The infile keyword allows a file of rigid body attributes to be read in from a file, rather than having LAMMPS compute them. There are 5 such attributes: the total mass of the rigid body, its center-of-mass position, its 6 moments of inertia, its center-of-mass velocity, and the 3 image flags of the center-of-mass position. For rigid bodies consisting of point particles or non-overlapping finite-size particles, LAMMPS can compute these values accurately. However, for rigid bodies consisting of finite-size particles which overlap each other, LAMMPS will ignore the overlaps when computing these 4 attributes. The amount of error this induces depends on the amount of overlap. To avoid this issue, the values can be pre-computed (e.g. using Monte Carlo integration).

The format of the file is as follows. Note that the file does not have to list attributes for every rigid body integrated by fix rigid. Only bodies which the file specifies will have their computed attributes overridden. The file can contain initial blank lines or comment lines starting with “#” which are ignored. The first non-blank, non-comment line should list N = the number of lines to follow. The N successive lines contain the following information:

```
ID1 masstotal xcm ycm zcm ixx iyy izz ixy ixz iyz vxcm vycm vzcm lx ly lz ixcm iycm izcm
ID2 masstotal xcm ycm zcm ixx iyy izz ixy ixz iyz vxcm vycm vzcm lx ly lz ixcm iycm izcm
... IDN masstotal xcm ycm zcm ixx iyy izz ixy ixz iyz vxcm vycm vzcm lx ly lz ixcm iycm izcm
```

The rigid body IDs are all positive integers. For the single bodystyle, only an ID of 1 can be used. For the group bodystyle, IDs from 1 to Ng can be used where Ng is the number of specified groups. For the molecule bodystyle, use the molecule ID for the atoms in a specific rigid body as the rigid body ID.

The masstotal and center-of-mass coordinates (xcm,ycm,zcm) are self-explanatory. The center-of-mass should be consistent with what is calculated for the position of the rigid body with all its atoms unwrapped by their respective image flags. If this produces a center-of-mass that is outside the simulation box, LAMMPS wraps it back into the box.

The 6 moments of inertia (ixx,iyy,izz,ixy,ixz,iyz) should be the values consistent with the current orientation of the rigid body around its center of mass. The values are with respect to the simulation box XYZ axes, not with respect to the principal axes of the rigid body itself. LAMMPS performs the latter calculation internally.

The (vxcm,vycm,vzcm) values are the velocity of the center of mass. The (lx,ly,lz) values are the angular momentum of the body. The (vxcm,vycm,vzcm) and (lx,ly,lz) values can simply be set to 0 if you wish the body to have no initial motion.

The (ixcm,iycm,izcm) values are the image flags of the center of mass of the body. For periodic dimensions, they specify which image of the simulation box the body is considered to be in. An image of 0 means it is inside the box as defined. A value of 2 means add 2 box lengths to get the true value. A value of -1 means subtract 1 box length to get the true value. LAMMPS updates these flags as the rigid bodies cross periodic boundaries during the simulation.

**Note:** If you use the infile or mol keywords and write restart files during a simulation, then each time a restart file is written, the fix also write an auxiliary restart file with the name rfile.rigid, where “rfile” is the name of the restart file, e.g. tmp.restart.10000 and tmp.restart.10000.rigid. This auxiliary file is in the same format described above. Thus it can be used in a new input script that restarts the run and re-speifies a rigid fix using an infile keyword and the
appropriate filename. Note that the auxiliary file will contain one line for every rigid body, even if the original file only listed a subset of the rigid bodies.

If you use a temperature compute with a group that includes particles in rigid bodies, the degrees-of-freedom removed by each rigid body are accounted for in the temperature (and pressure) computation, but only if the temperature group includes all the particles in a particular rigid body.

A 3d rigid body has 6 degrees of freedom (3 translational, 3 rotational), except for a collection of point particles lying on a straight line, which has only 5, e.g. a dimer. A 2d rigid body has 3 degrees of freedom (2 translational, 1 rotational).

**Note:** You may wish to explicitly subtract additional degrees-of-freedom if you use the force and torque keywords to eliminate certain motions of one or more rigid bodies. LAMMPS does not do this automatically.

The rigid body contribution to the pressure of the system (virial) is also accounted for by this fix.

If your simulation is a hybrid model with a mixture of rigid bodies and non-rigid particles (e.g. solvent) there are several ways these rigid fixes can be used in tandem with fix nve, fix nvt, fix npt, and fix nph.

If you wish to perform NVE dynamics (no thermostatting or barostatting), use one of 4 NVE rigid styles to integrate the rigid bodies, and fix nve to integrate the non-rigid particles.

If you wish to perform NVT dynamics (thermostatting, but no barostatting), you can use one of the 2 NVT rigid styles for the rigid bodies, and any thermostatting fix for the non-rigid particles (fix nvt, fix langevin, fix temp/berendsen). You can also use one of the 4 NVE rigid styles for the rigid bodies and thermostat them using fix langevin on the group that contains all the particles in the rigid bodies. The net force added by fix langevin to each rigid body effectively thermostats its translational center-of-mass motion. Not sure how well it does at thermostatting its rotational motion.

If you with to perform NPT or NPH dynamics (barostatting), you cannot use both fix npt and the NPT or NPH rigid styles. This is because there can only be one fix which monitors the global pressure and changes the simulation box dimensions. So you have 3 choices:

- Use one of the 4 NPT or NPH styles for the rigid bodies. Use the dilate all option so that it will dilate the positions of the non-rigid particles as well. Use fix nvt (or any other thermostat) for the non-rigid particles.
- Use fix npt for the group of non-rigid particles. Use the dilate all option so that it will dilate the center-of-mass positions of the rigid bodies as well. Use one of the 4 NVE or 2 NVT rigid styles for the rigid bodies.
- Use fix press/berendsen to compute the pressure and change the box dimensions. Use one of the 4 NVE or 2 NVT rigid styles for the rigid bodies. Use fix nvt (or any other thermostat) for the non-rigid particles.

In all case, the rigid bodies and non-rigid particles both contribute to the global pressure and the box is scaled the same by any of the barostatting fixes.

You could even use the second and third options for a non-hybrid simulation consisting of only rigid bodies, assuming you give fix npt an empty group, though it’s an odd thing to do. The barostatting fixes (fix npt and fix press/berendsen) will monitor the pressure and change the box dimensions, but not time integrate any particles. The integration of the rigid bodies will be performed by fix rigid/nvt.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.
These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

17.183.4 Restart, fix_modify, output, run start/stop, minimize info

No information about the 4 NVE rigid styles is written to binary restart files. The exception is if the `infile` or `mol` keyword is used, in which case an auxiliary file is written with rigid body information each time a restart file is written, as explained above for the `infile` keyword. For the 2 NVT rigid styles, the state of the Nose/Hoover thermostat is written to binary restart files. Ditto for the 4 NPT and NPH rigid styles, and the state of the Nose/Hoover barostat. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The `fix_modify temp` and `press` options are supported by the 4 NPT and NPH rigid styles to change the computes used to calculate the instantaneous pressure tensor. Note that the 2 NVT rigid fixes do not use any external compute to compute instantaneous temperature.

The `fix_modify bodyforces` option is supported by all rigid styles to set whether per-body forces and torques are computed early or late in a timestep, i.e. at the post-force stage or at the final-integrate stage or the timestep, respectively.

The cumulative energy change in the system imposed by the 6 NVT, NPT, NPH rigid fixes, via either thermostatting and/or barostatting, is included in the thermodynamic output keywords `ecouple` and `econserve`. See the thermo_style doc page for details.

The 2 NVE rigid fixes compute a global scalar which can be accessed by various output commands. The scalar value calculated by these fixes is “intensive”. The scalar is the current temperature of the collection of rigid bodies. This is averaged over all rigid bodies and their translational and rotational degrees of freedom. The translational energy of a rigid body is $1/2 \ m \ v^2$, where $m$ = total mass of the body and $v$ = the velocity of its center of mass. The rotational energy of a rigid body is $1/2 \ I \ w^2$, where $I$ = the moment of inertia tensor of the body and $w$ = its angular velocity. Degrees of freedom constrained by the `force` and `torque` keywords are removed from this calculation, but only for the rigid and rigid/nve fixes.

The 6 NVT, NPT, NPH rigid fixes compute a global scalar which can be accessed by various output commands. The scalar is the same cumulative energy change due to these fixes described above. The scalar value calculated by this fix is “extensive”.

The `fix_modify virial` option is supported by these fixes to add the contribution due to the added forces on atoms to both the global pressure and per-atom stress of the system via the `compute pressure` and `compute stress/atom` commands. The former can be accessed by thermodynamic output. The default setting for this fix is `fix_modify virial yes`.

All of the rigid styles (not the rigid/small styles) compute a global array of values which can be accessed by various output commands. Similar information about the bodies defined by the rigid/small styles can be accessed via the compute rigid/local command.

The number of rows in the array is equal to the number of rigid bodies. The number of columns is 15. Thus for each rigid body, 15 values are stored: the xyz coords of the center of mass (COM), the xyz components of the COM velocity, the xyz components of the force acting on the COM, the xyz components of the torque acting on the COM, and the xyz image flags of the COM.

The center of mass (COM) for each body is similar to unwrapped coordinates written to a dump file. It will always be inside (or slightly outside) the simulation box. The image flags have the same meaning as image flags for atom positions (see the “dump” command). This means you can calculate the unwrapped COM by applying the image flags to the COM, the same as when unwrapped coordinates are written to a dump file.
The force and torque values in the array are not affected by the \textit{force} and \textit{torque} keywords in the fix rigid command; they reflect values before any changes are made by those keywords.

The ordering of the rigid bodies (by row in the array) is as follows. For the \textit{single} keyword there is just one rigid body. For the \textit{molecule} keyword, the bodies are ordered by ascending molecule ID. For the \textit{group} keyword, the list of group IDs determines the ordering of bodies.

The array values calculated by these fixes are “intensive”, meaning they are independent of the number of atoms in the simulation.

No parameter of these fixes can be used with the \textit{start/stop} keywords of the \textit{run} command. These fixes are not invoked during \textit{energy minimization}.

\subsection*{17.183.5 Restrictions}

These fixes are all part of the RIGID package. It is only enabled if LAMMPS was built with that package. See the \textit{Build package} page for more info.

Assigning a temperature via the \textit{velocity create} command to a system with \textit{rigid bodies} may not have the desired outcome for two reasons. First, the velocity command can be invoked before the rigid-body fix is invoked or initialized and the number of adjusted degrees of freedom (DOFs) is known. Thus it is not possible to compute the target temperature correctly. Second, the assigned velocities may be partially canceled when constraints are first enforced, leading to a different temperature than desired. A workaround for this is to perform a \textit{run 0} command, which insures all DOFs are accounted for properly, and then rescale the temperature to the desired value before performing a simulation. For example:

\begin{verbatim}
velocity all create 300.0 12345
run 0               # temperature may not be 300K
velocity all scale 300.0       # now it should be
\end{verbatim}

\subsection*{17.183.6 Related commands}

\textit{delete_bonds, neigh_modify exclude, fix shake}

\subsection*{17.183.7 Default}

The option defaults are \textit{force* on on on and torque* on on on}, meaning all rigid bodies are acted on by center-of-mass force and torque. Also \textit{Tchain = Pchain = 10, Titer = 1, Torder = 3, reinit = yes}.  

17.184 fix rigid/meso command

17.184.1 Syntax

| fix ID group-ID rigid/meso bodystyle args keyword values ... |

- ID, group-ID are documented in fix command
- rigid/meso = style name of this fix command
- bodystyle = single or molecule or group
  - single args = none
  - molecule args = none
  - custom args = i_propname or v_varname
    - i_propname = an integer property defined via fix property/atom
    - v_varname = an atom-style or atomfile-style variable
  - group args = N groupID1 groupID2 ...
    - N = # of groups
    - groupID1, groupID2, ... = list of N group IDs
- zero or more keyword/value pairs may be appended
- keyword = reinit or force or torque or infile
  - reinit = yes or no
  - force values = M xflag yflag zflag
    - M = which rigid body from 1-Nbody (see asterisk form below)
    - xflag,yflag,zflag = off/on if component of center-of-mass force is active
  - torque values = M xflag yflag zflag
    - M = which rigid body from 1-Nbody (see asterisk form below)
    - xflag,yflag,zflag = off/on if component of center-of-mass torque is active
  - infile filename
    - filename = file with per-body values of mass, center-of-mass, moments of inertia

17.184.2 Examples

| fix 1 ellipsoid rigid/meso single |
| fix 1 rods rigid/meso molecule |
| fix 1 spheres rigid/meso single force 1 off on |
| fix 1 particles rigid/meso molecule force 1*5 off off force 6*10 off off |
| fix 2 spheres rigid/meso group 3 sphere1 sphere2 sphere3 torque * off off off |

17.184.3 Description

Treat one or more sets of mesoscopic SPH/SDPD particles as independent rigid bodies. This means that each timestep the total force and torque on each rigid body is computed as the sum of the forces and torques on its constituent particles. The coordinates and velocities of the particles in each body are then updated so that the body moves and rotates as a single entity using the methods described in the paper by (Miller). Density and internal energy of the particles will also be updated. This is implemented by creating internal data structures for each rigid body and performing time integration on these data structures. Positions and velocities of the constituent particles are regenerated from the rigid body data structures in every time step. This restricts which operations and fixes can be applied to rigid bodies. See below for a detailed discussion.
The operation of this fix is exactly like that described by the `fix rigid/nve` command, except that particles’ density, internal energy and extrapolated velocity are also updated.

**Note:** You should not update the particles in rigid bodies via other time-integration fixes (e.g. `fix sph`, `fix sph/stationary`), or you will have conflicting updates to positions and velocities resulting in unphysical behavior in most cases. When performing a hybrid simulation with some atoms in rigid bodies, and some not, a separate time integration fix like `fix sph` should be used for the non-rigid particles.

**Note:** These fixes are overkill if you simply want to hold a collection of particles stationary or have them move with a constant velocity. To hold particles stationary use `fix sph/stationary` instead. If you would like to move particles with a constant velocity use `fix meso/move`.

**Warning:** The aggregate properties of each rigid body are calculated at the start of a simulation run and are maintained in internal data structures. The properties include the position and velocity of the center-of-mass of the body, its moments of inertia, and its angular momentum. This is done using the properties of the constituent particles of the body at that point in time (or see the `infile` keyword option). Thereafter, changing these properties of individual particles in the body will have no effect on a rigid body’s dynamics, unless they effect any computation of per-particle forces or torques. If the keyword `reinit` is set to `yes` (the default), the rigid body data structures will be recreated at the beginning of each `run` command; if the keyword `reinit` is set to `no`, the rigid body data structures will be built only at the very first `run` command and maintained for as long as the rigid fix is defined. For example, you might think you could displace the particles in a body or add a large velocity to each particle in a body to make it move in a desired direction before a second run is performed, using the `set` or `displace_atoms` or `velocity` commands. But these commands will not affect the internal attributes of the body unless `reinit` is set to `yes`. With `reinit` set to `no` (or using the `infile` option, which implies `reinit` no) the position and velocity of individual particles in the body will be reset when time integration starts again.

Each rigid body must have two or more particles. A particle can belong to at most one rigid body. Which particles are in which bodies can be defined via several options.

For bodystyle `single` the entire fix group of particles is treated as one rigid body.

For bodystyle `molecule`, particles are grouped into rigid bodies by their respective molecule IDs: each set of particles in the fix group with the same molecule ID is treated as a different rigid body. Note that particles with a molecule ID = 0 will be treated as a single rigid body. For a system with solvent (typically this is particles with molecule ID = 0) surrounding rigid bodies, this may not be what you want. Thus you should be careful to use a fix group that only includes particles you want to be part of rigid bodies.

Bodystyle `custom` is similar to bodystyle `molecule` except that it is more flexible in using other per-atom properties to define the sets of particles that form rigid bodies. An integer vector defined by the `fix property/atom` command can be used. Or an `atom-style` or `atomfile-style` variable can be used; the floating-point value produced by the variable is rounded to an integer. As with bodystyle `molecule`, each set of particles in the fix groups with the same integer value is treated as a different rigid body. Since fix property/atom vectors and atom-style variables produce values for all particles, you should be careful to use a fix group that only includes particles you want to be part of rigid bodies.

For bodystyle `group`, each of the listed groups is treated as a separate rigid body. Only particles that are also in the fix group are included in each rigid body.

**Note:** To compute the initial center-of-mass position and other properties of each rigid body, the image flags for each particle in the body are used to “unwrap” the particle coordinates. Thus you must insure that these image flags are consistent so that the unwrapping creates a valid rigid body (one where the particles are close together), particularly
if the particles in a single rigid body straddle a periodic boundary. This means the input data file or restart file must define the image flags for each particle consistently or that you have used the set command to specify them correctly. If a dimension is non-periodic then the image flag of each particle must be 0 in that dimension, else an error is generated.

By default, each rigid body is acted on by other particles which induce an external force and torque on its center of mass, causing it to translate and rotate. Components of the external center-of-mass force and torque can be turned off by the force and torque keywords. This may be useful if you wish a body to rotate but not translate, or vice versa, or if you wish it to rotate or translate continuously unaffected by interactions with other particles. Note that if you expect a rigid body not to move or rotate by using these keywords, you must insure its initial center-of-mass translational or angular velocity is 0.0. Otherwise the initial translational or angular momentum, the body has, will persist.

An xflag, yflag, or zflag set to off means turn off the component of force or torque in that dimension. A setting of on means turn on the component, which is the default. Which rigid body(s) the settings apply to is determined by the first argument of the force and torque keywords. It can be an integer M from 1 to Nbody, where Nbody is the number of rigid bodies defined. A wild-card asterisk can be used in place of, or in conjunction with, the M argument to set the flags for multiple rigid bodies. This takes the form “*” or “*n” or “n*” or “m*n”. If N = the number of rigid bodies, then an asterisk with no numeric values means all bodies from 1 to N. A leading asterisk means all bodies from 1 to n (inclusive). A trailing asterisk means all bodies from n to N (inclusive). A middle asterisk means all bodies from m to n (inclusive). Note that you can use the force or torque keywords as many times as you like. If a particular rigid body has its component flags set multiple times, the settings from the final keyword are used.

For computational efficiency, you should typically define one fix rigid/meso command which includes all the desired rigid bodies. LAMMPS will allow multiple rigid/meso fixes to be defined, but it is more expensive.

The keyword/value option pairs are used in the following ways.

The reinit keyword determines, whether the rigid body properties are re-initialized between run commands. With the option yes (the default) this is done, with the option no this is not done. Turning off the re-initialization can be helpful to protect rigid bodies against unphysical manipulations between runs or when properties cannot be easily re-computed (e.g. when read from a file). When using the infile keyword, the reinit option is automatically set to no.

The infile keyword allows a file of rigid body attributes to be read in from a file, rather than having LAMMPS compute them. There are 5 such attributes: the total mass of the rigid body, its center-of-mass position, its 6 moments of inertia, its center-of-mass velocity, and the 3 image flags of the center-of-mass position. For rigid bodies consisting of point particles or non-overlapping finite-size particles, LAMMPS can compute these values accurately. However, for rigid bodies consisting of finite-size particles which overlap each other, LAMMPS will ignore the overlaps when computing these 4 attributes. The amount of error this induces depends on the amount of overlap. To avoid this issue, the values can be pre-computed (e.g. using Monte Carlo integration).

The format of the file is as follows. Note that the file does not have to list attributes for every rigid body integrated by fix rigid. Only bodies which the file specifies will have their computed attributes overridden. The file can contain initial blank lines or comment lines starting with “#” which are ignored. The first non-blank, non-comment line should list N = the number of lines to follow. The N successive lines contain the following information:

```
ID1 masstotal xcm ycm zcm ixx iyy izz ixy iyz ixz vxcm vycm vzcm lx ly lz ixcm iycm izcm
ID2 masstotal xcm ycm zcm ixx iyy izz ixy iyz ixz vxcm vycm vzcm lx ly lz ixcm iycm izcm
... IDN masstotal xcm ycm zcm ixx iyy izz ixy iyz ixz vxcm vycm vzcm lx ly lz ixcm iycm izcm
```

The rigid body IDs are all positive integers. For the single bodystyle, only an ID of 1 can be used. For the group bodystyle, IDs from 1 to Ng can be used where Ng is the number of specified groups. For the molecule bodystyle, use the molecule ID for the atoms in a specific rigid body as the rigid body ID.
The mass total and center-of-mass coordinates \((x_{cm}, y_{cm}, z_{cm})\) are self-explanatory. The center-of-mass should be consistent with what is calculated for the position of the rigid body with all its atoms unwrapped by their respective image flags. If this produces a center-of-mass that is outside the simulation box, LAMMPS wraps it back into the box.

The 6 moments of inertia \((i_{xx}, i_{yy}, i_{zz}, i_{xy}, i_{xz}, i_{yz})\) should be the values consistent with the current orientation of the rigid body around its center of mass. The values are with respect to the simulation box XYZ axes, not with respect to the principal axes of the rigid body itself. LAMMPS performs the latter calculation internally.

