body are calculated at the start of a simulation run and are maintained in internal data structures. The properties include the position and velocity of the center-of-mass of the body, its moments of inertia, and its angular momentum. This is done using the properties of the constituent atoms of the body at that point in time (or see the infile keyword option). Thereafter, changing these properties of individual atoms in the body will have no effect on a rigid body’s dynamics, unless they effect any computation of per-atom forces or torques. If the keyword reinit is set to yes (the default), the rigid body data structures will be recreated at the beginning of each run command; if the keyword reinit is set to no, the rigid body data structures will be built only at the very first run command and maintained for as long as the rigid fix is defined. For example, you might think you could displace the atoms in a body or add a large velocity to each atom in a body to make it move in a desired direction before a second run is performed, using the set or displace_atoms or velocity commands. But these commands will not affect the internal attributes of the body unless reinit is set to yes. With reinit set to no (or using the infile option, which implies reinit no) the position and velocity of individual atoms in the body will be reset when time integration starts again.

Each rigid body must have two or more atoms. An atom can belong to at most one rigid body. Which atoms are in which bodies can be defined via several options.

Note: With the rigid/small styles, which require that bodystyle be specified as molecule or custom, you can define a system that has no rigid bodies initially. This is useful when you are using the mol keyword in conjunction with another fix that is adding rigid bodies on-the-fly as molecules, such as fix deposit or fix pour.

For bodystyle single the entire fix group of atoms is treated as one rigid body. This option is only allowed for the rigid styles.

For bodystyle molecule, atoms are grouped into rigid bodies by their respective molecule IDs: each set of atoms in the fix group with the same molecule ID is treated as a different rigid body. This option is allowed for both the rigid and rigid/small styles. Note that atoms with a molecule ID = 0 will be treated as a single rigid body. For a system with atomic solvent (typically this is atoms with molecule ID = 0) surrounding rigid bodies, this may not be what you want. Thus you should be careful to use a fix group that only includes atoms you want to be part of rigid bodies.

Bodystyle custom is similar to bodystyle molecule except that it is more flexible in using other per-atom properties to define the sets of atoms that form rigid bodies. A custom per-atom integer vector defined by the fix property/atom command can be used. Or an atom-style or atomfile-style variable can be used; the floating-point value produced by the variable is rounded to an integer. As with bodystyle molecule, each set of atoms in the fix groups with the same integer value is treated as a different rigid body. Since fix property/atom custom vectors and atom-style variables produce values for all atoms, you should be careful to use a fix group that only includes atoms you want to be part of rigid bodies.

Note: To compute the initial center-of-mass position and other properties of each rigid body, the image flags for each atom in the body are used to “unwrap” the atom coordinates. Thus you must insure that these image flags are consistent so that the unwrapping creates a valid rigid body (one where the atoms are close together), particularly if the atoms in a single rigid body straddle a periodic boundary. This means the input data file or restart file must define the image
flags for each atom consistently or that you have used the set command to specify them correctly. If a dimension is non-periodic then the image flag of each atom must be 0 in that dimension, else an error is generated.

The force and torque keywords discussed next are only allowed for the rigid styles.

By default, each rigid body is acted on by other atoms which induce an external force and torque on its center of mass, causing it to translate and rotate. Components of the external center-of-mass force and torque can be turned off by the force and torque keywords. This may be useful if you wish a body to rotate but not translate, or vice versa, or if you wish it to rotate or translate continuously unaffected by interactions with other particles. Note that if you expect a rigid body not to move or rotate by using these keywords, you must insure its initial center-of-mass translational or angular velocity is 0.0. Otherwise the initial translational or angular momentum the body has will persist.

An xflag, yflag, or zflag set to off means turn off the component of force of torque in that dimension. A setting of on means turn on the component, which is the default. Which rigid body(s) the settings apply to is determined by the first argument of the force and torque keywords. It can be an integer M from 1 to Nbody, where Nbody is the number of rigid bodies defined. A wild-card asterisk can be used in place of, or in conjunction with, the M argument to set the flags for multiple rigid bodies. This takes the form “*” or “*n” or “n*” or “m*n”. If N = the number of rigid bodies, then an asterisk with no numeric values means all bodies from 1 to N. A leading asterisk means all bodies from 1 to n (inclusive). A trailing asterisk means all bodies from n to N (inclusive). A middle asterisk means all types from m to n (inclusive). Note that you can use the force or torque keywords as many times as you like. If a particular rigid body has its component flags set multiple times, the settings from the final keyword are used.

Note: For computational efficiency, you may wish to turn off pairwise and bond interactions within each rigid body, as they no longer contribute to the motion. The neigh_modify exclude and delete_bonds commands are used to do this. If the rigid bodies have strongly overlapping atoms, you may need to turn off these interactions to avoid numerical problems due to large equal/opposite intra-body forces swamping the contribution of small inter-body forces.