The \((v_{xcm}, v_{ycm}, v_{zcm})\) values are the velocity of the center of mass. The \((l_x, l_y, l_z)\) values are the angular momentum of the body. The \((v_{xcm}, v_{ycm}, v_{zcm})\) and \((l_x, l_y, l_z)\) values can simply be set to 0 if you wish the body to have no initial motion.

The \((i_{xcm}, i_{ycm}, i_{zcm})\) values are the image flags of the center of mass of the body. For periodic dimensions, they specify which image of the simulation box the body is considered to be in. An image of 0 means it is inside the box as defined. A value of 2 means add 2 box lengths to get the true value. A value of -1 means subtract 1 box length to get the true value. LAMMPS updates these flags as the rigid bodies cross periodic boundaries during the simulation.

**Note:** If you use the `infile` keyword and write restart files during a simulation, then each time a restart file is written, the fix also write an auxiliary restart file with the name rfile.rigid, where “rfile” is the name of the restart file, e.g. tmp.restart.10000 and tmp.restart.10000.rigid. This auxiliary file is in the same format described above. Thus it can be used in a new input script that restarts the run and re-specifies a rigid fix using an `infile` keyword and the appropriate filename. Note that the auxiliary file will contain one line for every rigid body, even if the original file only listed a subset of the rigid bodies.

**17.184.4 Restart, fix_modify, output, run start/stop, minimize info**

No information is written to binary restart files. If the `infile` keyword is used, an auxiliary file is written out with rigid body information each time a restart file is written, as explained above for the `infile` keyword.

None of the `fix_modify` options are relevant to this fix.

This fix computes a global array of values which can be accessed by various output commands.

The number of rows in the array is equal to the number of rigid bodies. The number of columns is 28. Thus for each rigid body, 28 values are stored: the xyz coords of the center of mass (COM), the xyz components of the COM velocity, the xyz components of the force acting on the COM, the components of the 4-vector quaternion representing the orientation of the rigid body, the xyz components of the angular velocity of the body around its COM, the xyz components of the torque acting on the COM, the 3 principal components of the moment of inertia, the xyz components of the angular momentum of the body around its COM, and the xyz image flags of the COM.

The center of mass (COM) for each body is similar to unwrapped coordinates written to a dump file. It will always be inside (or slightly outside) the simulation box. The image flags have the same meaning as image flags for particle positions (see the “dump” command). This means you can calculate the unwrapped COM by applying the image flags to the COM, the same as when unwrapped coordinates are written to a dump file.

The force and torque values in the array are not affected by the `force` and `torque` keywords in the fix rigid command; they reflect values before any changes are made by those keywords.

The ordering of the rigid bodies (by row in the array) is as follows. For the `single` keyword there is just one rigid body. For the `molecule` keyword, the bodies are ordered by ascending molecule ID. For the `group` keyword, the list of group IDs determines the ordering of bodies.

The array values calculated by this fix are “intensive”, meaning they are independent of the number of particles in the simulation.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command.
This fix is not invoked during energy minimization.

### 17.184.5 Restrictions

This fix is part of the DPD-SMOOTH package and also depends on the RIGID package. It is only enabled if LAMMPS was built with both packages. See the Build package page for more info. This fix requires that atoms store density and internal energy as defined by the atom_style sph command. All particles in the group must be mesoscopic SPH/SDPD particles.

### 17.184.6 Related commands

fix meso/move, fix rigid, neigh_modify exclude

### 17.184.7 Default

The option defaults are force * on on on and torque * on on on, meaning all rigid bodies are acted on by center-of-mass force and torque. Also reinit = yes.

### 17.185 fix rx command

Accelerator Variants: rx/kk

### 17.185.1 Syntax

```
fix ID group-ID rx file localTemp matrix solver minSteps ...
```

- ID, group-ID are documented in fix command
- rx = style name of this fix command
- file = filename containing the reaction kinetic equations and Arrhenius parameters
- localTemp = none, lucy = no local temperature averaging or local temperature defined through Lucy weighting function
- matrix = sparse, dense format for the stoichiometric matrix
- solver = lammps_rk4, rkf45 = rk4 is an explicit fourth order Runge-Kutta method; rkf45 is an adaptive fourth-order Runge-Kutta-Fehlberg method
- minSteps = # of steps for rk4 solver or minimum # of steps for rkf45 (rk4 or rkf45)
- maxSteps = maximum number of steps for the rkf45 solver (rkf45 only)
- relTol = relative tolerance for the rkf45 solver (rkf45 only)
- absTol = absolute tolerance for the rkf45 solver (rkf45 only)
- diag = Diagnostics frequency for the rkf45 solver (optional, rkf45 only)
17.185.2 Examples

```
fix 1 all rx kinetics.rx none dense lammps_rk4
fix 1 all rx kinetics.rx none sparse lammps_rk4 1
fix 1 all rx kinetics.rx lucy sparse lammps_rk4 10
fix 1 all rx kinetics.rx none dense rkf45 1 100 1e-6 1e-8
fix 1 all rx kinetics.rx none dense rkf45 1 100 1e-6 1e-8 -1
```

17.185.3 Description

Fix rx solves the reaction kinetic ODEs for a given reaction set that is defined within the file associated with this command.

For a general reaction such that

\[ \nu_A A + \nu_B B \rightarrow \nu_C C \]

the reaction rate equation is defined to be of the form

\[ r = k(T)[A]^{\nu_A}[B]^{\nu_B} \]

In the current implementation, the exponents are defined to be equal to the stoichiometric coefficients. A given reaction set consisting of \( n \) reaction equations will contain a total of \( m \) species. A set of \( m \) ordinary differential equations (ODEs) that describe the change in concentration of a given species as a function of time are then constructed based on the \( n \) reaction rate equations.

The ODE systems are solved over the full DPD timestep \( dt \) using either a fourth order Runge-Kutta \( rk4 \) method with a fixed step-size \( h \), specified by the lammps_rk4 keyword, or a fourth order Runge-Kutta-Fehlberg (rkf45) method with an adaptive step-size for \( h \). The number of ODE steps per DPD timestep for the \( rk4 \) method is optionally specified immediately after the \( rk4 \) keyword. The ODE step-size is set as \( dt/\text{num\_steps} \). Smaller step-sizes tend to yield more accurate results but there is not control on the error. For error control, use the \( rkf45 \) ODE solver.

The \( rkf45 \) method adjusts the step-size so that the local truncation error is held within the specified absolute and relative tolerances. The initial step-size \( h_0 \) can be specified by the user or estimated internally. It is recommended that the user specify \( h_0 \) since this will generally reduced the number of ODE integration steps required. \( h_0 \) is defined as \( dt/\min\_steps \) if \( \min\_steps \geq 1 \). If \( \min\_steps == 0 \), \( h_0 \) is estimated such that an explicit Euler method would likely produce an acceptable solution. This is generally overly conservative for the fourth-order method and users are advised to specify \( h_0 \) as some fraction of the DPD timestep. For small DPD timesteps, only one step may be necessary depending upon the tolerances. Note that more than \( \min\_steps \) ODE steps may be taken depending upon the ODE stiffness but no more than \( \max\_steps \) will be taken. If \( \max\_steps \) is reached, an error warning is printed and the simulation is stopped.

After each ODE step, the solution error \( e \) is tested and weighted using the absTol and relTol values. The error vector is weighted as \( e / (\text{relTol} * |u| + \text{absTol}) \) where \( u \) is the solution vector. If the norm of the error is \( <= 1 \), the solution is accepted, \( h \) is increased by a proportional amount, and the next ODE step is begun. Otherwise, \( h \) is shrunk and the ODE step is repeated.

Run-time diagnostics are available for the \( rkf45 \) ODE solver. The frequency (in timesteps) that diagnostics are reported is controlled by the last (optional) 12th argument. A negative frequency means that diagnostics are reported once at the end of each run. A positive value \( N \) means that the diagnostics are reported once per \( N \) timesteps.

The diagnostics report the average # of integrator steps and RHS function evaluations and run-time per ODE as well as the average/RMS/min/max per process. If the reporting frequency is 1, the RMS/min/max per ODE are also reported. The per ODE statistics can be used to adjust the tolerance and min/max step parameters. The statistics per MPI process can be useful to examine any load imbalance caused by the adaptive ODE solver. (Some DPD particles can take longer to solve than others. This can lead to an imbalance across the MPI processes.)
The filename specifies a file that contains the entire set of reaction kinetic equations and corresponding Arrhenius parameters. The format of this file is described below.

There is no restriction on the total number or reaction equations that are specified. The species names are arbitrary string names that are associated with the species concentrations. Each species in a given reaction must be preceded by its stoichiometric coefficient. The only delimiters that are recognized between the species are either a + or = character. The = character corresponds to an irreversible reaction. After specifying the reaction, the reaction rate constant is determined through the temperature dependent Arrhenius equation:

\[ k = AT^n e^{\frac{-E_a}{k_BT}} \]

where \( A \) is the Arrhenius factor in time units or concentration/time units, \( n \) is the unitless exponent of the temperature dependence, and \( E_a \) is the activation energy in energy units. The temperature dependence can be removed by specifying the exponent as zero.

The internal temperature of the coarse-grained particles can be used in constructing the reaction rate constants at every DPD timestep by specifying the keyword none. Alternatively, the keyword lucy can be specified to compute a local-average particle internal temperature for use in the reaction rate constant expressions. The local-average particle internal temperature is defined as:

\[ \theta_i^{-1} = \sum_{j=1}^{\omega_{Lucy}} \theta_j^{-1} \]

\[ \omega_{Lucy}(r_{ij}) = \left(1 + \frac{3r_{ij}}{r_c}\right)\left(1 - \frac{r_{ij}}{r_c}\right)^3 \]

The self-particle interaction is included in the above equation.

The stoichiometric coefficients for the reaction mechanism are stored in either a sparse or dense matrix format. The dense matrix should only be used for small reaction mechanisms. The sparse matrix should be used when there are many reactions (e.g., more than 5). This allows the number of reactions and species to grow while keeping the computational cost tractable. The matrix format can be specified as using either the sparse or dense keywords. If all stoichiometric coefficients for a reaction are small integers (whole numbers <= 3), a fast exponential function is used. This can save significant computational time so users are encouraged to use integer coefficients where possible.

The format of a tabulated file is as follows (without the parenthesized comments):

```
# Rxn equations and parameters (one or
  more comment or blank lines)
1.0 hcn + 1.0 no2 = 1.0 no + 0.5 n2 + 0.5 h2 + 1.0 co 2.49E+01 0.0 1.34 (rxn_)
  equation, A, n, Ea)
1.0 hcn + 1.0 no = 1.0 co + 1.0 n2 + 0.5 h2 2.16E+00 0.0 1.52
...
1.0 no + 1.0 co = 0.5 n2 + 1.0 co2 1.66E+06 0.0 0.69
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections.

Following a blank line, the next N lines list the N reaction equations. Each species within the reaction equation is specified through its stoichiometric coefficient and a species tag. Reactant species are specified on the left-hand side of the equation and product species are specified on the right-hand side of the equation. After specifying the reactant and product species, the final three arguments of each line represent the Arrhenius parameter \( A \), the temperature exponent \( n \), and the activation energy \( E_a \).
Note that the species tags that are defined in the reaction equations are used by the `fix eos/table/rx` command to define the thermodynamic properties of each species. Furthermore, the number of species molecules (i.e., concentration) can be specified either with the `set` command using the “d_” prefix or by reading directly the concentrations from a data file. For the latter case, the `read_data` command with the fix keyword should be specified, where the fix-ID will be the “fix rx’ID with a <SPECIES>”_ suffix, e.g.

```yaml
fix foo all rx reaction.file ... read_data data.dpd fix foo_SPECIES NULL Species
```

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 17.185.4 Restrictions

This command is part of the DPD-REACT package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This command also requires use of the `atom_style dpd` command.

This command can only be used with a constant energy or constant enthalpy DPD simulation.

### 17.185.5 Related commands

- `fix eos/table/rx`, `fix shardlow`, `pair dpd/fdt/energy`

### 17.185.6 Default

None

### 17.186 fix saed/vtk command

#### 17.186.1 Syntax

```yaml
fix ID group-ID saed/vtk Nevery Nrepeat Nfreak c_ID attribute args ... keyword args ...```

- ID, group-ID are documented in `fix` command
- `saed/vtk` = style name of this fix command
- `Nevery` = use input values every this many timesteps
- `Nrepeat` = # of times to use input values for calculating averages
• Nfreq = calculate averages every this many timesteps
• c_ID = saed compute ID

    keyword = file or ave or start or file or overwrite: 
    ave args = one or running or window M
    one = output a new average value every Nfreq steps
    running = output cumulative average of all previous Nfreq steps
    window M = output average of M most recent Nfreq steps
    start args = Nstart
    Nstart = start averaging on this timestep
    file arg = filename
    filename = name of file to output time averages to

17.186.2 Examples

    compute 1 all saed 0.0251 Al O Kmax 1.70 Zone 0 0 1 dR_Ewald 0.01 c 0.5 0.5 0.5
    compute 2 all saed 0.0251 Ni Kmax 1.70 Zone 0 0 0 c 0.05 0.05 0.05 manual echo

    fix 1 all saed/vtk 1 1 1 c_1 file Al203_001.saed
    fix 2 all saed/vtk 1 1 1 c_2 file Ni_000.saed

17.186.3 Description

Time average computed intensities from compute saed and write output to a file in the third generation vtk image data format for visualization directly in parallelized visualization software packages like ParaView and VisIt. Note that if no time averaging is done, this command can be used as a convenient way to simply output diffraction intensities at a single snapshot.

To produce output in the image data vtk format ghost data is added outside the Kmax range assigned in the compute saed. The ghost data is assigned a value of -1 and can be removed setting a minimum isovolume of 0 within the visualization software. SAED images can be created by visualizing a spherical slice of the data that is centered at R_Ewald*[h k l]/norm([h k l]), where R_Ewald=l/lambda.

The group specified within this command is ignored. However, note that specified values may represent calculations performed by saed computes which store their own “group” definitions.

Fix saed/vtk is designed to work only with compute saed values, e.g.

    compute 3 top saed 0.0251 Al 0
    fix saed/vtk 1 1 1 c_3 file Al203_001.saed

The Nevery, Nrepeat, and Nfreq arguments specify on what timesteps the input values will be used in order to contribute to the average. The final averaged quantities are generated on timesteps that are a multiple of Nfreq. The average is over Nrepeat quantities, computed in the preceding portion of the simulation every Nevery timesteps. Nfreq must be a multiple of Nevery and Nevery must be non-zero even if Nrepeat is 1. Also, the timesteps contributing to the average value cannot overlap, i.e. Nrepeat*Nevery can not exceed Nfreq.

For example, if Nevery=2, Nrepeat=6, and Nfreq=100, then values on timesteps 90,92,94,96,98,100 will be used to compute the final average on timestep 100. Similarly for timesteps 190,192,194,196,198,200 on timestep 200, etc. If Nrepeat=1 and Nfreq = 100, then no time averaging is done; values are simply generated on timesteps 100,200, etc.
The output for fix ave/time/saed is a file written with the third generation vtk image data formatting. The filename assigned by the file keyword is appended with _N.vtk where N is an index (0,1,2...) to account for multiple diffraction intensity outputs.

By default the header contains the following information (with example data):

```
# vtk DataFile Version 3.0 c_SAED
Image data set
ASCII
DATASET STRUCTURED_POINTS
DIMENSIONS 337 219 209
ASPECT_RATIO 0.00507953 0.00785161 0.00821458
ORIGIN -0.853361 -0.855826 -0.854316
POINT_DATA 15424827
SCALARS intensity float
LOOKUP_TABLE default
...data
```

In this example, kspace is sampled across a 337 x 219 x 209 point mesh where the mesh spacing is approximately 0.005, 0.007, and 0.008 inv(length) units in the k1, k2, and k3 directions, respectively. The data is shifted by -0.85, -0.85, -0.85 inv(length) units so that the origin will lie at 0, 0, 0. Here, 15,424,827 kspace points are sampled in total.

Additional optional keywords also affect the operation of this fix.

The ave keyword determines how the values produced every Nfreq steps are averaged with values produced on previous steps that were multiples of Nfreq, before they are accessed by another output command or written to a file.

If the ave setting is one, then the values produced on timesteps that are multiples of Nfreq are independent of each other; they are output as-is without further averaging.

If the ave setting is running, then the values produced on timesteps that are multiples of Nfreq are summed and averaged in a cumulative sense before being output. Each output value is thus the average of the value produced on that timestep with all preceding values. This running average begins when the fix is defined; it can only be restarted by deleting the fix via the unfix command, or by re-defining the fix by re-specifying it.

If the ave setting is window, then the values produced on timesteps that are multiples of Nfreq are summed and averaged within a moving “window” of time, so that the last M values are used to produce the output. E.g. if M = 3 and Nfreq = 1000, then the output on step 10000 will be the average of the individual values on steps 8000,9000,10000. Outputs on early steps will average over less than M values if they are not available.

The start keyword specifies what timestep averaging will begin on. The default is step 0. Often input values can be 0.0 at time 0, so setting start to a larger value can avoid including a 0.0 in a running or windowed average.

The file keyword allows a filename to be specified. Every Nfreq steps, the vector of saed intensity data is written to a new file using the third generation vtk format. The base of each file is assigned by the file keyword and this string is appended with _N.vtk where N is an index (0,1,2...) to account for situations with multiple diffraction intensity outputs.
17.186.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.186.5 Restrictions

The attributes for fix_saed_vtk must match the values assigned in the associated compute_saed command.

17.186.6 Related commands

compute_saed

17.186.7 Default

The option defaults are ave = one, start = 0, no file output.

17.187 fix setforce command

Accelerator Variants: setforce/kk

17.188 fix setforce/spin command

17.188.1 Syntax

```plaintext
fix ID group-ID setforce fx fy fz keyword value ...
```

- ID, group-ID are documented in fix command
- setforce = style name of this fix command
- fx,fy,fz = force component values
- any of fx,fy,fz can be a variable (see below)
- zero or more keyword/value pairs may be appended to args
- keyword = region
  ```plaintext
  region value = region-ID
  region-ID = ID of region atoms must be in to have added force
  ```
17.188.2 Examples

<table>
<thead>
<tr>
<th>fix</th>
<th>freeze indenter setforce 0.0 0.0 0.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>fix</td>
<td>2 edge setforce NULL 0.0 0.0</td>
</tr>
<tr>
<td>fix</td>
<td>1 edge setforce/spin 0.0 0.0 0.0</td>
</tr>
<tr>
<td>fix</td>
<td>2 edge setforce NULL 0.0 v_oscillate</td>
</tr>
</tbody>
</table>

17.188.3 Description

Set each component of force on each atom in the group to the specified values fx, fy, fz. This erases all previously computed forces on the atom, though additional fixes could add new forces. This command can be used to freeze certain atoms in the simulation by zeroing their force, either for running dynamics or performing an energy minimization. For dynamics, this assumes their initial velocity is also zero.

Any of the fx, fy, fz values can be specified as NULL which means do not alter the force component in that dimension.

Any of the 3 quantities defining the force components can be specified as an equal-style or atom-style variable, namely fx, fy, fz. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the force component.

Equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent force field.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus it is easy to specify a spatially-dependent force field with optional time-dependence as well.

If the region keyword is used, the atom must also be in the specified geometric region in order to have force added to it.

Style spin suffix sets the components of the magnetic precession vectors instead of the mechanical forces. This also erases all previously computed magnetic precession vectors on the atom, though additional magnetic fixes could add new forces.

This command can be used to freeze the magnetic moment of certain atoms in the simulation by zeroing their precession vector.

All options defined above remain valid, they just apply to the magnetic precession vectors instead of the forces.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

**Note:** The region keyword is supported by Kokkos, but a Kokkos-enabled region must be used. See the region region command for more information.
17.188.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is setting the forces to the desired values; on all other levels, the force is set to 0.0 for the atoms in the fix group, so that setforce values are not counted multiple times. Default is to to override forces at the outermost level.

This fix computes a global 3-vector of forces, which can be accessed by various output commands. This is the total force on the group of atoms before the forces on individual atoms are changed by the fix. The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command, but you cannot set forces to any value besides zero when performing a minimization. Use the fix addforce command if you want to apply a non-zero force to atoms during a minimization.

17.188.5 Restrictions

The fix setforce/spin only makes sense when LAMMPS was built with the SPIN package.

fix 1 sub rattle 0.0001 20 10 t 5 6 m 1.0 a 31 mol myMol
```

17.190.3 Description

Apply bond and angle constraints to specified bonds and angles in the simulation by either the SHAKE or RATTLE algorithms. This typically enables a longer timestep.

**SHAKE vs RATTLE:**

The SHAKE algorithm was invented for schemes such as standard Verlet time-stepping, where only the coordinates are integrated and the velocities are approximated as finite differences to the trajectories (Ryckaert et al. (1977)). If the velocities are integrated explicitly, as with velocity Verlet which is what LAMMPS uses as an integration method, a second set of constraining forces is required in order to eliminate velocity components along the bonds (Andersen (1983)).

In order to formulate individual constraints for SHAKE and RATTLE, focus on a single molecule whose bonds are constrained. Let Ri and Vi be the position and velocity of atom i at time n, for i=1,...,N, where N is the number of sites of our reference molecule. The distance vector between sites i and j is given by

\[
r_{ij}^{n+1} = r_{ij}^n - r_{ij}^n
\]

The constraints can then be formulated as

\[
r_{ij}^{n+1} \cdot r_{ij}^{n+1} = d_{ij}^2 \quad \text{and} \quad v_{ij}^{n+1} \cdot r_{ij}^{n+1} = 0
\]

The SHAKE algorithm satisfies the first condition, i.e. the sites at time \(n+1\) will have the desired separations \(D_{ij}\) immediately after the coordinates are integrated. If we also enforce the second condition, the velocity components along the bonds will vanish. RATTLE satisfies both conditions. As implemented in LAMMPS, fix rattle uses fix shake for satisfying the coordinate constraints. Therefore the settings and optional keywords are the same for both fixes, and all the information below about SHAKE is also relevant for RATTLE.

**SHAKE:**
Each timestep the specified bonds and angles are reset to their equilibrium lengths and angular values via the SHAKE algorithm \((\text{Ryckaert et al. (1977)})\). This is done by applying an additional constraint force so that the new positions preserve the desired atom separations. The equations for the additional force are solved via an iterative method that typically converges to an accurate solution in a few iterations. The desired tolerance (e.g. \(1.0\cdot10^{-4} = 1\) part in 10000) and maximum # of iterations are specified as arguments. Setting the \(N\) argument will print statistics to the screen and log file about regarding the lengths of bonds and angles that are being constrained. Small delta values mean SHAKE is doing a good job.

In LAMMPS, only small clusters of atoms can be constrained. This is so the constraint calculation for a cluster can be performed by a single processor, to enable good parallel performance. A cluster is defined as a central atom connected to others in the cluster by constrained bonds. LAMMPS allows for the following kinds of clusters to be constrained: one central atom bonded to 1 or 2 or 3 atoms, or one central atom bonded to 2 others and the angle between the 3 atoms also constrained. This means water molecules or \(\text{CH}_2\) or \(\text{CH}_3\) groups may be constrained, but not all the C-C backbone bonds of a long polymer chain.

The \(b\) constraint lists bond types that will be constrained. The \(t\) constraint lists atom types. All bonds connected to an atom of the specified type will be constrained. The \(m\) constraint lists atom masses. All bonds connected to atoms of the specified masses will be constrained (within a fudge factor of MASSDELTA specified in fix_shake.cpp). The \(a\) constraint lists angle types. If both bonds in the angle are constrained then the angle will also be constrained if its type is in the list.

For all constraints, a particular bond is only constrained if both atoms in the bond are in the group specified with the SHAKE fix.

The degrees-of-freedom removed by SHAKE bonds and angles are accounted for in temperature and pressure computations. Similarly, the SHAKE contribution to the pressure of the system (virial) is also accounted for.

**Note:** This command works by using the current forces on atoms to calculate an additional constraint force which when added will leave the atoms in positions that satisfy the SHAKE constraints (e.g. bond length) after the next time integration step. If you define fixes (e.g. \textbf{fix efield}) that add additional force to the atoms after fix shake operates, then this fix will not take them into account and the time integration will typically not satisfy the SHAKE constraints. The solution for this is to make sure that fix shake is defined in your input script after any other fixes which add or change forces (to atoms that fix shake operates on).

The \textbf{mol} keyword should be used when other commands, such as \textbf{fix deposit} or \textbf{fix pour}, add molecules on-the-fly during a simulation, and you wish to constrain the new molecules via SHAKE. You specify a \textit{template-ID} previously defined using the \textbf{molecule} command, which reads a file that defines the molecule. You must use the same \textit{template-ID} that the command adding molecules uses. The coordinates, atom types, special bond restrictions, and SHAKE info can be specified in the molecule file. See the \textbf{molecule} command for details. The only settings required to be in this file (by this command) are the SHAKE info of atoms in the molecule.

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Accelerator packages} page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -\textit{suffix} \textit{command-line switch} when you invoke LAMMPS, or you can use the \textit{suffix} command in your input script.

See the \textit{Accelerator packages} page for more instructions on how to use the accelerated styles effectively.
RATTLE:
The velocity constraints lead to a linear system of equations which can be solved analytically. The implementation of the algorithm in LAMMPS closely follows (Andersen (1983)).

Note: The fix rattle command modifies forces and velocities and thus should be defined after all other integration fixes in your input script. If you define other fixes that modify velocities or forces after fix rattle operates, then fix rattle will not take them into account and the overall time integration will typically not satisfy the RATTLE constraints. You can check whether the constraints work correctly by setting the value of RATTLE_DEBUG in src/fix_rattle.cpp to 1 and recompiling LAMMPS.

17.190.4 Restart, fix_modify, output, run start/stop, minimize info

No information about these fixes is written to binary restart files.

The fix_modify virial option is supported by these fixes to add the contribution due to the added forces on atoms to both the global pressure and per-atom stress of the system via the compute pressure and compute stress/atom commands. The former can be accessed by thermodynamic output. The default setting for this fix is fix_modify virial yes.

No global or per-atom quantities are stored by these fixes for access by various output commands. No parameter of these fixes can be used with the start/stop keywords of the run command. These fixes are not invoked during energy minimization.

17.190.5 Restrictions

These fixes are part of the RIGID package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

For computational efficiency, there can only be one shake or rattle fix defined in a simulation.

If you use a tolerance that is too large or a max-iteration count that is too small, the constraints will not be enforced very strongly, which can lead to poor energy conservation. You can test for this in your system by running a constant NVE simulation with a particular set of SHAKE parameters and monitoring the energy versus time.

SHAKE or RATTLE should not be used to constrain an angle at 180 degrees (e.g. linear CO2 molecule). This causes numeric difficulties. You can use fix rigid or fix rigid/small instead to make a linear molecule rigid.

17.190.6 Related commands

none

17.190.7 Default

none

17.191  fix shardlow command

Accelerator Variants: shardlow/kk

17.191.1 Syntax

```plaintext
fix ID group-ID shardlow
```

- ID, group-ID are documented in `fix` command
- shardlow = style name of this fix command

17.191.2 Examples

```plaintext
fix 1 all shardlow
```

17.191.3 Description

Specifies that the Shardlow splitting algorithm (SSA) is to be used to integrate the DPD equations of motion. The SSA splits the integration into a stochastic and deterministic integration step. The `fix shardlow` performs the stochastic integration step and must be used in conjunction with a deterministic integrator (e.g. `fix nve` or `fix nph`). The stochastic integration of the dissipative and random forces is performed prior to the deterministic integration of the conservative force. Further details regarding the method are provided in (Lisal) and (Larentzos1).

The `fix shardlow` must be used with the `pair_style dpd/fdt` or `pair_style dpd/fdt/energy` command to properly initialize the fluctuation-dissipation theorem parameter(s) sigma (and kappa, if necessary).

Note that numerous variants of DPD can be specified by choosing an appropriate combination of the integrator and `pair_style dpd/fdt` command. DPD under isothermal conditions can be specified by using `fix shardlow`, `fix nve` and `pair_style dpd/fdt`. DPD under isoenergetic conditions can be specified by using `fix shardlow`, `fix nve` and `pair_style dpd/fdt/energy`. DPD under isobaric conditions can be specified by using `fix shardlow`, `fix nph` and `pair_style dpd/fdt`. DPD under isenthalpic conditions can be specified by using `fix shardlow`, `fix nph` and `pair_style dpd/fdt/energy`. Examples of each DPD variant are provided in the examples/PACKAGES/dpd-react directory.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
17.191.4 Restrictions

This command is part of the DPD-REACT package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This fix is currently limited to orthogonal simulation cell geometries.

This fix must be used with an additional fix that specifies time integration, e.g. fix nve or fix nph.

The Shardlow splitting algorithm requires the sizes of the sub-domain lengths to be larger than twice the cutoff+skin.

Generally, the domain decomposition is dependent on the number of processors requested.

fix pull cterm smd cfor 5.0 tether 25.0 25.0 25.0 0.0
```

17.192.3 Description

This fix implements several options of steered MD (SMD) as reviewed in (Izrailev), which allows to induce conformational changes in systems and to compute the potential of mean force (PMF) along the assumed reaction coordinate (Park) based on Jarzynski’s equality (Jarzynski). This fix borrows a lot from fix spring and fix setforce.

You can apply a moving spring force to a group of atoms (tether style) or between two groups of atoms (couple style). The spring can then be used in either constant velocity (cvel) mode or in constant force (cfor) mode to induce transitions in your systems. When running in tether style, you may need some way to fix some other part of the system (e.g. via fix spring/self)

The **tether** style attaches a spring between a point at a distance of R0 away from a fixed point x,y,z and the center of mass of the fix group of atoms. A restoring force of magnitude K (R - R0) Mi / M is applied to each atom in the group where K is the spring constant, Mi is the mass of the atom, and M is the total mass of all atoms in the group. Note that K thus represents the total force on the group of atoms, not a per-atom force.

In cvel mode the distance R is incremented or decremented monotonously according to the pulling (or pushing) velocity. In cfor mode a constant force is added and the actual distance in direction of the spring is recorded.

The **couple** style links two groups of atoms together. The first group is the fix group; the second is specified by group-ID2. The groups are coupled together by a spring that is at equilibrium when the two groups are displaced by a vector in direction x,y,z with respect to each other and at a distance R0 from that displacement. Note that x,y,z only provides a direction and will be internally normalized. But since it represents the absolute displacement of group-ID2 relative to the fix group, (1,1,0) is a different spring than (-1,-1,0). For each vector component, the displacement can be described with the **auto** parameter. In this case the direction is re-computed in every step, which can be useful for steering a local process where the whole object undergoes some other change. When the relative positions and distance between the two groups are not in equilibrium, the same spring force described above is applied to atoms in each of the two groups.

For both the **tether** and **couple** styles, any of the x,y,z values can be specified as NULL which means do not include that dimension in the distance calculation or force application.

For constant velocity pulling (cvel mode), the running integral over the pulling force in direction of the spring is recorded and can then later be used to compute the potential of mean force (PMF) by averaging over multiple independent trajectories along the same pulling path.
17.192.4 Restart, fix_modify, output, run start/stop, minimize info

The fix stores the direction of the spring, current pulling target distance and the running PMF to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify virial option is supported by this fix to add the contribution due to the added forces on atoms to both the global pressure and per-atom stress of the system via the compute pressure and compute stress/atom commands. The former can be accessed by thermodynamic output. The default setting for this fix is fix_modify virial no.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.

This fix computes a vector list of 7 quantities, which can be accessed by various output commands. The quantities in the vector are in this order: the x-, y-, and z-component of the pulling force, the total force in direction of the pull, the equilibrium distance of the spring, the distance between the two reference points, and finally the accumulated PMF (the sum of pulling forces times displacement).

The force is the total force on the group of atoms by the spring. In the case of the couple style, it is the force on the fix group (group-ID) or the negative of the force on the second group (group-ID2). The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.192.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

17.193.1 Syntax

```plaintext
fix ID group-ID smd/adjust_dt arg
```

- ID, group-ID are documented in `fix` command
- smd/adjust_dt = style name of this fix command
- arg = s_fact
  
  `s_fact` = safety factor

17.193.2 Examples

```plaintext
fix 1 all smd/adjust_dt 0.1
```

17.193.3 Description

The fix calculates a new stable time increment for use with the SMD time integrators.

The stable time increment is based on multiple conditions. For the SPH pair styles, a CFL criterion (Courant, Friedrichs & Lewy, 1928) is evaluated, which determines the speed of sound cannot propagate further than a typical spacing between particles within a single time step to ensure no information is lost. For the contact pair styles, a linear analysis of the pair potential determines a stable maximum time step.

This fix inquires the minimum stable time increment across all particles contained in the group for which this fix is defined. An additional safety factor `s_fact` is applied to the time increment.

See this PDF guide to use Smooth Mach Dynamics in LAMMPS.

17.193.4 Restart, fix_modify, output, run start/stop, minimize info

Currently, no part of MACHDYN supports restarting nor minimization.

17.193.5 Restrictions

This fix is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the `Build package` page for more info.

```

- ID, group-ID are documented in `fix` command
- smd/integrate_ulsph = style name of this fix command
- zero or more keyword/value pairs may be appended
- keyword = `adjust_radius` or `limit_velocity`

**adjust_radius values** = `adjust_radius_factor min_nn max_nn`  
`adjust_radius_factor` = factor which scale the smooth/kernel radius  
`min_nn` = minimum number of neighbors  
`max_nn` = maximum number of neighbors

**limit_velocity values** = `max_velocity`  
`max_velocity` = maximum allowed velocity.

17.195.2 Examples

```
fix 1 all smd/integrate_ulsph adjust_radius 1.02 25 50
fix 1 all smd/integrate_ulsph limit_velocity 1000
```

17.195.3 Description

The fix performs explicit time integration for particles which interact with the updated Lagrangian SPH pair style.  
See this PDF guide to using Smooth Mach Dynamics in LAMMPS.

The `adjust_radius` keyword activates dynamic adjustment of the per-particle SPH smoothing kernel radius such that the number of neighbors per particles remains within the interval `min_nn` to `max_nn`. The parameter `adjust_radius_factor` determines the amount of adjustment per timestep. Typical values are `adjust_radius_factor` =1.02, `min_nn` =15, and `max_nn` =20.

The `limit_velocity` keyword will control the velocity, scaling the norm of the velocity vector to `max_vel` in case it exceeds this velocity limit.
17.195.4 Restart, fix modify, output, run start/stop, minimize info

Currently, no part of MACHDYN supports restarting nor minimization. This fix has no outputs.

fix 2 tool smd/move_tri_surf *WIGGLE 20 20 10
fix 2 tool smd/move_tri_surf *ROTATE 0 0 0 5 2 1
```

17.196.3 Description

This fix applies only to rigid surfaces read from .STL files via fix `smd/wall_surface`. It updates position and velocity for the particles in the group each timestep without regard to forces on the particles. The rigid surfaces can thus be moved along simple trajectories during the simulation.

The *LINEAR style moves particles with the specified constant velocity vector $V = (V_x, V_y, V_z)$. This style also sets the velocity of each particle to $V = (V_x, V_y, V_z)$.

The *WIGGLE style moves particles in an oscillatory fashion. Particles are moved along $(v_x, v_y, v_z)$ with constant velocity until a displacement of max_travel is reached. Then, the velocity vector is reversed. This process is repeated.

The *ROTATE style rotates particles around a rotation axis $R = (R_x, R_y, R_z)$ that goes through a point $P = (P_x, P_y, P_z)$. The period of the rotation is also specified. This style also sets the velocity of each particle to $(\omega \times R_{perp})$ where $\omega$ is its angular velocity around the rotation axis and $R_{perp}$ is a perpendicular vector from the rotation axis to the particle.

See this PDF guide to using Smooth Mach Dynamics in LAMMPS.

17.196.4 Restart, fix_modify, output, run start/stop, minimize info

Currently, no part of MACHDYN supports restarting nor minimization. This fix has no outputs.

17.197 fix smd/setvel command

17.197.1 Syntax

```
fix ID group-ID smd/setvel vx vy vz keyword value ...
```

- ID, group-ID are documented in *fix* command
- smd/setvel = style name of this fix command
- vx,vy,vz = velocity component values
- any of vx,vy,vz can be a variable (see below)
- zero or more keyword/value pairs may be appended to args
- keyword = region
  
  region value = region-ID
  region-ID = ID of region particles must be in to have their velocities set

17.197.2 Examples

```
fix top_velocity top_group smd/setvel 1.0 0.0 0.0
```

17.197.3 Description

Set each component of velocity on each particle in the group to the specified values vx,vy,vz, regardless of the forces acting on the particle. This command can be used to impose velocity boundary conditions.

Any of the vx,vy,vz values can be specified as NULL which means do not alter the velocity component in that dimension. This fix is intended to be used together with a time integration fix.

Any of the 3 quantities defining the velocity components can be specified as an equal-style or atom-style variable, namely vx, vy, vz. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the force component.

Equal-style variables can specify formulas with various mathematical functions, and include *thermo_style* command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent velocity field.

Atom-style variables can specify the same formulas as equal-style variables but can also include per-atom values, such as atom coordinates. Thus it is easy to specify a spatially-dependent velocity field with optional time-dependence as well.

If the *region* keyword is used, the particle must also be in the specified geometric region in order to have its velocity set by this command.
17.197.4 Restart, fix_modify, output, run start/stop, minimize info

Currently, no part of MACHDYN supports restarting nor minimization. None of the fix_modify options are relevant to this fix.

This fix computes a global 3-vector of forces, which can be accessed by various output commands. This is the total force on the group of atoms. The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

17.197.5 Restrictions

This fix is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

17.198 fix smd/wall_surface command

17.198.1 Syntax

```plaintext
fix ID group-ID smd/wall_surface arg type mol-ID
```

- ID, group-ID are documented in fix command
- smd/wall_surface = style name of this fix command
- arg = file
  - file = file name of a triangular mesh in stl format
- type = particle type to be given to the new particles created by this fix
- mol-ID = molecule-ID to be given to the new particles created by this fix (must be >= 65535)

17.198.2 Examples

```plaintext
fix stl_surf all smd/wall_surface tool.stl 2 65535
```
17.198.3 Description

This fix creates reads a triangulated surface from a file in .STL format. For each triangle, a new particle is created which stores the barycenter of the triangle and the vertex positions. The radius of the new particle is that of the minimum circle which encompasses the triangle vertices.

The triangulated surface can be used as a complex rigid wall via the *smd/tri_surface* pair style. It is possible to move the triangulated surface via the *smd/move_tri_surf* fix style.

Immediately after a .STL file has been read, the simulation needs to be run for 0 timesteps in order to properly register the new particles in the system. See the “funnel_flow” example in the MACHDYN examples directory.

See this PDF guide to use Smooth Mach Dynamics in LAMMPS.

17.198.4 Restart, fix_modify, output, run start/stop, minimize info

Currently, no part of MACHDYN supports restarting nor minimization. This fix has no outputs.

17.198.5 Restrictions

This fix is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

The molecule ID given to the particles created by this fix have to be equal to or larger than 65535.

Within each .STL file, only a single triangulated object must be present, even though the STL format allows for the possibility of multiple objects in one file.

</tbody>
</table>

17.201.3 Description

Apply a spring force to a group of atoms or between two groups of atoms. This is useful for applying an umbrella force to a small molecule or lightly tethering a large group of atoms (e.g. all the solvent or a large molecule) to the center of the simulation box so that it does not wander away over the course of a long simulation. It can also be used to hold the centers of mass of two groups of atoms at a given distance or orientation with respect to each other.

The tether style attaches a spring between a fixed point $x,y,z$ and the center of mass of the fix group of atoms. The equilibrium position of the spring is $R_0$. At each timestep the distance $R$ from the center of mass of the group of atoms to the tethering point is computed, taking account of wrap-around in a periodic simulation box. A restoring force of magnitude $K (R - R_0) M_i / M$ is applied to each atom in the group where $K$ is the spring constant, $M_i$ is the mass of the atom, and $M$ is the total mass of all atoms in the group. Note that $K$ thus represents the spring constant for the total force on the group of atoms, not for a spring applied to each atom.

The couple style links two groups of atoms together. The first group is the fix group; the second is specified by group-ID2. The groups are coupled together by a spring that is at equilibrium when the two groups are displaced by a vector $x,y,z$ with respect to each other and at a distance $R_0$ from that displacement. Note that $x,y,z$ is the equilibrium displacement of group-ID2 relative to the fix group. Thus $(1,1,0)$ is a different spring than $(-1,-1,0)$. When the relative positions and distance between the two groups are not in equilibrium, the same spring force described above is applied to atoms in each of the two groups.

For both the tether and couple styles, any of the $x,y,z$ values can be specified as NULL which means do not include that dimension in the distance calculation or force application.

The first example above pulls the ligand towards the point $(0,0,0)$. The second example holds the ligand near the surface of a sphere of radius 5 around the point $(0,0,0)$. The third example holds the ligand a distance 3 away from the $z=2$ plane (on either side).

The fourth example holds 2 bilayers a distance 10 apart in $z$. For the last two examples, imagine a pore (a slab of atoms with a cylindrical hole cut out) oriented with the pore axis along $z$, and an ion moving within the pore. The fifth example holds the ion a distance of -20 below the $z = 0$ center plane of the pore (umbrella sampling). The last example holds the ion a distance 5 away from the pore axis (assuming the center-of-mass of the pore in $x,y$ is the pore axis).