For computational efficiency, you should typically define one fix rigid or fix rigid/small command which includes all the desired rigid bodies. LAMMPS will allow multiple rigid fixes to be defined, but it is more expensive.

The constituent particles within a rigid body can be point particles (the default in LAMMPS) or finite-size particles, such as spheres or ellipsoids or line segments or triangles. See the atom_style sphere and ellipsoid and line and tri commands for more details on these kinds of particles. Finite-size particles contribute differently to the moment of inertia of a rigid body than do point particles. Finite-size particles can also experience torque (e.g. due to frictional granular interactions) and have an orientation. These contributions are accounted for by these fixes.

Forces between particles within a body do not contribute to the external force or torque on the body. Thus for computational efficiency, you may wish to turn off pairwise and bond interactions between particles within each rigid body. The neigh_modify exclude and delete_bonds commands are used to do this. For finite-size particles this also means the particles can be highly overlapped when creating the rigid body.

The rigid, rigid/nve, rigid/small, and rigid/small/nve styles perform constant NVE time integration. They are referred to below as the 4 NVE rigid styles. The only difference is that the rigid and rigid/small styles use an integration technique based on Richardson iterations. The rigid/nve and rigid/small/nve styles uses the methods described in the paper by Miller, which are thought to provide better energy conservation than an iterative approach.

The rigid/nvt and rigid/nvt/small styles performs constant NVT integration using a Nose/Hoover thermostat with chains as described originally in (Hoover) and (Martyna), which thermostats both the translational and rotational degrees of freedom of the rigid bodies. They are referred to below as the 2 NVT rigid styles. The rigid-body algorithm used by rigid/nvt is described in the paper by Kamberaj.
The rigid/npt, rigid/nph, rigid/npt/small, and rigid/nph/small styles perform constant NPT or NPH integration using a Nose/Hoover barostat with chains. They are referred to below as the 4 NPT and NPH rigid styles. For the NPT case, the same Nose/Hoover thermostat is also used as with rigid/nvt and rigid/nvt/small.

The barostat parameters are specified using one or more of the iso, aniso, x, y, z and couple keywords. These keywords give you the ability to specify 3 diagonal components of the external stress tensor, and to couple these components together so that the dimensions they represent are varied together during a constant-pressure simulation. The effects of these keywords are similar to those defined in fix npt/nph

Note: Currently the rigid/npt, rigid/nph, rigid/npt/small, and rigid/nph/small styles do not support triclinic (non-orthogonal) boxes.

The target pressures for each of the 6 components of the stress tensor can be specified independently via the x, y, z keywords, which correspond to the 3 simulation box dimensions. For each component, the external pressure or tensor component at each timestep is a ramped value during the run from Pstart to Pstop. If a target pressure is specified for a component, then the corresponding box dimension will change during a simulation. For example, if the y keyword is used, the y-box length will change. A box dimension will not change if that component is not specified, although you have the option to change that dimension via the fix deform command.

For all barostat keywords, the Pdamp parameter operates like the Tdamp parameter, determining the time scale on which pressure is relaxed. For example, a value of 10.0 means to relax the pressure in a timespan of (roughly) 10 time units (e.g. τ or fs or ps - see the units command).

Regardless of what atoms are in the fix group (the only atoms which are time integrated), a global pressure or stress tensor is computed for all atoms. Similarly, when the size of the simulation box is changed, all atoms are re-scaled to new positions, unless the keyword dilate is specified with a dilate-group-ID for a group that represents a subset of the atoms. This can be useful, for example, to leave the coordinates of atoms in a solid substrate unchanged and controlling the pressure of a surrounding fluid. Another example is a system consisting of rigid bodies and point particles where the barostat is only coupled with the rigid bodies. This option should be used with care, since it can be unphysical to dilate some atoms and not others, because it can introduce large, instantaneous displacements between a pair of atoms (one dilated, one not) that are far from the dilation origin.

The couple keyword allows two or three of the diagonal components of the pressure tensor to be “coupled” together. The value specified with the keyword determines which are coupled. For example, xz means the Pxx and Pzz components of the stress tensor are coupled. Xyz means all 3 diagonal components are coupled. Coupling means two things: the instantaneous stress will be computed as an average of the corresponding diagonal components, and the coupled box dimensions will be changed together in lockstep, meaning coupled dimensions will be dilated or contracted by the same percentage every timestep. The Pstart, Pstop, Pdamp parameters for any coupled dimensions must be identical. Couple xyz can be used for a 2d simulation; the z dimension is simply ignored.

The iso and aniso keywords are simply shortcuts that are equivalent to specifying several other keywords together.