Note: The center of mass of a group of atoms is calculated in “unwrapped” coordinates using atom image flags, which means that the group can straddle a periodic boundary. See the dump doc page for a discussion of unwrapped coordinates. It also means that a spring connecting two groups or a group and the tether point can cross a periodic boundary and its length be calculated correctly.
17.201.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify energy option is supported by this fix to add the energy stored in the spring to the global potential energy of the system as part of thermodynamic output. The default setting for this fix is fix_modify energy no.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the spring energy \( E = 0.5 \times K \times r^2 \).

This fix also computes global 4-vector which can be accessed by various output commands. The first 3 quantities in the vector are xyz components of the total force added to the group of atoms by the spring. In the case of the couple style, it is the force on the fix group (group-ID) or the negative of the force on the second group (group-ID2). The fourth quantity in the vector is the magnitude of the force added by the spring, as a positive value if \( (r-R_0) > 0 \) and a negative value if \( (r-R_0) < 0 \). This sign convention can be useful when using the spring force to compute a potential of mean force (PMF).

The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command.

**Note:** If you want the spring energy to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the fixModify energy option for this fix.

17.201.5 Restrictions

17.202 fix spring/chunk command

17.202.1 Syntax

```
fix ID group-ID spring/chunk K chunkID comID
```

- ID, group-ID are documented in fix command
- spring/chunk = style name of this fix command
- \( K \) = spring constant for each chunk (force/distance units)
• chunkID = ID of compute chunk/atom command
• comID = ID of compute com/chunk command

17.202.2 Examples

```
fix restrain all spring/chunk 100 chunkID comID
```

17.202.3 Description

Apply a spring force to the center-of-mass (COM) of chunks of atoms as defined by the compute chunk/atom command. Chunks can be molecules or spatial bins or other groupings of atoms. This is a way of tethering each chunk to its initial COM coordinates.

The chunkID is the ID of a compute chunk/atom command defined in the input script. It is used to define the chunks. The comID is the ID of a compute com/chunk command defined in the input script. It is used to compute the COMs of each chunk.

At the beginning of the first run or minimize command after this fix is defined, the initial COM of each chunk is calculated and stored as R0m, where M is the chunk number. Thereafter, at every timestep (or minimization iteration), the current COM of each chunk is calculated as Rm. A restoring force of magnitude K (Rm - R0m) Mi / Mm is applied to each atom in each chunk where K is the specified spring constant, Mi is the mass of the atom, and Mm is the total mass of all atoms in the chunk. Note that K thus represents the spring constant for the total force on each chunk of atoms, not for a spring applied to each atom.

17.202.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the locations of the initial per-chunk center of mass coordinates to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the fix continues in an uninterrupted fashion. Since this fix depends on an instance of compute chunk/atom it will check when reading the restart if the chunk still exists and will define the same number of chunks. The restart data is only applied when the number of chunks matches. Otherwise the center of mass coordinates are recomputed.

The fix_modify energy option is supported by this fix to add the energy stored in all the springs to the global potential energy of the system as part of thermodynamic output. The default setting for this fix is fix_modify energy no.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the energy of all the springs, i.e. 0.5 * K * r^2 per-spring.

The scalar value calculated by this fix is “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command.

Note: If you want the spring energies to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the fix_modify energy option for this fix.

fix spring, fix spring/self, fix spring/rg

17.202.7 Default

none

17.203 fix spring/rg command

17.203.1 Syntax

```plaintext
fix ID group-ID spring/rg K RG0
```

- ID, group-ID are documented in fix command
- spring/rg = style name of this fix command
- K = harmonic force constant (force/distance units)
- RG0 = target radius of gyration to constrain to (distance units)

if RG0 = NULL, use the current RG as the target value

17.203.2 Examples

```plaintext
fix 1 protein spring/rg 5.0 10.0
fix 2 micelle spring/rg 5.0 NULL
```

17.203.3 Description

Apply a harmonic restraining force to atoms in the group to affect their central moment about the center of mass (radius of gyration). This fix is useful to encourage a protein or polymer to fold/unfold and also when sampling along the radius of gyration as a reaction coordinate (i.e. for protein folding).

The radius of gyration is defined as RG in the first formula. The energy of the constraint and associated force on each atom is given by the second and third formulas, when the group is at a different RG than the target value RG0.

\[
RG^2 = \frac{1}{M} \sum_{i=1}^{N} m_i \left( x_i - \frac{1}{M} \sum_{j=1}^{N} m_j x_j \right)^2
\]

\[
E = K (R_G - R_{G0})^2
\]

\[
F_i = 2K \frac{m_i}{M} \left( 1 - \frac{R_{G0}}{R_G} \right) \left( x_i - \frac{1}{M} \sum_{j=1}^{N} m_j x_j \right)
\]
The \( (x_i - \text{center-of-mass}) \) term is computed taking into account periodic boundary conditions, \( m_i \) is the mass of the atom, and \( M \) is the mass of the entire group. Note that \( K \) is thus a force constant for the aggregate force on the group of atoms, not a per-atom force.

If \( R_{G0} \) is specified as NULL, then the RG of the group is computed at the time the fix is specified, and that value is used as the target.

### 17.203.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the currently used reference RG \( (R_{G0}) \) to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the fix continues in an uninterrupted fashion.

None of the fix_modify options are relevant to this fix.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the reference radius of gyration \( R_{G0} \) used by the fix. energy change due to this fix. The scalar value calculated by this fix is “intensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.

### 17.203.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

### 17.203.6 Related commands

fix spring, fix spring/self, fix drag, fix smd

### 17.203.7 Default

none

### 17.204 fix spring/self command

#### 17.204.1 Syntax

\[
\text{fix ID group-ID spring/self K dir}
\]

- ID, group-ID are documented in fix command
- spring/self = style name of this fix command
- K = spring constant (force/distance units)
- dir = xyz, xy, xz, yz, x, y, or z (optional, default: xyz)
17.204.2 Examples

```plaintext
fix tether boundary-atoms spring/self 10.0
fix zrest move spring/self 10.0 z
```

17.204.3 Description

Apply a spring force independently to each atom in the group to tether it to its initial position. The initial position for each atom is its location at the time the fix command was issued. At each timestep, the magnitude of the force on each atom is \(-Kr\), where \(r\) is the displacement of the atom from its current position to its initial position. The distance \(r\) correctly takes into account any crossings of periodic boundary by the atom since it was in its initial position.

With the (optional) dir flag, one can select in which direction the spring force is applied. By default, the restraint is applied in all directions, but it can be limited to the xy-, xz-, yz-plane and the x-, y-, or z-direction, thus restraining the atoms to a line or a plane, respectively.

17.204.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the original coordinates of tethered atoms to binary restart files, so that the spring effect will be the same in a restarted simulation. See the `read_restart` command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The `fix_modify energy` option is supported by this fix to add the energy stored in the per-atom springs to the global potential energy of the system as part of thermodynamic output. The default setting for this fix is `fix_modify energy no`. The `fix_modify respa` option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar which can be accessed by various output commands. The scalar is an energy which is the sum of the spring energy for each atom, where the per-atom energy is \(0.5 \times K \times r^2\). The scalar value calculated by this fix is “extensive”.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command.

The forces due to this fix are imposed during an energy minimization, invoked by the `minimize` command.

**Note:** If you want the per-atom spring energy to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the `fix_modify energy` option for this fix.

fix 1 srd srd 10 big 1.0 0.25 482984
fix 1 srd srd 10 big 0.5 0.25 482984 collision slip search 0.5

17.205.3 Description

Treat a group of particles as stochastic rotation dynamics (SRD) particles that serve as a background solvent when interacting with big (colloidal) particles in groupbig-ID. The SRD formalism is described in (Hecht). The key idea behind using SRD particles as a cheap coarse-grained solvent is that SRD particles do not interact with each other, but only with the solute particles, which in LAMMPS can be spheroids, ellipsoids, or line segments, or triangles, or rigid bodies containing multiple spheroids or ellipsoids or line segments or triangles. The collision and rotation properties of the model imbue the SRD particles with fluid-like properties, including an effective viscosity. Thus simulations with large solute particles can be run more quickly, to measure solute properties like diffusivity and viscosity in a background fluid. The usual LAMMPS fixes for such simulations, such as fix deform, fix viscosity, and fix nvt/sllod, can be used in conjunction with the SRD model.

For more details on how the SRD model is implemented in LAMMPS, this paper describes the implementation and usage of pure SRD fluids. This paper, which is nearly complete, describes the implementation and usage of mixture systems (solute particles in an SRD fluid). See the examples/srddirectory for sample input scripts using SRD particles in both settings.

This fix does two things:

1. It advects the SRD particles, performing collisions between SRD and big particles or walls every timestep, imparting force and torque to the big particles. Collisions also change the position and velocity of SRD particles.
2. It resets the velocity distribution of SRD particles via random rotations every N timesteps.

SRD particles have a mass, temperature, characteristic timestep \( dt_{SRD} \), and mean free path between collisions (\( \lambda \)). The fundamental equation relating these 4 quantities is

\[
\lambda = dt_{SRD} \sqrt{\frac{k_B T_{SRD}}{m}}
\]

The mass \( m \) of SRD particles is set by the mass command elsewhere in the input script. The SRD timestep \( dt_{SRD} \) is N times the step \( dt \) defined by the timestep command. Big particles move in the normal way via a time integration fix with a short timestep \( dt \). SRD particles advect with a large timestep \( dt_{SRD} \geq dt \).

If the lambda keyword is not specified, the SRD temperature \( T_{SRD} \) is used in the above formula to compute \( \lambda \). If the lambda keyword is specified, then the Tsrd setting is ignored and the above equation is used to compute the SRD temperature.

The characteristic length scale for the SRD fluid is set by hgrid which is used to bin SRD particles for purposes of resetting their velocities. Normally hgrid is set to be 1/4 of the big particle diameter or smaller, to adequately resolve fluid properties around the big particles.

\( \lambda \) cannot be smaller than 0.6 * hgrid, else an error is generated (unless the shift keyword is used, see below). The velocities of SRD particles are bounded by Vmax, which is set so that an SRD particle will not advect further than \( D_{max} = 4\lambda \) in \( dt_{SRD} \). This means that roughly speaking, \( D_{max} \) should not be larger than a big particle diameter, else SRDs may pass through big particles without colliding. A warning is generated if this is the case.
Collisions between SRD particles and big particles or walls are modeled as a lightweight SRD point particle hitting a heavy big particle of given diameter or a wall at a point on its surface and bouncing off with a new velocity. The collision changes the momentum of the SRD particle. It imparts a force and torque to the big particle. It imparts a force to a wall. Static or moving SRD walls are setup via the `fix wall/srd` command. For the remainder of this doc page, a collision of an SRD particle with a wall can be viewed as a collision with a big particle of infinite radius and mass.

The `collision` keyword sets the style of collisions. The `slip` style means that the tangential component of the SRD particle momentum is preserved. Thus a force is imparted to a big particle, but no torque. The normal component of the new SRD velocity is sampled from a Gaussian distribution at temperature $T_{srd}$. For the `noslip` style, both the normal and tangential components of the new SRD velocity are sampled from a Gaussian distribution at temperature $T_{srd}$. Additionally, a new tangential direction for the SRD velocity is chosen randomly. This collision style imparts torque to a big particle. Thus a time integrator `fix` that rotates the big particles appropriately should be used.

The `overlap` keyword should be set to `yes` if two (or more) big particles can ever overlap. This depends on the pair potential interaction used for big-big interactions, or could be the case if multiple big particles are held together as rigid bodies via the `fix rigid` command. If the `overlap` keyword is `no` and big particles do in fact overlap, then SRD/big collisions can generate an error if an SRD ends up inside two (or more) big particles at once. How this error is treated is determined by the `inside` keyword. Running with `overlap` set to `no` allows for faster collision checking, so it should only be set to `yes` if needed.

The `inside` keyword determines how a collision is treated if the computation determines that the timestep started with the SRD particle already inside a big particle. If the setting is `error` then this generates an error message and LAMMPS stops. If the setting is `warn` then this generates a warning message and the code continues. If the setting is `ignore` then no message is generated. One of the output quantities logged by the `fix` (see below) tallies the number of such events, so it can be monitored. Note that once an SRD particle is inside a big particle, it may remain there for several steps until it drifts outside the big particle.

The `exact` keyword determines how accurately collisions are computed. A setting of `yes` computes the time and position of each collision as SRD and big particles move together. A setting of `no` estimates the position of each collision based on the end-of-timestep positions of the SRD and big particle. If `overlap` is set to `yes`, the setting of the `exact` keyword is ignored since time-accurate collisions are needed.

The `radius` keyword scales the effective size of big particles. If big particles will overlap as they undergo dynamics, then this keyword can be used to scale down their effective collision radius by an amount `rfactor`, so that SRD particle will only collide with one big particle at a time. For example, in a Lennard-Jones system at a temperature of 1.0 (in reduced LJ units), the minimum separation between two big particles is as small as about 0.88 sigma. Thus an `rfactor` value of 0.85 should prevent dual collisions.

The `bounce` keyword can be used to limit the maximum number of collisions an SRD particle undergoes in a single timestep as it bounces between nearby big particles. Note that if the limit is reached, the SRD can be left inside a big particle. A setting of 0 is the same as no limit.

There are 2 kinds of bins created and maintained when running an SRD simulation. The first are “SRD bins” which are used to bin SRD particles and reset their velocities, as discussed above. The second are “search bins” which are used to identify SRD/big particle collisions.

The `search` keyword can be used to choose a search bin size for identifying SRD/big particle collisions. The default is to use the `hgrid` parameter for SRD bins as the search bin size. Choosing a smaller or large value may be more efficient, depending on the problem. But, in a statistical sense, it should not change the simulation results.

The `cubic` keyword can be used to generate an error or warning when the bin size chosen by LAMMPS creates SRD bins that are non-cubic or different than the requested value of `hgrid` by a specified `tolerance`. Note that using non-cubic SRD bins can lead to undetermined behavior when rotating the velocities of SRD particles, hence LAMMPS tries to protect you from this problem.

17.205. `fix srd` command 1555
LAMMPS attempts to set the SRD bin size to exactly \textit{hgrid}. However, there must be an integer number of bins in each dimension of the simulation box. Thus the actual bin size will depend on the size and shape of the overall simulation box. The actual bin size is printed as part of the SRD output when a simulation begins.

If the actual bin size in non-cubic by an amount exceeding the tolerance, an error or warning is printed, depending on the style of the \textit{cubic} keyword. Likewise, if the actual bin size differs from the requested \textit{hgrid} value by an amount exceeding the tolerance, then an error or warning is printed. The \textit{tolerance} is a fractional difference. E.g. a tolerance setting of 0.01 on the shape means that if the ratio of any 2 bin dimensions exceeds (1 +/- tolerance) then an error or warning is generated. Similarly, if the ratio of any bin dimension with \textit{hgrid} exceeds (1 +/- tolerance), then an error or warning is generated.

\textbf{Note:} The \textit{fix srd} command can be used with simulations where the size and/or shape of the simulation box changes. This can be due to non-periodic boundary conditions or the use of fixes such as the \textit{fix deform} or \textit{fix wall/srd} commands to impose a shear on an SRD fluid or an interaction with an external wall. If the box size changes then the size of SRD bins must be recalculated every reneighboring. This is not necessary if only the box shape changes. This re-binning is always done so as to fit an integer number of bins in the current box dimension, whether it be a fixed, shrink-wrapped, or periodic boundary, as set by the \textit{boundary} command. If the box size or shape changes, then the size of the search bins must be recalculated every reneighboring. Note that changing the SRD bin size may alter the properties of the SRD fluid, such as its viscosity.

The \textit{shift} keyword determines whether the coordinates of SRD particles are randomly shifted when binned for purposes of rotating their velocities. When no shifting is performed, SRD particles are binned and the velocity distribution of the set of SRD particles in each bin is adjusted via a rotation operator. This is a statistically valid operation if SRD particles move sufficiently far between successive rotations. This is determined by their mean-free path \( \lambda \). If \( \lambda \) is less than 0.6 of the SRD bin size, then shifting is required. A shift means that all of the SRD particles are shifted by a vector whose coordinates are chosen randomly in the range \([-1/2 \text{ bin size}, 1/2 \text{ bin size}]\). Note that all particles are shifted by the same vector. The specified random number \textit{shiftseed} is used to generate these vectors. This operation sufficiently randomizes which SRD particles are in the same bin, even if \( \lambda \) is small.

If the \textit{shift} flag is set to \textit{no}, then no shifting is performed, but bin data will be communicated if bins overlap processor boundaries. An error will be generated if \( \lambda < 0.6 \) of the SRD bin size. If the \textit{shift} flag is set to \textit{possible}, then shifting is performed only if \( \lambda < 0.6 \) of the SRD bin size. A warning is generated to let you know this is occurring. If the \textit{shift} flag is set to \textit{yes} then shifting is performed regardless of the magnitude of \( \lambda \). Note that the \textit{shiftseed} is not used if the \textit{shift} flag is set to \textit{no}, but must still be specified.

Note that shifting of SRD coordinates requires extra communication, hence it should not normally be enabled unless required.

The \textit{tstat} keyword will thermostat the SRD particles to the specified \( T_{srd} \). This is done every \( N \) timesteps, during the velocity rotation operation, by rescaling the thermal velocity of particles in each SRD bin to the desired temperature. If there is a streaming velocity associated with the system, e.g. due to use of the \textit{fix deform} command to perform a simulation undergoing shear, then that is also accounted for. The mean velocity of each bin of SRD particles is set to the position-dependent streaming velocity, based on the coordinates of the center of the SRD bin. Note that collisions of SRD particles with big particles or walls has a thermostatting effect on the colliding particles, so it may not be necessary to thermostat the SRD particles on a bin by bin basis in that case. Also note that for streaming simulations, if no thermostatting is performed (the default), then it may take a long time for the SRD fluid to come to equilibrium with a velocity profile that matches the simulation box deformation.

The \textit{rescale} keyword enables rescaling of an SRD particle’s velocity if it would travel more than 4 mean-free paths in an SRD timestep. If an SRD particle exceeds this velocity it is possible it will be lost when migrating to other processors or that collisions with big particles will be missed, either of which will generate errors. Thus the safest mode is to run with rescaling enabled. However rescaling removes kinetic energy from the system (the particle’s velocity is reduced). The latter will not typically be a problem if thermostatting is enabled via the \textit{tstat} keyword or if SRD collisions with big particles or walls effectively thermostat the system. If you wish to turn off rescaling (on is the default), e.g. for a pure SRD system with no thermostatting so that the temperature does not decline over time, the \textit{rescale} keyword can
be used. The no value turns rescaling off during collisions and the per-bin velocity rotation operation. The collide and rotate values turn it on for one of the operations and off for the other.

**Note:** This fix is normally used for simulations with a huge number of SRD particles relative to the number of big particles, e.g. 100 to 1. In this scenario, computations that involve only big particles (neighbor list creation, communication, time integration) can slow down dramatically due to the large number of background SRD particles.

Three other input script commands will largely overcome this effect, speeding up an SRD simulation by a significant amount. These are the atom_modify first, neigh_modify include, and comm_modify group commands. Each takes a group-ID as an argument, which in this case should be the group-ID of the big solute particles.

Additionally, when a pair_style for big/big particle interactions is specified, the pair_coeff command should be used to turn off big/SRD interactions, e.g. by setting their epsilon or cutoff length to 0.0.

The “delete_atoms overlap” command may be useful in setting up an SRD simulation to insure there are no initial overlaps between big and SRD particles.

17.205.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix.

This fix tabulates several SRD statistics which are stored in a vector of length 12, which can be accessed by various output commands. The vector values calculated by this fix are “intensive”, meaning they do not scale with the size of the simulation. Technically, the first 8 do scale with the size of the simulation, but treating them as intensive means they are not scaled when printed as part of thermodynamic output.

These are the 12 quantities. All are values for the current timestep, except for quantity 5 and the last three, each of which are cumulative quantities since the beginning of the run.

- (1) # of SRD/big collision checks performed
- (2) # of SRDs which had a collision
- (3) # of SRD/big collisions (including multiple bounces)
- (4) # of SRD particles inside a big particle
- (5) # of SRD particles whose velocity was rescaled to be < Vmax
- (6) # of bins for collision searching
- (7) # of bins for SRD velocity rotation
- (8) # of bins in which SRD temperature was computed
- (9) SRD temperature
- (10) # of SRD particles which have undergone max # of bounces
- (11) max # of bounces any SRD particle has had in a single step
- (12) # of reneighborings due to SRD particles moving too far

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.
17.205.5 Restrictions

This command can only be used if LAMMPS was built with the SRD package. See the Build package doc page for more info.

17.205.6 Related commands

fix wall/srd

17.205.7 Default

The option defaults are: \( \lambda \) is inferred from \( T_{srd} \), collision = noslip, overlap = no, inside = error, exact = yes, radius = 1.0, bounce = 0, search = hgrid, cubic = error 0.01, shift = no, tstat = no, and rescale = yes.

(Hecht) Hecht, Harting, Ihle, Herrmann, Phys Rev E, 72, 011408 (2005).

17.206 fix store/force command

17.206.1 Syntax

```
fix ID group-ID store/force
```

- ID, group-ID are documented in fix command
- store/force = style name of this fix command

17.206.2 Examples

```
fix 1 all store/force
```

17.206.3 Description

Store the forces on atoms in the group at the point during each timestep when the fix is invoked, as described below. This is useful for storing forces before constraints or other boundary conditions are computed which modify the forces, so that unmodified forces can be written to a dump file or accessed by other output commands that use per-atom quantities.

This fix is invoked at the point in the velocity-Verlet timestepping immediately after pair, bond, angle, dihedral, improper, and long-range forces have been calculated. It is the point in the timestep when various fixes that compute constraint forces are calculated and potentially modify the force on each atom. Examples of such fixes are fix shake, fix wall, and fix indent.

Note: The order in which various fixes are applied which operate at the same point during the timestep, is the same as the order they are specified in the input script. Thus normally, if you want to store per-atom forces due to force field interactions, before constraints are applied, you should list this fix first within that set of fixes, i.e. before other fixes
that apply constraints. However, if you wish to include certain constraints (e.g. fix shake) in the stored force, then it could be specified after some fixes and before others.

17.206.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. This fix produces a per-atom array which can be accessed by various output commands. The number of columns for each atom is 3, and the columns store the x,y,z forces on each atom. The per-atom values be accessed on any timestep. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

fix 1 all store/state 0 x y z
fix 1 all store/state 0 xu yu zu com yes
fix 2 all store/state 1000 vx vy vz
```

17.207.3 Description

Define a fix that stores attributes for each atom in the group at the time the fix is defined. If \( N \) is 0, then the values are never updated, so this is a way of archiving an atom attribute at a given time for future use in a calculation or output. See the discussion of output commands that take fixes as inputs.

If \( N \) is not zero, then the attributes will be updated every \( N \) steps.

**Note:** Actually, only atom attributes specified by keywords like \( xu \) or \( vy \) or \( radius \) are initially stored immediately at the point in your input script when the fix is defined. Attributes specified by a compute, fix, or variable are not initially stored until the first run following the fix definition begins. This is because calculating those attributes may require quantities that are not defined in between runs.
The list of possible attributes is the same as that used by the dump custom command, which describes their meaning.

If the com keyword is set to yes then the xu, yu, and zu inputs store the position of each atom relative to the center-of-mass of the group of atoms, instead of storing the absolute position.

The requested values are stored in a per-atom vector or array as discussed below. Zeroes are stored for atoms not in the specified group.

17.207.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the per-atom values it stores to binary restart files, so that the values can be restored when a simulation is restarted. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

Warning: When reading data from a restart file, this fix command has to be specified exactly the same way as before. LAMMPS will only check whether a fix is of the same style and has the same fix ID and in case of a match will then try to initialize the fix with the data stored in the binary restart file. If the fix store/state command does not match exactly, data can be corrupted or LAMMPS may crash.

None of the fix_modify options are relevant to this fix.

If a single input is specified, this fix produces a per-atom vector. If multiple inputs are specified, a per-atom array is produced where the number of columns for each atom is the number of inputs. These can be accessed by various output commands. The per-atom values be accessed on any timestep.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.207.5 Restrictions

none

17.207.6 Related commands

17.208 fix temp/berendsen command

17.208.1 Syntax

```
fix ID group-ID temp/berendsen Tstart Tstop Tdamp
```

- ID, group-ID are documented in fix command
- temp/berendsen = style name of this fix command
• Tstart,Tstop = desired temperature at start/end of run

  Tstart can be a variable (see below)

• Tdamp = temperature damping parameter (time units)

### 17.208.2 Examples

```
fix 1 all temp/berendsen 300.0 300.0 100.0
```

### 17.208.3 Description

Reset the temperature of a group of atoms by using a Berendsen thermostat (Berendsen), which rescales their velocities every timestep.

The thermostat is applied to only the translational degrees of freedom for the particles, which is an important consideration for finite-size particles which have rotational degrees of freedom are being thermostatted with this fix. The translational degrees of freedom can also have a bias velocity removed from them before thermostatting takes place; see the description below.

The desired temperature at each timestep is a ramped value during the run from $T_{start}$ to $T_{stop}$. The $Tdamp$ parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 100.0 means to relax the temperature in a timespan of (roughly) 100 time units (tau or fs or ps - see the units command).

$T_{start}$ can be specified as an equal-style variable. In this case, the $T_{stop}$ setting is ignored. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the target temperature.

**Note:** This thermostat will generate an error if the current temperature is zero at the end of a timestep. It cannot rescale a zero temperature.

Equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent temperature.

**Note:** Unlike the fix nvt command which performs Nose/Hoover thermostatting AND time integration, this fix does NOT perform time integration. It only modifies velocities to effect thermostatting. Thus you must use a separate time integration fix, like fix nve to actually update the positions of atoms using the modified velocities. Likewise, this fix should not normally be used on atoms that also have their temperature controlled by another fix - e.g. by fix nvt or fix langevin commands.

See the Howto thermostat page for a discussion of different ways to compute temperature and perform thermostatting.

This fix computes a temperature each timestep. To do this, the fix creates its own compute of style “temp”, as if this command had been issued:

```
compute fix-ID_temp group-ID temp
```

See the compute temp command for details. Note that the ID of the new compute is the fix-ID + underscore + “temp”, and the group for the new compute is the same as the fix group.
Note that this is NOT the compute used by thermodynamic output (see the \texttt{thermo\_style} command) with ID = \texttt{thermo\_temp}. This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via the \texttt{compute\_modify} command or print this temperature during thermodynamic output via the \texttt{thermo\_style custom} command using the appropriate compute-ID. It also means that changing attributes of \texttt{thermo\_temp} will have no effect on this fix.

Like other fixes that perform thermostatting, this fix can be used with \texttt{compute commands} that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial \texttt{region}, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the \texttt{fix\_modify} command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual \texttt{compute temp commands} to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

\textbf{17.208.4 Restart, fix\_modify, output, run start/stop, minimize info}

This fix writes the cumulative global energy change to \texttt{binary restart files}. See the \texttt{read\_restart} command for info on how to re-specify a fix in an input script that reads a restart file, so that the fix continues in an uninterrupted fashion.

The \texttt{fix\_modify temp} option is supported by this fix. You can use it to assign a temperature \texttt{compute} you have defined to this fix which will be used in its thermostatting procedure, as described above. For consistency, the group used by this fix and by the compute should be the same.

The cumulative energy change in the system imposed by this fix is included in the \texttt{thermodynamic output} keywords \texttt{ecouple} and \texttt{econserv}. See the \texttt{thermo\_style} doc page for details.

This fix computes a global scalar which can be accessed by various \texttt{output commands}. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

This fix can ramp its target temperature over multiple runs, using the \texttt{start} and \texttt{stop} keywords of the \texttt{run} command. See the \texttt{run} command for details of how to do this.

This fix is not invoked during \texttt{energy minimization}.

\textbf{17.208.5 Restrictions}

This fix can be used with dynamic groups as defined by the \texttt{group} command. Likewise it can be used with groups to which atoms are added or deleted over time, e.g. a deposition simulation. However, the conservation properties of the thermostat and barostat are defined for systems with a static set of atoms. You may observe odd behavior if the atoms in a group vary dramatically over time or the atom count becomes very small.

- ID, group-ID are documented in fix command
- temp/csvr or temp/cslld = style name of this fix command
- Tstart, Tstop = desired temperature at start/end of run

Tstart can be a variable (see below)

- Tdamp = temperature damping parameter (time units)
- seed = random number seed to use for white noise (positive integer)

17.210.2 Examples

```
fix 1 all temp/csvr 300.0 300.0 100.0 54324
fix 1 all temp/cslld 100.0 300.0 10.0 123321
```

17.210.3 Description

Adjust the temperature with a canonical sampling thermostat that uses global velocity rescaling with Hamiltonian dynamics (temp/csvr) (Bussi1), or Langevin dynamics (temp/cslld) (Bussi2). In the case of temp/csvr the thermostat is similar to the empirical Berendsen thermostat in temp/berendsen, but chooses the actual scaling factor from a suitably chosen (gaussian) distribution rather than having it determined from the time constant directly. In the case of temp/cslld the velocities are updated to a linear combination of the current velocities with a gaussian distribution of velocities at the desired temperature. Both thermostats are applied every timestep.

The thermostat is applied to only the translational degrees of freedom for the particles, which is an important consideration for finite-size particles which have rotational degrees of freedom which are being thermostatted with these fixes. The translational degrees of freedom can also have a bias velocity removed from them before thermostating takes place; see the description below.

The desired temperature at each timestep is a ramped value during the run from Tstart to Tstop. The Tdamp parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 100.0 means to relax the temperature in a timespan of (roughly) 100 time units (tau or fs or ps - see the units command).
$T_{\text{start}}$ can be specified as an equal-style variable. In this case, the $T_{\text{stop}}$ setting is ignored. If the value is a variable, it should be specified as $v\_\text{name}$, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the target temperature.

Equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent temperature.

**Note:** Unlike the fix nvt command which performs Nose/Hoover thermostatting AND time integration, these fixes do NOT perform time integration. They only modify velocities to effect thermostatting. Thus you must use a separate time integration fix, like fix nve to actually update the positions of atoms using the modified velocities. Likewise, these fixes should not normally be used on atoms that also have their temperature controlled by another fix - e.g. by fix nvt or fix langevin commands.

See the *Howto thermostat* page for a discussion of different ways to compute temperature and perform thermostatting. These fixes compute a temperature each timestep. To do this, the fix creates its own compute of style “temp”, as if this command had been issued:

```
compute fix-ID_temp group-ID temp
```

See the compute temp command for details. Note that the ID of the new compute is the fix-ID + underscore + “temp”, and the group for the new compute is the same as the fix group.

Note that this is NOT the compute used by thermodynamic output (see the thermo_style command) with ID = thermo_temp. This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via the compute_modify command or print this temperature during thermodynamic output via the thermo_style custom command using the appropriate compute-ID. It also means that changing attributes of thermo_temp will have no effect on this fix.

Like other fixes that perform thermostatting, this fix can be used with compute commands that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial region, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the fix_modify command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual compute temp commands to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

An important feature of these thermostats is that they have an associated effective energy that is a constant of motion. The effective energy is the total energy (kinetic + potential) plus the accumulated kinetic energy changes due to the thermostat. The latter quantity is the global scalar computed by these fixes. This feature is useful to check the integration of the equations of motion against discretization errors. In other words, the conservation of the effective energy can be used to choose an appropriate integration timestep. This is similar to the usual paradigm of checking the conservation of the total energy in the microcanonical ensemble.
17.210.4 Restart, fix_modify, output, run start/stop, minimize info

These fixes write the cumulative global energy change and the random number generator states to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the selected fix continues in an uninterrupted fashion. The random number generator state can only be restored when the number of processors remains unchanged from what is recorded in the restart file.

The fix_modify temp option is supported by these fixes. You can use it to assign a temperature compute you have defined to these fixes which will be used in its thermostating procedure, as described above. For consistency, the group used by these fixes and by the compute should be the same.

The cumulative energy change in the system imposed by these fixes is included in the thermodynamic output keywords ecouple and econserve. See the thermo_style doc page for details.

These fixes compute a global scalar which can be accessed by various output commands. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

These fixes can ramp their target temperature over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

These fixes are not invoked during energy minimization.

17.210.5 Restrictions

Fix temp/csld is not compatible with fix shake.

These fixes are part of the EXTRA-FIX package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

These fixes can be used with dynamic groups as defined by the group command. Likewise it can be used with groups to which atoms are added or deleted over time, e.g. a deposition simulation. However, the conservation properties of the thermostat and barostat are defined for systems with a static set of atoms. You may observe odd behavior if the atoms in a group vary dramatically over time or the atom count becomes very small.

17.211 fix temp/rescale command

17.211.1 Syntax

`fix ID group-ID temp/rescale N Tstart Tstop window fraction`

- ID, group-ID are documented in `fix` command
- `temp/rescale` = style name of this fix command
- `N` = perform rescaling every `N` steps
- `Tstart, Tstop` = desired temperature at start/end of run (temperature units)
  
  `Tstart` can be a variable (see below)

- `window` = only rescale if temperature is outside this window (temperature units)
- `fraction` = rescale to target temperature by this fraction

17.211.2 Examples

```
fix 3 flow temp/rescale 100 1.0 1.1 0.02 0.5
fix 3 boundary temp/rescale 1 1.0 1.5 0.05 1.0
fix 3 boundary temp/rescale 1 1.0 1.5 0.05 1.0
```

17.211.3 Description

Reset the temperature of a group of atoms by explicitly rescaling their velocities.

The rescaling is applied to only the translational degrees of freedom for the particles, which is an important consideration if finite-size particles which have rotational degrees of freedom are being thermostatted with this fix. The translational degrees of freedom can also have a bias velocity removed from them before thermostatting takes place; see the description below.

Rescaling is performed every N timesteps. The target temperature is a ramped value between the `Tstart` and `Tstop` temperatures at the beginning and end of the run.

**Note:** This thermostat will generate an error if the current temperature is zero at the end of a timestep it is invoked on. It cannot rescale a zero temperature.

`Tstart` can be specified as an equal-style `variable`. In this case, the `Tstop` setting is ignored. If the value is a variable, it should be specified as v_name, where name is the variable name. In this case, the variable will be evaluated each timestep, and its value used to determine the target temperature.

Equal-style variables can specify formulas with various mathematical functions, and include `thermo_style` command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent temperature.

Rescaling is only performed if the difference between the current and desired temperatures is greater than the `window` value. The amount of rescaling that is applied is a `fraction` (from 0.0 to 1.0) of the difference between the actual and desired temperature. E.g. if `fraction = 1.0`, the temperature is reset to exactly the desired value.
**Note:** Unlike the `fix nvt` command which performs Nose/Hoover thermostatting AND time integration, this fix does NOT perform time integration. It only modifies velocities to effect thermostatting. Thus you must use a separate time integration fix, like `fix nve` to actually update the positions of atoms using the modified velocities. Likewise, this fix should not normally be used on atoms that also have their temperature controlled by another fix - e.g. by `fix nvt` or `fix langevin` commands.

See the [Howto thermostat](#) page for a discussion of different ways to compute temperature and perform thermostatting. This fix computes a temperature each timestep. To do this, the fix creates its own compute of style “temp”, as if one of this command had been issued:

```plaintext
compute fix-ID_temp group-ID temp
```

See the `compute temp` for details. Note that the ID of the new compute is the fix-ID + underscore + “temp”, and the group for the new compute is the same as the fix group.

Note that this is NOT the compute used by thermodynamic output (see the `thermo_style` command) with ID = `thermo_temp`. This means you can change the attributes of this fix’s temperature (e.g. its degrees-of-freedom) via the `compute_modify` command or print this temperature during thermodynamic output via the `thermo_style custom` command using the appropriate compute-ID. It also means that changing attributes of `thermo_temp` will have no effect on this fix.

Like other fixes that perform thermostatting, this fix can be used with `compute commands` that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial `region`, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the `fix_modify` command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual `compute temp commands` to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

---

**17.21.1.4 Restart, fix_modify, output, run start/stop, minimize info**

This fix writes the cumulative global energy change to `binary restart files`. See the `read_restart` command for info on how to re-specify a fix in an input script that reads a restart file, so that the fix continues in an uninterrupted fashion.

The `fix_modify temp` option is supported by this fix. You can use it to assign a temperature `compute` you have defined to this fix which will be used in its thermostatting procedure, as described above. For consistency, the group used by this fix and by the compute should be the same.

The cumulative energy change in the system imposed by this fix is included in the `thermodynamic output` keywords `ecouple` and `econserve`. See the `thermo_style` doc page for details.

This fix computes a global scalar which can be accessed by various `output commands`. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

This fix can ramp its target temperature over multiple runs, using the `start` and `stop` keywords of the `run` command. See the `run` command for details of how to do this.

This fix is not invoked during `energy minimization`.

```

### 17.213.3 Description

Perform uniform-acceptance force-bias Monte Carlo (fbMC) simulations, using the time-stamped force-bias Monte Carlo (tfMC) algorithm described in [Mees] and [Bal].

One successful use case of force-bias Monte Carlo methods is that they can be used to extend the time scale of atomistic simulations, in particular when long time scale relaxation effects must be considered; some interesting examples are given in the review by [Neyts]. An example of a typical use case would be the modelling of chemical vapor deposition (CVD) processes on a surface, in which impacts by gas-phase species can be performed using MD, but subsequent relaxation of the surface is too slow to be done using MD only. Using tfMC can allow for a much faster relaxation of the surface, so that higher fluxes can be used, effectively extending the time scale of the simulation. (Such an alternating simulation approach could be set up using a `loop`.)

The initial version of tfMC algorithm in [Mees] contained an estimation of the effective time scale of such a simulation, but it was later shown that the speed-up one can gain from a tfMC simulation is system- and process-dependent, ranging from none to several orders of magnitude. In general, solid-state processes such as (re)crystallization or growth can be accelerated by up to two or three orders of magnitude, whereas diffusion in the liquid phase is not accelerated at all. The observed pseudodynamics when using the tfMC method is not the actual dynamics one would obtain using MD, but the relative importance of processes can match the actual relative dynamics of the system quite well, provided `Delta` is chosen with care. Thus, the system’s equilibrium is reached faster than in MD, along a path that is generally roughly similar to a typical MD simulation (but not necessarily so). See [Bal] for details.

Each step, all atoms in the selected group are displaced using the stochastic tfMC algorithm, which is designed to sample the canonical (NVT) ensemble at the temperature `Temp`. Although tfMC is a Monte Carlo algorithm and thus strictly speaking does not perform time integration, it is similar in the sense that it uses the forces on all atoms in order to update their positions. Therefore, it is implemented as a time integration fix, and no other fixes of this type (such as `fix nve`) should be used at the same time. Because velocities do not play a role in this kind of Monte Carlo simulations, instantaneous temperatures as calculated by `temperature computes` or `thermodynamic output` have no meaning: the only relevant temperature is the sampling temperature `Temp`. Similarly, performing tfMC simulations does not require setting a `timestep` and the `simulated time` as calculated by LAMMPS is meaningless.

The critical parameter determining the success of a tfMC simulation is `Delta`, the maximal displacement length of the lightest element in the system: the larger it is, the longer the effective time scale of the simulation will be (there is an approximately quadratic dependence). However, `Delta` must also be chosen sufficiently small in order to comply with detailed balance; in general values between 5 and 10 % of the nearest neighbor distance are found to be a good choice. For a more extensive discussion with specific examples, please refer to [Bal], which also describes how the code calculates element-specific maximal displacements from `Delta`, based on the fourth root of their mass.

Because of the uncorrelated movements of the atoms, the center-of-mass of the fix group will not necessarily be stationary, just like its orientation. When the `com` keyword is used, all atom positions will be shifted (after every tfMC iteration) in order to fix the position of the center-of-mass along the included directions, by setting the corresponding flag to 1. The `rot` keyword does the same for the rotational component of the tfMC displacements after every iteration.

**Note:** the `com` and `rot` keywords should not be used if an external force is acting on the specified fix group, along the included directions. This can be either a true external force (e.g. through `fix wall`) or forces due to the interaction with atoms not included in the fix group. This is because in such cases, translations or rotations of the fix group could be induced by these external forces, and removing them will lead to a violation of detailed balance.
17.213.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

None of the fix_modify options are relevant to this fix.

This fix is not invoked during energy minimization.

17.213.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

This fix is not compatible with fix shake.

17.215.3 Description

These commands are variants of the Nose-Hoover fix styles `fix nvt` and `fix npt` for thermalized Drude polarizable models. They apply temperature-grouped Nose-Hoover thermostat (TGNH) proposed by (Son). When there are fast vibrational modes with frequencies close to Drude oscillators (e.g. double bonds or out-of-plane torsions), this thermostat can provide better kinetic energy equipartitioning.

The difference between TGNH and the original Nose-Hoover thermostat is that, TGNH separates the kinetic energy of the group into three contributions: molecular center of mass (COM) motion, motion of COM of atom-Drude pairs or non-polarizable atoms relative to molecular COM, and relative motion of atom-Drude pairs. An independent Nose-Hoover chain is applied to each type of motion. The temperatures for these three types of motion are denoted as molecular translational temperature \( T_M \), real atomic temperature \( T_R \) and Drude temperature \( T_D \), which are defined in terms of their associated degrees of freedom (DOF):

\[
T_M = \frac{\sum_{i} N_{mol} M_i V_i^2}{3 \left( N_{mol} - \frac{N_{mol}}{N_{mol,sys}} \right) k_B}
\]

\[
T_R = \frac{\sum_{i} N_{real} m_i (v_i - v_{M,i})^2}{(N_{DOF} - 3 N_{mol} + 3 \frac{N_{mol}}{N_{mol,sys}} - 3 N_{drude}) k_B}
\]

\[
T_D = \frac{\sum_{i} N_{drude} m_i' v_i'^2}{3 N_{drude} k_B}
\]

Here \( N_{mol} \) and \( N_{mol,sys} \) are the numbers of molecules in the group and in the whole system, respectively. \( N_{real} \) is the number of atom-Drude pairs and non-polarizable atoms in the group. \( N_{drude} \) is the number of Drude particles in the group. \( N_{DOF} \) is the DOF of the group. \( M_i \) and \( V_i \) are the mass and the COM velocity of the i-th molecule. \( m_i \) is the mass of the i-th atom-Drude pair or non-polarizable atom. \( v_i \) is the velocity of COM of i-th atom-Drude pair or non-polarizable atom. \( v_{M,i} \) is the COM velocity of the molecule the i-th atom-Drude pair or non-polarizable atom belongs to. \( m_i' \) and \( v_i' \) are the reduced mass and the relative velocity of the i-th atom-Drude pair.