The keyword iso means couple all 3 diagonal components together when pressure is computed (hydrostatic pressure), and dilate/contract the dimensions together. Using “iso Pstart Pstop Pdamp” is the same as specifying these 4 keywords:

<table>
<thead>
<tr>
<th>x Pstart Pstop Pdamp</th>
</tr>
</thead>
<tbody>
<tr>
<td>y Pstart Pstop Pdamp</td>
</tr>
<tr>
<td>z Pstart Pstop Pdamp</td>
</tr>
<tr>
<td>couple xyz</td>
</tr>
</tbody>
</table>

The keyword aniso means x, y, and z dimensions are controlled independently using the Pxx, Pyy, and Pzz components of the stress tensor as the driving forces, and the specified scalar external pressure. Using “aniso Pstart Pstop Pdamp” is the same as specifying these 4 keywords:

<table>
<thead>
<tr>
<th>x Pstart Pstop Pdamp</th>
</tr>
</thead>
<tbody>
<tr>
<td>y Pstart Pstop Pdamp</td>
</tr>
</tbody>
</table>

(continues on next page)
The keyword/value option pairs are used in the following ways.

The `reinit` keyword determines, whether the rigid body properties are re-initialized between run commands. With the option `yes` (the default) this is done, with the option `no` this is not done. Turning off the re-initialization can be helpful to protect rigid bodies against unphysical manipulations between runs or when properties cannot be easily re-computed (e.g. when read from a file). When using the `infile` keyword, the `reinit` option is automatically set to `no`.

The `langevin` and `temp` and `tparam` keywords perform thermostatting of the rigid bodies, altering both their translational and rotational degrees of freedom. What is meant by “temperature” of a collection of rigid bodies and how it can be monitored via the fix output is discussed below.

The `langevin` keyword applies a Langevin thermostat to the constant NVE time integration performed by any of the 4 NVE rigid styles: `rigid`, `rigid/nve`, `rigid/small`, `rigid/small/nve`. It cannot be used with the 2 NVT rigid styles: `rigid/nvt`, `rigid/small/nvt`. The desired temperature at each timestep is a ramped value during the run from `Tstart` to `Tstop`. The `Tdamp` parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 100.0 means to relax the temperature in a timespan of (roughly) 100 time units (τ or fs or ps - see the `units` command). The random # seed must be a positive integer.

The way that Langevin thermostatting operates is explained on the `fix langevin` doc page. If you wish to simply viscously damp the rotational motion without thermostatting, you can set `Tstart` and `Tstop` to 0.0, which means only the viscous drag term in the Langevin thermostat will be applied. See the discussion on the `fix viscous` page for details.

**Note:** When the `langevin` keyword is used with fix rigid versus fix rigid/small, different dynamics will result for parallel runs. This is because of the way random numbers are used in the two cases. The dynamics for the two cases should be statistically similar, but will not be identical, even for a single timestep.

The `temp` and `tparam` keywords apply a Nose/Hoover thermostat to the constant NVT time integration performed by the 2 NVT rigid styles. They cannot be used with the 4 NVE rigid styles. The desired temperature at each timestep is a ramped value during the run from `Tstart` to `Tstop`. The `Tdamp` parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 100.0 means to relax the temperature in a timespan of (roughly) 100 time units (τ or fs or ps - see the `units` command).

Nose/Hoover chains are used in conjunction with this thermostat. The `tparam` keyword can optionally be used to change the chain settings used. `Tchain` is the number of thermostats in the Nose Hoover chain. This value, along with `Tdamp` can be varied to dampen undesirable oscillations in temperature that can occur in a simulation. As a rule of thumb, increasing the chain length should lead to smaller oscillations. The keyword `pchain` specifies the number of thermostats in the chain thermostatting the barostat degrees of freedom.

**Note:** There are alternate ways to thermostat a system of rigid bodies. You can use `fix langevin` to treat the individual particles in the rigid bodies as effectively immersed in an implicit solvent, e.g. a Brownian dynamics model. For hybrid systems with both rigid bodies and solvent particles, you can thermostat only the solvent particles that surround one or more rigid bodies by appropriate choice of groups in the compute and fix commands for temperature and thermostatting. The solvent interactions with the rigid bodies should then effectively thermostat the rigid body temperature as well without use of the Langevin or Nose/Hoover options associated with the fix rigid commands.

The `mol` keyword can only be used with the `rigid/small` styles. It must be used when other commands, such as `fix deposit` or `fix pour`, add rigid bodies on-the-fly during a simulation. You specify a `template-ID` previously defined using the
molecule command, which reads a file that defines the molecule. You must use the same template-ID that the other fix which is adding rigid bodies uses. The coordinates, atom types, atom diameters, center-of-mass, and moments of inertia can be specified in the molecule file. See the molecule command for details. The only settings required to be in this file are the coordinates and types of atoms in the molecule, in which case the molecule command calculates the other quantities itself.

Note that these other fixes create new rigid bodies, in addition to those defined initially by this fix via the bodystyle setting.

Also note that when using the mol keyword, extra restart information about all rigid bodies is written out whenever a restart file is written out. See the NOTE in the next section for details.