Note: These fixes require that each atom knows whether it is a Drude particle or not. You must therefore use the `fix drude` command to specify the Drude status of each atom type.

Because the TGNH thermostat thermostatss the molecular COM motion, all atoms belonging to the same molecule must be in the same group. That is, these fixes can not be applied to a subset of a molecule.

For this fix to act correctly, ghost atoms need to know their velocity. You must use the `comm_modify` command to enable this.

These fixes assume that the translational DOF of the whole system is removed. It is therefore recommended to invoke `fix momentum` command so that the \( T_M \) is calculated correctly.

The thermostat parameters are specified using the `temp` keyword. The thermostat is applied to only the translational DOF for the particles. The translational DOF can also have a bias velocity removed before thermostatting takes place; see the description below. The desired temperature for molecular and real atomic motion is a ramped value during the run from \( T_{start} \) to \( T_{stop} \). The \( T_{damp} \) parameter is specified in time units and determines how rapidly the temperature is relaxed. For example, a value of 10.0 means to relax the temperature in a timespan of (roughly) 10 time units (e.g. \( \tau \) or fs or ps - see the units command). The parameter \( T_{drude} \) is the desired temperature for Drude motion at each timestep. Similar to \( T_{damp} \), the \( T_{damp, drude} \) parameter determines the relaxation speed for Drude motion. Fix group are the only ones whose velocities and positions are updated by the velocity/position update portion of the integration. Other thermostat-related keywords are `tchain` and `tloop`, which are detailed in `fix nvt`.

Note: A Nose-Hoover thermostat will not work well for arbitrary values of \( T_{damp} \). If \( T_{damp} \) is too small, the temperature can fluctuate wildly; if it is too large, the temperature will take a very long time to equilibrate. A good...
choice for many models is a $T_{\text{damp}}$ of around 100 timesteps. A smaller $T_{\text{damp,drude}}$ value would be required to maintain Drude motion at low temperature.

```
fix 1 all nvt temp 300.0 300.0 $(100.0*dt) 1.0 $(20.0*dt)
```

The barostat parameters for fix style tgnpt/drude is specified using one or more of the iso, aniso, tri, x, y, z, xy, xz, yz, and couple keywords. These keywords give you the ability to specify all 6 components of an external stress tensor, and to couple various of these components together so that the dimensions they represent are varied together during a constant-pressure simulation. Other barostat-related keywords are pchain, mtk, ploop, nreset, scalexy, scaleyz, scalexz, flipand fixedpoint. The meaning of barostat parameters are detailed in fix npt.

Regardless of what atoms are in the fix group (the only atoms which are time integrated), a global pressure or stress tensor is computed for all atoms. Similarly, when the size of the simulation box is changed, all atoms are re-scaled to new positions.

**Note:** Unlike the fix temp/berendsen command which performs thermostatting but NO time integration, these fixes perform thermostatting/barostatting AND time integration. Thus you should not use any other time integration fix, such as fix nve on atoms to which this fix is applied. Likewise, these fixes should not be used on atoms that also have their temperature controlled by another fix - e.g. by fix langevin/drude command.

See the Howto thermostat and Howto barostat doc pages for a discussion of different ways to compute temperature and perform thermostatting and barostatting.

Like other fixes that perform thermostatting, this fix can be used with compute commands that remove a “bias” from the atom velocities. E.g. to apply the thermostat only to atoms within a spatial region, or to remove the center-of-mass velocity from a group of atoms, or to remove the x-component of velocity from the calculation.

This is not done by default, but only if the fix_modify command is used to assign a temperature compute to this fix that includes such a bias term. See the doc pages for individual compute temp commands to determine which ones include a bias. In this case, the thermostat works in the following manner: bias is removed from each atom, thermostatting is performed on the remaining thermal degrees of freedom, and the bias is added back in.

**Note:** However, not all temperature compute commands are valid to be used with these fixes. Precisely, only temperature compute that does not modify the DOF of the group can be used. E.g. compute temp/ramp and compute viscosity/cos compute the kinetic energy after remove a velocity gradient without affecting the DOF of the group, then they can be invoked in this way. In contrast, compute temp/partial may remove the DOF at one or more dimensions, therefore it cannot be used with these fixes.

### 17.215.4 Restart, fix_modify, output, run start/stop, minimize info

These fixes writes the state of all the thermostat and barostat variables to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify temp and press options are supported by these fixes. You can use them to assign a compute you have defined to this fix which will be used in its thermostatting or barostatting procedure, as described above. If you do this,
note that the kinetic energy derived from the compute temperature should be consistent with the virial term computed using all atoms for the pressure. LAMMPS will warn you if you choose to compute temperature on a subset of atoms.

**Note:** If both the `temp` and `press` keywords are used in a single thermo_modify command (or in two separate commands), then the order in which the keywords are specified is important. Note that a pressure compute defines its own temperature compute as an argument when it is specified. The `temp` keyword will override this (for the pressure compute being used by fix npt), but only if the `temp` keyword comes after the `press` keyword. If the `temp` keyword comes before the `press` keyword, then the new pressure compute specified by the `press` keyword will be unaffected by the `temp` setting.

The cumulative energy change in the system imposed by these fixes, due to thermostatting and/or barostatting, are included in the `thermodynamic output` keywords `ecouple` and `econserve`. See the `thermo_style` page for details.

These fixes compute a global scalar which can be accessed by various `output commands`. The scalar is the same cumulative energy change due to this fix described in the previous paragraph. The scalar value calculated by this fix is “extensive”.

These fixes also compute a global vector of quantities, which can be accessed by various `output commands`. The vector values are “intensive”. The vector stores the three temperatures $T_M$, $T_R$ and $T_D$.

These fixes can ramp their external temperature and pressure over multiple runs, using the `start` and `stop` keywords of the `run` command. See the `run` command for details of how to do this.

These fixes are not invoked during energy minimization.

### 17.215.5 Restrictions

These fixes are only available when LAMMPS was built with the DRUDE package. These fixes cannot be used with dynamic groups as defined by the `group` command. These fixes cannot be used in 2D simulations.

$X$, $y$, $z$ cannot be barostatted if the associated dimension is not periodic. $Xy$, $xz$, and $yz$ can only be barostatted if the simulation domain is triclinic and the second dimension in the keyword ($y$ dimension in $xy$) is periodic. The `create_box`, `read data`, and `read_restart` commands specify whether the simulation box is orthogonal or non-orthogonal (triclinic) and explain the meaning of the $xy$, $xz$, $yz$ tilt factors.

For the `temp` keyword, the final $T_{stop}$ cannot be 0.0 since it would make the external $T = 0.0$ at some timestep during the simulation which is not allowed in the Nose/Hoover formulation.

The `scaleyz yes`, `scalexz yes`, and `scalexy yes` options can only be used if the second dimension in the keyword is periodic, and if the tilt factor is not coupled to the barostat via keywords $tri$, $yz$, $xz$, and $xy$.

### 17.215.6 Related commands

`fix drude`, `fix nvt`, `fix npt`, `fix modify`
17.215.7 Default

The keyword defaults are tchain = 3, pchain = 3, mtk = yes, tloop = 1, ploop = 1, nreset = 0, couple = none, flip = yes, scaleyz = scalexz = scalexy = yes if periodic in second dimension and not coupled to barostat, otherwise no.

17.216 fix thermal/conductivity command

17.216.1 Syntax

```
fix ID group-ID thermal/conductivity N edim Nbin keyword value ...
```

- ID, group-ID are documented in fix command
- thermal/conductivity = style name of this fix command
- N = perform kinetic energy exchange every N steps
- edim = x or y or z = direction of kinetic energy transfer
- Nbin = # of layers in edim direction (must be even number)
- zero or more keyword/value pairs may be appended
- keyword = swap
  - swap value = Nswap = number of swaps to perform every N steps

17.216.2 Examples

```
fix 1 all thermal/conductivity 100 z 20
fix 1 all thermal/conductivity 50 z 20 swap 2
```

17.216.3 Description

Use the Muller-Plathe algorithm described in this paper to exchange kinetic energy between two particles in different regions of the simulation box every N steps. This induces a temperature gradient in the system. As described below this enables the thermal conductivity of a material to be calculated. This algorithm is sometimes called a reverse non-equilibrium MD (reverse NEMD) approach to computing thermal conductivity. This is because the usual NEMD approach is to impose a temperature gradient on the system and measure the response as the resulting heat flux. In the Muller-Plathe method, the heat flux is imposed, and the temperature gradient is the system’s response.

See the compute heat/flux command for details on how to compute thermal conductivity in an alternate way, via the Green-Kubo formalism.

The simulation box is divided into Nbin layers in the edim direction, where the layer 1 is at the low end of that dimension and the layer Nbin is at the high end. Every N steps, Nswap pairs of atoms are chosen in the following manner. Only atoms in the fix group are considered. The hottest Nswap atoms in layer 1 are selected. Similarly, the coldest Nswap atoms in the “middle” layer (see below) are selected. The two sets of Nswap atoms are paired up and their velocities are exchanged. This effectively swaps their kinetic energies, assuming their masses are the same. If the masses are different, an exchange of velocities relative to center of mass motion of the 2 atoms is performed, to conserve kinetic energy.
energy. Over time, this induces a temperature gradient in the system which can be measured using commands such as
the following, which writes the temperature profile (assuming z = edim) to the file tmp.profile:

```
compute      ke all ke/atom
variable     temp atom c_ke/1.5
compute      layers all chunk/atom bin/1d z lower 0.05 units reduced
fix          3 all ave/chunk 10 100 1000 layers v_temp file tmp.profile
```

Note that by default, Nswap = 1, though this can be changed by the optional swap keyword. Setting this parameter
appropriately, in conjunction with the swap rate N, allows the heat flux to be adjusted across a wide range of values,
and the kinetic energy to be exchanged in large chunks or more smoothly.

The “middle” layer for velocity swapping is defined as the \( Nbin/2 + 1 \) layer. Thus if \( Nbin = 20 \), the two swapping
layers are 1 and 11. This should lead to a symmetric temperature profile since the two layers are separated by the same
distance in both directions in a periodic sense. This is why \( Nbin \) is restricted to being an even number.

As described below, the total kinetic energy transferred by these swaps is computed by the fix and can be output.
Dividing this quantity by time and the cross-sectional area of the simulation box yields a heat flux. The ratio of heat
flux to the slope of the temperature profile is proportional to the thermal conductivity of the fluid, in appropriate units.
See the Muller-Plathe paper for details.

**Note:** If your system is periodic in the direction of the heat flux, then the flux is going in 2 directions. This means the
effective heat flux in one direction is reduced by a factor of 2. You will see this in the equations for thermal conductivity
(kappa) in the Muller-Plathe paper. LAMMPS is simply tallying kinetic energy which does not account for whether or
not your system is periodic; you must use the value appropriately to yield a kappa for your system.

**Note:** After equilibration, if the temperature gradient you observe is not linear, then you are likely swapping energy
too frequently and are not in a regime of linear response. In this case you cannot accurately infer a thermal conductivity
and should try increasing the Nevery parameter.

### 17.216.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the cumulative
kinetic energy transferred between the bottom and middle of the simulation box (in the edim direction) is stored as a
scalar quantity by this fix. This quantity is zeroed when the fix is defined and accumulates thereafter, once every N
steps. The units of the quantity are energy; see the units command for details. The scalar value calculated by this fix is
“intensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during
energy minimization.
17.216.5 Restrictions

Swaps conserve both momentum and kinetic energy, even if the masses of the swapped atoms are not equal. Thus you should not need to thermostat the system. If you do use a thermostat, you may want to apply it only to the non-swapped dimensions (other than $vdim$).

LAMMPS does not check, but you should not use this fix to swap the kinetic energy of atoms that are in constrained molecules, e.g. via `fix shake` or `fix rigid`. This is because application of the constraints will alter the amount of transferred momentum. You should, however, be able to use flexible molecules. See the Zhang paper for a discussion and results of this idea.

When running a simulation with large, massive particles or molecules in a background solvent, you may want to only exchange kinetic energy between solvent particles.

17.216.6 Related commands

`fix ehex`, `fix heat`, `fix ave/chunk`, `fix viscosity`, `compute heat/flux`

17.216.7 Default

The option defaults are swap = 1.

---

17.217 fix ti/spring command

17.217.1 Syntax

```
fix ID group-ID ti/spring k t_s t_eq keyword value ...
```

- ID, group-ID are documented in `fix` command
- ti/spring = style name of this fix command
- k = spring constant (force/distance units)
- t_eq = number of steps for the equilibration procedure
- t_s = number of steps for the switching procedure
- zero or more keyword/value pairs may be appended to args
- keyword = `function`
  ```
  function value = function-ID
  function-ID = ID of the switching function (1 or 2)
  ```
17.217.2 Example

```
fix 1 all ti/spring 50.0 2000 1000 function 2
```

17.217.3 Description

This fix allows you to compute the free energy of crystalline solids by performing a nonequilibrium thermodynamic integration between the solid of interest and an Einstein crystal. A detailed explanation of how to use this command and choose its parameters for optimal performance and accuracy is given in the paper by Freitas. The paper also presents a short summary of the theory of nonequilibrium thermodynamic integration.

The thermodynamic integration procedure is performed by rescaling the force on each atom. Given an atomic configuration the force (F) on each atom is given by

\[ F = (1 - \lambda) F_{\text{solid}} + \lambda F_{\text{harm}} \]

where \( F_{\text{solid}} \) is the force that acts on an atom due to an interatomic potential (e.g. EAM potential), \( F_{\text{harm}} \) is the force due to the Einstein crystal harmonic spring, and \( \lambda \) is the coupling parameter of the thermodynamic integration. An Einstein crystal is a solid where each atom is attached to its equilibrium position by a harmonic spring with spring constant \( k \). With this fix a spring force is applied independently to each atom in the group defined by the fix to tether it to its initial position. The initial position of each atom is its position at the time the fix command was issued.

The fix acts as follows: during the first \( t_{eq} \) steps after the fix is defined the value of \( \lambda \) is zero. This is the period to equilibrate the system in the \( \lambda = 0 \) state. After this the value of \( \lambda \) changes dynamically during the simulation from 0 to 1 according to the function defined using the keyword `function` (described below), this switching from \( \lambda = 0 \) to \( \lambda = 1 \) is done in \( t_s \) steps. Then comes the second equilibration period of \( t_{eq} \) to equilibrate the system in the \( \lambda = 1 \) state. After that, the switching back to the \( \lambda = 0 \) state is made using \( t_s \) timesteps and following the same switching function. After this period the value of \( \lambda \) is kept equal to zero and the fix has no other effect on the dynamics of the system.

The processes described above is known as nonequilibrium thermodynamic integration and is has been shown (Freitas) to present a much superior efficiency when compared to standard equilibrium methods. The reason why the switching it is made in both directions (potential to Einstein crystal and back) is to eliminate the dissipated heat due to the nonequilibrium process. Further details about nonequilibrium thermodynamic integration and its implementation in LAMMPS is available in Freitas.

The `function` keyword allows the use of two different \( \lambda \) paths. Option 1 results in a constant rate of change of \( \lambda \) with time:

\[ \lambda(\tau) = \tau \]

where \( \tau \) is the scaled time variable \( t/t_s \). The option 2 performs the lambda switching at a rate defined by the following switching function

\[ \lambda(\tau) = \tau^5 (70\tau^4 - 315\tau^3 + 540\tau^2 - 420\tau + 126) \]

This function has zero slope as \( \lambda \) approaches its extreme values (0 and 1), according to de Koning this results in smaller fluctuations on the integral to be computed on the thermodynamic integration. The use of option 2 is recommended since it results in better accuracy and less dissipation without any increase in computational resources cost.

Note: As described in Freitas, it is important to keep the center-of-mass fixed during the thermodynamic integration. A nonzero total velocity will result in divergences during the integration due to the fact that the atoms are ‘attached’ to their equilibrium positions by the Einstein crystal. Check the option `zero of fix langevin` and `velocity`. The use of the
Nose-Hoover thermostat (fix nvt) is NOT recommended due to its well documented issues with the canonical sampling of harmonic degrees of freedom (notice that the chain option will NOT solve this problem). The Langevin thermostat (fix langevin) correctly thermostats the system and we advise its usage with ti/spring command.

17.217.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the original coordinates of tethered atoms to binary restart files, so that the spring effect will be the same in a restarted simulation. See the read restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

The fix_modify energy option is supported by this fix to add the energy stored in the per-atom springs to the global potential energy of the system as part of thermodynamic output. The default setting for this fix is fix_modify energy no.

This fix computes a global scalar and a global vector quantities which can be accessed by various output commands. The scalar is an energy which is the sum of the spring energy for each atom, where the per-atom energy is \(0.5 \cdot k \cdot r^2\). The vector stores 2 values. The first value is the coupling parameter lambda. The second value is the derivative of lambda with respect to the integer timestep \(s\), i.e. \(\frac{d\lambda}{ds}\). In order to obtain \(\frac{d\lambda}{dt}\), where \(t\) is simulation time, this 2nd value needs to be divided by the timestep size (e.g. 0.5 fs). The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command.

**Note:** If you want the per-atom spring energy to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the fix_modify energy option for this fix.

17.217.5 Related commands

fix spring, fix adapt

17.217.6 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

17.217.7 Default

The keyword default is function = 1.

17.218 fix tmd command

17.218.1 Syntax

<table>
<thead>
<tr>
<th>Fix ID</th>
<th>Group-ID</th>
<th>TMD</th>
<th>Rho Final</th>
<th>File1</th>
<th>N</th>
<th>File2</th>
</tr>
</thead>
<tbody>
<tr>
<td>fix</td>
<td>group-ID</td>
<td>tmd</td>
<td>rho_final</td>
<td>file1</td>
<td>N</td>
<td>file2</td>
</tr>
</tbody>
</table>

- ID, group-ID are documented in fix command
- tmd = style name of this fix command
- rho_final = desired value of rho at the end of the run (distance units)
- file1 = filename to read target structure from
- N = dump TMD statistics every this many timesteps, 0 = no dump
- file2 = filename to write TMD statistics to (only needed if N > 0)

17.218.2 Examples

```
fix 1 all nve
fix 2 tmdatoms tmd 1.0 target_file 100 tmd_dump_file
```

17.218.3 Description

Perform targeted molecular dynamics (TMD) on a group of atoms. A holonomic constraint is used to force the atoms to move towards (or away from) the target configuration. The parameter “rho” is monotonically decreased (or increased) from its initial value to rho_final at the end of the run.

Rho has distance units and is a measure of the root-mean-squared distance (RMSD) between the current configuration of the atoms in the group and the target coordinates listed in file1. Thus a value of rho_final = 0.0 means move the atoms all the way to the final structure during the course of the run.

The target file1 can be ASCII text or a gzipped text file (detected by a .gz suffix). The format of the target file1 is as follows:

```
0.0 25.0 xlo xhi
0.0 25.0 ylo yhi
0.0 25.0 zlo zhi
125 24.97311 1.69005 23.46956 0 0 -1

...
```

The first 3 lines may or may not be needed, depending on the format of the atoms to follow. If image flags are included with the atoms, the first 3 lo/hi lines must appear in the file. If image flags are not included, the first 3 lines must not appear. The 3 lines contain the simulation box dimensions for the atom coordinates, in the same format as in a LAMMPS data file (see the read_data command).

The remaining lines each contain an atom ID and its target x,y,z coordinates. The atom lines (all or none of them) can optionally be followed by 3 integer values: nx,ny,nz. For periodic dimensions, they specify which image of the box the atom is considered to be in, i.e. a value of N (positive or negative) means add N times the box length to the coordinate to get the true value. Those 3 integers either must be given for all atoms or none.
The atom lines can be listed in any order, but every atom in the group must be listed in the file. Atoms not in the fix group may also be listed; they will be ignored.

Comments starting with ‘#’ and empty lines may be included as well.

TMD statistics are written to file2 every N timesteps, unless N is specified as 0, which means no statistics.

The atoms in the fix tmd group should be integrated (via a fix nve, nvt, npt) along with other atoms in the system.

Restarts can be used with a fix tmd command. For example, imagine a 10000 timestep run with a rho_initial = 11 and a rho_final = 1. If a restart file was written after 2000 time steps, then the configuration in the file would have a rho value of 9. A new 8000 time step run could be performed with the same rho_final = 1 to complete the conformational change at the same transition rate. Note that for restarted runs, the name of the TMD statistics file should be changed to prevent it being overwritten.

For more information about TMD, see (Schlitter1) and (Schlitter2).

### 17.218.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands.

This fix can ramp its rho parameter over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.

This fix is not invoked during energy minimization.

### 17.218.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

All TMD fixes must be listed in the input script after all integrator fixes (nve, nvt, npt) are applied. This ensures that atoms are moved before their positions are corrected to comply with the constraint.

Atoms that have a TMD fix applied should not be part of a group to which a SHAKE fix is applied. This is because LAMMPS assumes there are not multiple competing holonomic constraints applied to the same atoms.

To read gzipped target files, you must compile LAMMPS with the -DLAMMPS_GZIP option. See the Build settings doc page for details.

17.221.3 Description

Use a two-temperature model (TTM) to represent heat transfer through and between electronic and atomic subsystems. LAMMPS models the atomic subsystem as usual with a molecular dynamics model and the classical force field specified by the user. The electronic subsystem is modeled as a continuum, or a background “gas”, on a regular grid which overlays the simulation domain. Energy can be transferred spatially within the grid representing the electrons. Energy can also be transferred between the electronic and atomic subsystems. The algorithm underlying this fix was derived by D. M. Duffy and A. M. Rutherford and is discussed in two J Physics: Condensed Matter papers: (Duffy) and (Rutherford). They used this algorithm in cascade simulations where a primary knock-on atom (PKA) was initialized with a high velocity to simulate a radiation event.

The description in this sub-section applies to all 3 fix styles: ttm, ttm/grid, and ttm/mod.

Fix ttm/grid distributes the regular grid across processors consistent with the sub-domains of atoms owned by each processor, but is otherwise identical to fix ttm. Note that fix ttm stores a copy of the grid on each processor, which is acceptable when the overall grid is reasonably small. For larger grids you should use fix ttm/grid instead.

Fix ttm/mod adds options to account for external heat sources (e.g. at a surface) and for specifying parameters that allow the electronic heat capacity to depend strongly on electronic temperature. It is more expensive computationally than fix ttm because it treats the thermal diffusion equation as non-linear. More details on fix ttm/mod are given below.

Heat transfer between the electronic and atomic subsystems is carried out via an inhomogeneous Langevin thermostat. Only atoms in the fix group contribute to and are affected by this heat transfer.

This thermostating differs from the regular Langevin thermostat (fix langevin) in three important ways. First, the Langevin thermostat is applied uniformly to all atoms in the user-specified group for a single target temperature, whereas the TTM fixes apply Langevin thermostating locally to atoms within the volumes represented by the user-specified grid points with a target temperature specific to that grid point. Second, the Langevin thermostat couples the temperature of the atoms to an infinite heat reservoir, whereas the heat reservoir for the TTM fixes is finite and represents the local electrons. Third, the TTM fixes allow users to specify not just one friction coefficient, but rather two independent friction coefficients: one for the electron-ion interactions (gamma_p), and one for electron stopping (gamma_s).

When the friction coefficient due to electron stopping, gamma_s, is non-zero, electron stopping effects are included for atoms moving faster than the electron stopping critical velocity, v_0. For further details about this algorithm, see (Duffy) and (Rutherford).

Energy transport within the electronic subsystem is solved according to the heat diffusion equation with added source terms for heat transfer between the subsystems:

\[ C_e \rho_e \frac{\partial T_e}{\partial t} = \nabla (\kappa_e \nabla T_e) - g_p (T_e - T_a) + g_s T_a' \]

where \( C_e \) is the specific heat, \( \rho_e \) is the density, \( \kappa_e \) is the thermal conductivity, \( T \) is temperature, the “e” and “a” subscripts represent electronic and atomic subsystems respectively, \( g_p \) is the coupling constant for the electron-ion interaction, and \( g_s \) is the electron stopping coupling parameter. \( C_e, \rho_e, \) and \( \kappa_e \) are specified as parameters to the fix. The other quantities are derived. The form of the heat diffusion equation used here is almost the same as that in equation 6 of (Duffy), with the exception that the electronic density is explicitly represented, rather than being part of the specific heat parameter.
Currently, the TTM fixes assume that none of the user-supplied parameters will vary with temperature. Note that (Duffy) used a tanh() functional form for the temperature dependence of the electronic specific heat, but ignored temperature dependencies of any of the other parameters. See more discussion below for fix ttm/mod.

**Note:** These fixes do not perform time integration of the atoms in the fix group, they only rescale their velocities. Thus a time integration fix such as fix nve should be used in conjunction with these fixes. These fixes should not normally be used on atoms that have their temperature controlled by another thermostating fix, e.g. fix nvt or fix langevin.

**Note:** These fixes require use of an orthogonal 3d simulation box with periodic boundary conditions in all dimensions. They also require that the size and shape of the simulation box do not vary dynamically, e.g. due to use of the fix npt command. Likewise, the size/shape of processor sub-domains cannot vary due to dynamic load-balancing via use of the fix balance command. It is possible however to load balance before the simulation starts using the balance command, so that each processor has a different size sub-domain.

Periodic boundary conditions are also used in the heat equation solve for the electronic subsystem. This varies from the approach of (Rutherford) where the atomic subsystem was embedded within a larger continuum representation of the electronic subsystem.

The *set* keyword specifies a $T_{\text{init}}$ temperature value to initialize the value stored on all grid points.

The *infile* keyword specifies an input file of electronic temperatures for each grid point to be read in to initialize the grid. By default the temperatures are all zero when the grid is created. The input file is a text file which may have comments starting with the ‘#’ character. Each line contains four numeric columns: $ix, iy, iz, \text{Temperature}$. Empty or comment-only lines will be ignored. The number of lines must be equal to the number of user-specified grid points $(Nx \times Ny \times Nz)$. The $ix, iy, iz$ are grid point indices ranging from 0 to $nxnodes-1$ inclusive in each dimension. The lines can appear in any order. For example, the initial electronic temperatures on a 1 by 2 by 3 grid could be specified in the file as follows:

```
# UNITS: metal COMMENT: initial electron temperature
0 0 0 1.0
0 0 1 1.0
0 0 2 1.0
0 1 0 2.0
0 1 1 2.0
0 1 2 2.0
```

where the electronic temperatures along the $y=0$ plane have been set to 1.0, and the electronic temperatures along the $y=1$ plane have been set to 2.0. If all the grid point values are not specified, LAMMPS will generate an error. LAMMPS will check if a “UNITS:” tag is in the first line and stop with an error, if there is a mismatch with the current units used.

**Note:** The electronic temperature at each grid point must be a non-zero positive value, both initially, and as the temperature evolves over time. Thus you must use either the *set* or *infile* keyword or be restarting a simulation that used this fix previously.

The *outfile* keyword has 2 values. The first value $N_{\text{out}}$ triggers output of the electronic temperatures for each grid point every $N_{\text{out}}$ timesteps. The second value is the filename for output which will be suffixed by the timestep. The format of each output file is exactly the same as the input temperature file. It will contain a comment in the first line reporting the date the file was created, the LAMMPS units setting in use, grid size and the current timestep.

Note that the atomic temperature for atoms in each grid cell can also be computed and output by the fix ave/chunk command using the *compute chunk/atom* command to create a 3d array of chunks consistent with the grid used by this fix.
Additional details for fix ttm/mod

Fix ttm/mod uses the heat diffusion equation with possible external heat sources (e.g. laser heating in ablation simulations):

\[ C_e \rho_e \frac{\partial T_e}{\partial t} = \nabla(\kappa_e \nabla T_e) - g_p(T_e - T_a) + g_s T'_a + \theta (x - x_{\text{surface}}) I_0 \exp(-x/l_{\text{skin}}) \]

where theta is the Heaviside step function, I_0 is the (absorbed) laser pulse intensity for ablation simulations, l_skin is the depth of skin-layer, and all other designations have the same meaning as in the former equation. The duration of the pulse is set by the parameter tau in the init_file.

Fix ttm/mod also allows users to specify the dependencies of C_e and kappa_e on the electronic temperature. The specific heat is expressed as

\[ C_e = C_0 + (a_0 + a_1 X + a_2 X^2 + a_3 X^3 + a_4 X^4) \exp(-(AX)^2) \]

where \( X = T_e/1000 \), and the thermal conductivity is defined as \( \kappa_e = D_e \rho_e C_e \), where \( D_e \) is the thermal diffusion coefficient.

Electronic pressure effects are included in the TTM model to account for the blast force acting on ions because of electronic pressure gradient (see (Chen), (Norman)). The total force acting on an ion is:

\[ \vec{F}_i = -\nabla U/\partial \vec{r}_i + \vec{F}_{\text{langevin}} - \nabla P_e/n_{\text{ion}} \]

where \( F_{\text{langevin}} \) is a force from Langevin thermostat simulating electron-phonon coupling, and \( \nabla P_e/n_{\text{ion}} \) is the electron blast force.

The electronic pressure is taken to be \( P_e = B\rho_e C_e T_e \)

The current fix ttm/mod implementation allows TTM simulations with a vacuum. The vacuum region is defined as the grid cells with zero electronic temperature. The numerical scheme does not allow energy exchange with such cells. Since the material can expand to previously unoccupied region in some simulations, the vacuum border can be allowed to move. It is controlled by the surface_movement parameter in the init_file. If it is set to 1, then “vacuum” cells can be changed to “electron-filled” cells with the temperature \( T_{e_{\text{min}}} \) if atoms move into them (currently only implemented for the case of 1-dimensional motion of flat surface normal to the X axis). The initial borders of vacuum can be set in the init_file via lsurface and rsurface parameters. In this case, electronic pressure gradient is calculated as:

\[ \nabla x P_e = \left[ \frac{C_e T_e(x)\lambda}{(x + \lambda)^2} + \frac{x}{x + \lambda} \frac{(C_e T_e)_{x+\Delta x} - (C_e T_e)_{x}}{\Delta x} \right] \]

where lambda is the electron mean free path (see (Norman), (Pisarev)).

The fix ttm/mod parameter file init_file has the following syntax. Every line with an odd number is considered as a comment and ignored. The lines with the even numbers are treated as follows:

- \( a_0 \), energy/(temperature*electron) units
- \( a_1 \), energy/(temperature^2*electron) units
- \( a_2 \), energy/(temperature^3*electron) units
- \( a_3 \), energy/(temperature^4*electron) units
- \( a_4 \), energy/(temperature^5*electron) units
- \( C_0 \), energy/(temperature*electron) units
- \( A \), 1/temperature units
- \( \rho_e \), electrons/volume units
- \( D_e \), length^2/time units
- \( \gamma_p \), mass/time units
- \( \gamma_s \), mass/time units
v_0, length/time units
I_0, energy/(time*length^2) units
lsurface, electron grid units (positive integer)
rsurface, electron grid units (positive integer)
l_skin, length units
tau, time units
B, dimensionless
lambda, length units
n_ion, ions/volume units
surface_movement: 0 to disable tracking of surface motion, 1 to enable
T_e_min, temperature units

17.221.4 Restart, fix_modify, output, run start/stop, minimize info

These fixes write the state of the electronic subsystem and the energy exchange between the subsystems to binary restart files. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion. Note that the restart script must define the same size grid as the original script.

Because the state of the random number generator is not saved in the restart files, this means you cannot do “exact” restarts with this fix, where the simulation continues on the same as if no restart had taken place. However, in a statistical sense, a restarted simulation should produce the same behavior.

None of the fix_modify options are relevant to these fixes.

These fixes compute 2 output quantities stored in a vector of length 2, which can be accessed by various output commands. The first quantity is the total energy of the electronic subsystem. The second quantity is the energy transferred from the electronic to the atomic subsystem on that timestep. Note that the velocity verlet integrator applies the fix ttm forces to the atomic subsystem as two half-step velocity updates: one on the current timestep and one on the subsequent timestep. Consequently, the change in the atomic subsystem energy is lagged by half a timestep relative to the change in the electronic subsystem energy. As a result of this, users may notice slight fluctuations in the sum of the atomic and electronic subsystem energies reported at the end of the timestep.

The vector values calculated are “extensive”.

No parameter of the fixes can be used with the start/stop keywords of the run command. The fixes are not invoked during energy minimization.

17.221.5 Restrictions

All these fixes are part of the EXTRA-FIX package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

As mentioned above, these fixes require 3d simulations and orthogonal simulation boxes periodic in all 3 dimensions.

```

- ID, group-ID are documented in *fix* command
- tune/kspace = style name of this fix command
- N = invoke this fix every N steps

17.222.2 Examples

```markdown
fix 2 all tune/kspace 100
```

17.222.3 Description

This fix tests each kspace style (Ewald, PPPM, and MSM), and automatically selects the fastest style to use for the remainder of the run. If the fastest style is Ewald or PPPM, the fix also adjusts the Coulombic cutoff towards optimal speed. Future versions of this fix will automatically select other kspace parameters to use for maximum simulation speed. The kspace parameters may include the style, cutoff, grid points in each direction, order, Ewald parameter, MSM parallelization cut-point, MPI tasks to use, etc.

The rationale for this fix is to provide the user with as-fast-as-possible simulations that include long-range electrostatics (kspace) while meeting the user-prescribed accuracy requirement. A simple heuristic could never capture the optimal combination of parameters for every possible run-time scenario. But by performing short tests of various kspace parameter sets, this fix allows parameters to be tailored specifically to the user’s machine, MPI ranks, use of threading or accelerators, the simulated system, and the simulation details. In addition, it is possible that parameters could be evolved with the simulation on-the-fly, which is useful for systems that are dynamically evolving (e.g. changes in box size/shape or number of particles).
When this fix is invoked, LAMMPS will perform short timed tests of various parameter sets to determine the optimal parameters. Tests are performed on-the-fly, with a new test initialized every N steps. N should be chosen large enough so that adequate CPU time lapses between tests, thereby providing statistically significant timings. But N should not be chosen to be so large that an unfortunate parameter set test takes an inordinate amount of wall time to complete. An N of 100 for most problems seems reasonable. Once an optimal parameter set is found, that set is used for the remainder of the run.

This fix uses heuristics to guide it’s selection of parameter sets to test, but the actual timed results will be used to decide which set to use in the simulation.

It is not necessary to discard trajectories produced using sub-optimal parameter sets, or a mix of various parameter sets, since the user-prescribed accuracy will have been maintained throughout. However, some users may prefer to use this fix only to discover the optimal parameter set for a given setup that can then be used on subsequent production runs.

This fix starts with kspace parameters that are set by the user with the \texttt{kspace\_style} and \texttt{kspace\_modify} commands. The prescribed accuracy will be maintained by this fix throughout the simulation.

None of the \texttt{fix\_modify} options are relevant to this fix.

No parameter of this fix can be used with the \texttt{start/stop} keywords of the \texttt{run} command. This fix is not invoked during energy minimization.

\section*{17.222.4 Restrictions}

This fix is part of the KSPACE package. It is only enabled if LAMMPS was built with that package. See the \texttt{Build package} page for more info.

Do not set “neigh\_modify once yes” or else this fix will never be called. Reneighboring is required.

This fix is not compatible with a hybrid pair style, long-range dispersion, TIP4P water support, or long-range point dipole support.

\[ c_{\text{ID}}[I] = \text{Ith component of global vector calculated by a compute with ID} \]
\[ f_{\text{ID}} = \text{global scalar calculated by a fix with ID} \]
\[ f_{\text{ID}[I]} = \text{Ith component of global vector calculated by a fix with ID} \]
v_name = value calculated by an equal-style variable with name
\[ v_{\text{name}[I]} = \text{Ith component of vector-style variable with name} \]

17.223.2 Examples

```bash
fix 1 all vector 100 c_myTemp
fix 1 all vector 5 c_myTemp v_integral
```

17.223.3 Description

Use one or more global values as inputs every few timesteps, and simply store them. For a single specified value, the values are stored as a global vector of growing length. For multiple specified values, they are stored as rows in a global array, whose number of rows is growing. The resulting vector or array can be used by other output commands.

One way to use this command is to accumulate a vector that is time-integrated using the variable trap() function. For example, the velocity auto-correlation function (VACF) can be time-integrated, to yield a diffusion coefficient, as follows:

```bash
compute 2 all vacf
fix 5 all vector 1 c_2[4]
variable diff equal dt*trap(f_5)
thermo_style custom step v_diff
```

The group specified with this command is ignored. However, note that specified values may represent calculations performed by computes and fixes which store their own “group” definitions.

Each listed value can be the result of a compute or fix or the evaluation of an equal-style or vector-style variable. In each case, the compute, fix, or variable must produce a global quantity, not a per-atom or local quantity. And the global quantity must be a scalar, not a vector or array.

Computes that produce global quantities are those which do not have the word atom in their style name. Only a few fixes produce global quantities. See the doc pages for individual fixes for info on which ones produce such values. Variables of style equal or vector are the only ones that can be used with this fix. Variables of style atom cannot be used, since they produce per-atom values.

The Nevery argument specifies on what timesteps the input values will be used in order to be stored. Only timesteps that are a multiple of Nevery, including timestep 0, will contribute values.

Note that if you perform multiple runs, using the “pre no” option of the run command to avoid initialization on subsequent runs, then you need to use the stop keyword with the first run command with a timestep value that encompasses all the runs. This is so that the vector or array stored by this fix can be allocated to a sufficient size.

If a value begins with “c_”, a compute ID must follow which has been previously defined in the input script. If no bracketed term is appended, the global scalar calculated by the compute is used. If a bracketed term is appended, the Ith element of the global vector calculated by the compute is used.

Note that there is a compute reduce command which can sum per-atom quantities into a global scalar or vector which can thus be accessed by fix vector. Or it can be a compute defined not in your input script, but by thermodynamic output.
or other fixes such as *fix nvt* or *fix temp/rescale*. See the doc pages for these commands which give the IDs of these computes. Users can also write code for their own compute styles and *add them to LAMMPS*.

If a value begins with “f_”, a fix ID must follow which has been previously defined in the input script. If no bracketed term is appended, the global scalar calculated by the fix is used. If a bracketed term is appended, the Ith element of the global vector calculated by the fix is used.

Note that some fixes only produce their values on certain timesteps, which must be compatible with *Nevery*, else an error will result. Users can also write code for their own fix styles and *add them to LAMMPS*.

If a value begins with “v_”, a variable name must follow which has been previously defined in the input script. An equal-style or vector-style variable can be referenced; the latter requires a bracketed term to specify the Ith element of the vector calculated by the variable. See the *variable* command for details. Note that variables of style *equal* and *vector* define a formula which can reference individual atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of specifying quantities to be stored by fix vector.

---

### 17.223.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix_modify* options are relevant to this fix.

This fix produces a global vector or global array which can be accessed by various *output commands*. The values can only be accessed on timesteps that are multiples of *Nevery*.

A vector is produced if only a single input value is specified. An array is produced if multiple input values are specified. The length of the vector or the number of rows in the array grows by 1 every *Nevery* timesteps.

If the fix produces a vector, then the entire vector will be either “intensive” or “extensive”, depending on whether the values stored in the vector are “intensive” or “extensive”. If the fix produces an array, then all elements in the array must be the same, either “intensive” or “extensive”. If a compute or fix provides the value stored, then the compute or fix determines whether the value is intensive or extensive; see the page for that compute or fix for further info. Values produced by a variable are treated as intensive.

This fix can allocate storage for stored values accumulated over multiple runs, using the *start* and *stop* keywords of the *run* command. See the *run* command for details of how to do this. If using the *run pre no* command option, this is required to allow the fix to allocate sufficient storage for stored values.

This fix is not invoked during *energy minimization*.

17.224.3 Description

Use the Muller-Plathe algorithm described in this paper to exchange momenta between two particles in different regions of the simulation box every N steps. This induces a shear velocity profile in the system. As described below this enables a viscosity of the fluid to be calculated. This algorithm is sometimes called a reverse non-equilibrium MD (reverse NEMD) approach to computing viscosity. This is because the usual NEMD approach is to impose a shear velocity profile on the system and measure the response via an off-diagonal component of the stress tensor, which is proportional to the momentum flux. In the Muller-Plathe method, the momentum flux is imposed, and the shear velocity profile is the system’s response.

The simulation box is divided into Nbin layers in the pdim direction, where the layer 1 is at the low end of that dimension and the layer Nbin is at the high end. Every N steps, Nswap pairs of atoms are chosen in the following manner. Only atoms in the fix group are considered. Nswap atoms in layer 1 with positive velocity components in the vdim direction closest to the target value V are selected. Similarly, Nswap atoms in the “middle” layer (see below) with negative velocity components in the vdim direction closest to the negative of the target value V are selected. The two sets of Nswap atoms are paired up and their vdim momenta components are swapped within each pair. This resets their velocities, typically in opposite directions. Over time, this induces a shear velocity profile in the system which can be measured using commands such as the following, which writes the profile to the file tmp.profile:
compute layers all chunk/atom bin/1d z lower 0.05 units reduced
fix f1 all ave/chunk 100 10 1000 layers vx file tmp.profile

Note that by default, Nswap = 1 and vtarget = INF, though this can be changed by the optional swap and vtarget keywords. When vtarget = INF, one or more atoms with the most positive and negative velocity components are selected. Setting these parameters appropriately, in conjunction with the swap rate N, allows the momentum flux rate to be adjusted across a wide range of values, and the momenta to be exchanged in large chunks or more smoothly.

The “middle” layer for momenta swapping is defined as the Nbin/2 + 1 layer. Thus if Nbin = 20, the two swapping layers are 1 and 11. This should lead to a symmetric velocity profile since the two layers are separated by the same distance in both directions in a periodic sense. This is why Nbin is restricted to being an even number.

As described below, the total momentum transferred by these velocity swaps is computed by the fix and can be output. Dividing this quantity by time and the cross-sectional area of the simulation box yields a momentum flux. The ratio of momentum flux to the slope of the shear velocity profile is proportional to the viscosity of the fluid, in appropriate units. See the Muller-Plathe paper for details.

Note: If your system is periodic in the direction of the momentum flux, then the flux is going in 2 directions. This means the effective momentum flux in one direction is reduced by a factor of 2. You will see this in the equations for viscosity in the Muller-Plathe paper. LAMMPS is simply tallying momentum which does not account for whether or not your system is periodic; you must use the value appropriately to yield a viscosity for your system.

Note: After equilibration, if the velocity profile you observe is not linear, then you are likely swapping momentum too frequently and are not in a regime of linear response. In this case you cannot accurately infer a viscosity and should try increasing the Nevery parameter.

An alternative method for calculating a viscosity is to run a NEMD simulation, as described on the Howto nemd doc page. NEMD simulations deform the simulation box via the fix deform command.

Some features or combination of settings in LAMMPS do not support non-orthogonal boxes. Using fix viscosity keeps the box orthogonal; thus it does not suffer from these limitations.

17.224.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix.

This fix computes a global scalar which can be accessed by various output commands. The scalar is the cumulative momentum transferred between the bottom and middle of the simulation box (in the pdim direction) is stored as a scalar quantity by this fix. This quantity is zeroed when the fix is defined and accumulates thereafter, once every N steps. The units of the quantity are momentum = mass*velocity. The scalar value calculated by this fix is “intensive”.

No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.
17.224.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

Swaps conserve both momentum and kinetic energy, even if the masses of the swapped atoms are not equal. Thus you should not need to thermostat the system. If you do use a thermostat, you may want to apply it only to the non-swapped dimensions (other than vdim).

LAMMPS does not check, but you should not use this fix to swap velocities of atoms that are in constrained molecules, e.g. via fix shake or fix rigid. This is because application of the constraints will alter the amount of transferred momentum. You should, however, be able to use flexible molecules. See the Maginn paper for an example of using this algorithm in a computation of alcohol molecule properties.

When running a simulation with large, massive particles or molecules in a background solvent, you may want to only exchange momenta between solvent particles.

fix ID group-ID viscous gamma keyword values ...

- ID, group-ID are documented in fix command
- viscous = style name of this fix command
- gamma = damping coefficient (force/velocity units)
- zero or more keyword/value pairs may be appended
  keyword = scale
  scale values = type ratio
  type = atom type (1-N)
  ratio = factor to scale the damping coefficient by
17.225.2 Examples

```
fix 1 flow viscous 0.1
fix 1 damp viscous 0.5 scale 3 2.5
```

17.225.3 Description

Add a viscous damping force to atoms in the group that is proportional to the velocity of the atom. The added force can be thought of as a frictional interaction with implicit solvent, i.e. the no-slip Stokes drag on a spherical particle. In granular simulations this can be useful for draining the kinetic energy from the system in a controlled fashion. If used without additional thermostatting (to add kinetic energy to the system), it has the effect of slowly (or rapidly) freezing the system; hence it can also be used as a simple energy minimization technique.

The damping force \( F_i \) is given by \( F_i = -\gamma v_i \). The larger the coefficient, the faster the kinetic energy is reduced. If the optional keyword `scale` is used, \( \gamma \) can scaled up or down by the specified factor for atoms of that type. It can be used multiple times to adjust \( \gamma \) for several atom types.

**Note:** You should specify gamma in force/velocity units. This is not the same as mass/time units, at least for some of the LAMMPS units options like “real” or “metal” that are not self-consistent.

In a Brownian dynamics context, \( \gamma = \frac{k_B T}{D} \), where \( k_B \) = Boltzmann’s constant, \( T \) = temperature, and \( D \) = particle diffusion coefficient. \( D \) can be written as \( \frac{k_B T}{3\pi \eta d} \), where \( \eta \) = dynamic viscosity of the frictional fluid and \( d \) = diameter of particle. This means \( \gamma = 3\pi \eta d \), and thus is proportional to the viscosity of the fluid and the particle diameter.

In the current implementation, rather than have the user specify a viscosity, \( \gamma \) is specified directly in force/velocity units. If needed, \( \gamma \) can be adjusted for atoms of different sizes (i.e. \( \sigma \)) by using the `scale` keyword.

Note that Brownian dynamics models also typically include a randomized force term to thermostat the system at a chosen temperature. The `fix langevin` command does this. It has the same viscous damping term as fix viscous and adds a random force to each atom. The random force term is proportional to the square root of the chosen thermostatting temperature. Thus if you use fix langevin with a target \( T = 0 \), its random force term is zero, and you are essentially performing the same operation as fix viscous. Also note that the gamma of fix viscous is related to the damping parameter of `fix langevin`, however the former is specified in units of force/velocity and the latter in units of time, so that it can more easily be used as a thermostat.

17.225.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the `fix_modify` options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the `start/stop` keywords of the `run` command.

The `fix_modify respa` option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is modifying forces. Default is the outermost level.

The forces due to this fix are imposed during an energy minimization, invoked by the `minimize` command. This fix should only be used with damped dynamics minimizers that allow for non-conservative forces. See the `min_style` command for details.

fix 1 flow viscous/sphere 0.1
fix 1 damp viscous/sphere 0.5 scale 3 2.5
fix 1 damp viscous/sphere 0.5 scale v_radscale

17.226.3 Description

Add a viscous damping torque to finite-size spherical particles in the group that is proportional to the angular velocity of the atom. In granular simulations this can be useful for draining the rotational kinetic energy from the system in a controlled fashion. If used without additional thermostating (to add kinetic energy to the system), it has the effect of slowly (or rapidly) freezing the system; hence it can also be used as a simple energy minimization technique.

The damping torque $T_i$ is given by $T_i = -\gamma \omega_i$. The larger the coefficient, the faster the rotational kinetic energy is reduced.

If the optional keyword scale is used, $\gamma$ can be scaled up or down by the specified factor for atoms. This factor can be set for different atom types and thus the scale keyword used multiple times followed by the atom type and the
associated scale factor. Alternately the scaling factor can be computed for each atom (e.g. based on its radius) by using an atom-style variable.

**Note:** You should specify gamma in torque/angular velocity units. This is not the same as mass/time units, at least for some of the LAMMPS units options like “real” or “metal” that are not self-consistent.

In the current implementation, rather than have the user specify a viscosity, $\gamma$ is specified directly in torque/angular velocity units. If needed, $\gamma$ can be adjusted for atoms of different sizes (i.e. $\sigma$) by using the `scale` keyword.

### 17.226.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the `start/stop` keywords of the `run` command.

The fix_modify `respa` option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is modifying torques. Default is the outermost level.

The torques due to this fix are imposed during an energy minimization, invoked by the `minimize` command. This fix should only be used with damped dynamics minimizers that allow for non-conservative forces. See the `min_style` command for details.

### 17.226.5 Restrictions

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This fix requires that atoms store torque and angular velocity (omega) and a radius as defined by the atom_style sphere command.

All particles in the group must be finite-size spheres. They cannot be point particles.

17.232.3 Description

Bound the simulation domain on one or more of its faces with a flat wall that interacts with the atoms in the group by generating a force on the atom in a direction perpendicular to the wall. The energy of wall-particle interactions depends on the style.

For style `wall/lj93`, the energy \( E \) is given by the 9/3 potential:

\[
E = \epsilon \left[ \frac{2}{15} \left( \frac{\sigma}{r} \right)^9 - \left( \frac{\sigma}{r} \right)^3 \right] \quad r < r_c
\]

For style `wall/lj126`, the energy \( E \) is given by the 12/6 potential:

\[
E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] \quad r < r_c
\]

For style `wall/lj1043`, the energy \( E \) is given by the 10/4/3 potential:

\[
E = 2\pi \epsilon \left[ \frac{2}{5} \left( \frac{\sigma}{r} \right)^{10} - \left( \frac{\sigma}{r} \right)^4 - \frac{\sqrt{2}\sigma^3}{3 \left( r + \left( \frac{0.61}{\sqrt{2}} \right) \sigma \right)^3} \right] \quad r < r_c
\]

For style `wall/colloid`, the energy \( E \) is given by an integrated form of the `pair_style colloid` potential:

\[
E = \epsilon \left[ \frac{\sigma_6^6}{7500} \left( \frac{6R - D}{D^7} + \frac{D + 8R}{(D + 2R)^7} - \frac{1}{6} \left( \frac{2R(D + R) + D(D + 2R) \ln D - \ln(D + 2R)}{D(D + 2R)} \right) \right) \right] \quad r < r_c
\]
For style wall/harmonic, the energy $E$ is given by a harmonic spring potential:

$$E = \epsilon (r - r_c)^2 \quad r < r_c$$

For style wall/morse, the energy $E$ is given by a Morse potential:

$$E = D_0 \left[ e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)} \right] \quad r < r_c$$

In all cases, $r$ is the distance from the particle to the wall at position coord, and $r_c$ is the cutoff distance at which the particle and wall no longer interact. The energy of the wall potential is shifted so that the wall-particle interaction energy is 0.0 at the cutoff distance.

Up to 6 walls or faces can be specified in a single command: xlo, xhi, ylo, yhi, zlo, zhi. A lo face interacts with particles near the lower side of the simulation box in that dimension. A hi face interacts with particles near the upper side of the simulation box in that dimension.

The position of each wall can be specified in one of 3 ways: as the EDGE of the simulation box, as a constant value, or as a variable. If EDGE is used, then the corresponding boundary of the current simulation box is used. If a numeric constant is specified then the wall is placed at that position in the appropriate dimension ($x$, $y$, or $z$). In both the EDGE and constant cases, the wall will never move. If the wall position is a variable, it should be specified as v_name, where name is an equal-style variable name. In this case the variable is evaluated each timestep and the result becomes the current epsilon or sigma of the wall.

The thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent wall position. See examples below.

For the wall/lj93 and wall/lj126 and wall/lj1043 styles, $\epsilon$ and $\sigma$ are the usual Lennard-Jones parameters, which determine the strength and size of the particle as it interacts with the wall. Epsilon has energy units. Note that this $\epsilon$ and $\sigma$ may be different than any $\epsilon$ or $\sigma$ values defined for a pair style that computes particle-particle interactions.

The wall/lj93 interaction is derived by integrating over a 3d half-lattice of Lennard-Jones 12/6 particles. The wall/lj126 interaction is effectively a harder, more repulsive wall interaction. The wall/lj1043 interaction is yet a different form of wall interaction, described in Magda et al in (Magda).

For the wall/colloid style, $R$ is the radius of the colloid particle, $D$ is the distance from the surface of the colloid particle to the wall ($r$-R), and $\sigma$ is the size of a constituent LJ particle inside the colloid particle and wall. Note that the cutoff distance $R_c$ in this case is the distance from the colloid particle center to the wall. The prefactor $\epsilon$ can be thought of as an effective Hamaker constant with energy units for the strength of the colloid-wall interaction. More specifically, the $\epsilon$ prefactor is $4\pi^2\rho_{wall}\rho_{colloid}\sigma^4$, where $\epsilon$ and $\sigma$ are the LJ parameters for the constituent LJ particles. $\rho_{wall}$ and $\rho_{colloid}$ are the number density of the constituent particles, in the wall and colloid respectively, in units of 1/volume.

The wall/colloid interaction is derived by integrating over constituent LJ particles of size $\sigma$ within the colloid particle and a 3d half-lattice of Lennard-Jones 12/6 particles of size $\sigma$ in the wall. As mentioned in the preceding paragraph, the density of particles in the wall and colloid can be different, as specified by the $\epsilon$ prefactor.

For the wall/harmonic style, $\epsilon$ is effectively the spring constant K, and has units (energy/distance^2). The input parameter $\sigma$ is ignored. The minimum energy position of the harmonic spring is at the cutoff. This is a repulsive-only spring since the interaction is truncated at the cutoff.

For the wall/morse style, the three parameters are in this order: $D_0$, the depth of the potential, $\alpha$ the width parameter, and $r_0$ the location of the minimum. $D_0$ has energy units, $\alpha$ inverse distance units, and $r_0$ distance units.

For any wall, the $\epsilon$ and/or $\sigma$ and/or $\alpha$ parameter can be specified as an equal-style variable, in which case it should be specified as v_name, where name is the variable name. As with a variable wall position, the variable is evaluated each timestep and the result becomes the current epsilon or sigma of the wall. Equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent wall interaction.

Note: For all of the styles, you must insure that $r$ is always > 0 for all particles in the group, or LAMMPS will generate an error. This means you cannot start your simulation with particles at the wall position coord ($r = 0$) or with particles
on the wrong side of the wall \((r < 0)\). For the \textit{wall/lj93} and \textit{wall/lj126} styles, the energy of the wall/particle interaction (and hence the force on the particle) blows up as \(r \to 0\). The \textit{wall/colloid} style is even more restrictive, since the energy blows up as \(D = r-R \to 0\). This means the finite-size particles of radius \(R\) must be a distance larger than \(R\) from the wall position \textit{coord}. The \textit{harmonic} style is a softer potential and does not blow up as \(r \to 0\), but you must use a large enough \(\epsilon\) that particles always remain on the correct side of the wall \((r > 0)\).

The \textit{units} keyword determines the meaning of the distance units used to define a wall position, but only when a numeric constant or variable is used. It is not relevant when EDGE is used to specify a face position. In the variable case, the variable is assumed to produce a value compatible with the \textit{units} setting you specify.

A \textit{box} value selects standard distance units as defined by the \textit{units} command, e.g. Angstroms for units = real or metal. A \textit{lattice} value means the distance units are in lattice spacings. The \textit{lattice} command must have been previously used to define the lattice spacings.

The \textit{fld} keyword can be used with a \textit{yes} setting to invoke the wall constraint before pairwise interactions are computed. This allows an implicit FLD model using \textit{pair_style lubricateU} to include the wall force in its calculations. If the setting is \textit{no}, wall forces are imposed after pairwise interactions, in the usual manner.

The \textit{pbc} keyword can be used with a \textit{yes} setting to allow walls to be specified in a periodic dimension. See the \textit{boundary} command for options on simulation box boundaries. The default for \textit{pbc} is \textit{no}, which means the system must be non-periodic when using a wall. But you may wish to use a periodic box. E.g. to allow some particles to interact with the wall via the \textit{fix group-ID}, and others to pass through it and wrap around a periodic box. In this case you should ensure that the wall if sufficiently far enough away from the box boundary. If you do not, then particles may interact with both the wall and with periodic images on the other side of the box, which is probably not what you want.

Here are examples of variable definitions that move the wall position in a time-dependent fashion using equal-style \textit{variables}. The wall interaction parameters (epsilon, sigma) could be varied with additional variable definitions.

```plaintext
variable ramp equal ramp(0,10)
fix 1 all wall xlo v_ramp 1.0 1.0 2.5

variable linear equal vdisplace(0,20)
fix 1 all wall xlo v_linear 1.0 1.0 2.5

variable wiggle equal swiggle(0.0,5.0,3.0)
fix 1 all wall xlo v_wiggle 1.0 1.0 2.5

variable wiggle equal cwiggle(0.0,5.0,3.0)
fix 1 all wall xlo v_wiggle 1.0 1.0 2.5
```

The \textit{ramp(lo,hi)} function adjusts the wall position linearly from \(lo\) to \(hi\) over the course of a run. The \textit{vdisplace(c0,velocity)} function does something similar using the equation \(\text{position} = c0 + \text{velocity} \times \text{delta}\), where \(\text{delta}\) is the elapsed time.

The \textit{swiggle(c0,A,period)} function causes the wall position to oscillate sinusoidally according to this equation, where \(\omega = 2 \pi / \text{period}\):

\[
\text{position} = c0 + A \sin(\omega \times \text{delta})
\]

The \textit{cwiggle(c0,A,period)} function causes the wall position to oscillate sinusoidally according to this equation, which will have an initial wall velocity of 0.0, and thus may impose a gentler perturbation on the particles:

\[
\text{position} = c0 + A (1 - \cos(\omega \times \text{delta}))
\]
17.232.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files.

The fix_modify energy option is supported by this fix to add the energy of interaction between atoms and all the specified walls to the global potential energy of the system as part of thermodynamic output. The default setting for this fix is fix_modify energy no.

The fix_modify virial option is supported by this fix to add the contribution due to the interaction between atoms and all the specified walls to both the global pressure and per-atom stress of the system via the compute pressure and compute stress/atom commands. The former can be accessed by thermodynamic output. The default setting for this fix is fix_modify virial no.

The fix_modify respa option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar energy and a global vector of forces, which can be accessed by various output commands. Note that the scalar energy is the sum of interactions with all defined walls. If you want the energy on a per-wall basis, you need to use multiple fix wall commands. The length of the vector is equal to the number of walls defined by the fix. Each vector value is the normal force on a specific wall. Note that an outward force on a wall will be a negative value for lo walls and a positive value for hi walls. The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the start/stop keywords of the run command.

The forces due to this fix are imposed during an energy minimization, invoked by the minimize command.

Note: If you want the atom/wall interaction energy to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the fix_modify energy option for this fix.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

17.233.2 Examples

```plaintext
fix 1 all wall/body/polygon 1000.0 20.0 5.0 xplane -10.0 10.0
```
17.233.3 Description

This fix is for use with 2d models of body particles of style rounded/polygon. It bounds the simulation domain with wall(s). All particles in the group interact with the wall when they are close enough to touch it. The nature of the interaction between the wall and the polygon particles is the same as that between the polygon particles themselves, which is similar to a Hookean potential. See the Howto body page for more details on using body particles.

The parameters $k_n$, $c_n$, $c_t$ have the same meaning and units as those specified with the pair_style body/rounded/polygon command.

The wallstyle can be planar or cylindrical. The 2 planar options specify a pair of walls in a dimension. Wall positions are given by $lo$ and $hi$. Either of the values can be specified as NULL if a single wall is desired. For a zcylinder wallstyle, the cylinder’s axis is at $x=y=0.0$, and the radius of the cylinder is specified.

Optionally, the wall can be moving, if the wiggle keyword is appended.

For the wiggle keyword, the wall oscillates sinusoidally, similar to the oscillations of particles which can be specified by the fix move command. This is useful in packing simulations of particles. The arguments to the wiggle keyword specify a dimension for the motion, as well as it’s amplitude and period. Note that if the dimension is in the plane of the wall, this is effectively a shearing motion. If the dimension is perpendicular to the wall, it is more of a shaking motion. A zcylinder wall can only be wiggled in the z dimension.

Each timestep, the position of a wiggled wall in the appropriate dim is set according to this equation:

$$\text{position} = \text{coord} + A - A \cos(\omega \delta)$$

where coord is the specified initial position of the wall, $A$ is the amplitude, $\omega$ is $2 \pi / \text{period}$, and $\delta$ is the time elapsed since the fix was specified. The velocity of the wall is set to the derivative of this expression.

17.233.4 Restart, fix_modify, output, run start/stop, minimize info

None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.233.5 Restrictions

This fix is part of the BODY package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

Any dimension (xy) that has a wall must be non-periodic.

```
fix 1 all wall/body/polyhedron 1000.0 20.0 5.0 xplane -10.0 10.0
```

17.234.3 Description

This fix is for use with 3d models of body particles of style rounded/polyhedron. It bounds the simulation domain with wall(s). All particles in the group interact with the wall when they are close enough to touch it. The nature of the interaction between the wall and the polygon particles is the same as that between the polygon particles themselves, which is similar to a Hookean potential. See the Howto body page for more details on using body particles.

The parameters \( k_n \), \( c_n \), \( c_t \) have the same meaning and units as those specified with the pair_style body/rounded/polyhedron command.

The wallstyle can be planar or cylindrical. The 3 planar options specify a pair of walls in a dimension. Wall positions are given by \( lo \) and \( hi \). Either of the values can be specified as NULL if a single wall is desired.

Optionally, the wall can be moving, if the wiggle keyword is appended.
For the *wiggle* keyword, the wall oscillates sinusoidally, similar to the oscillations of particles which can be specified by the *fix move* command. This is useful in packing simulations of particles. The arguments to the *wiggle* keyword specify a dimension for the motion, as well as its *amplitude* and *period*. Note that if the dimension is in the plane of the wall, this is effectively a shearing motion. If the dimension is perpendicular to the wall, it is more of a shaking motion.

Each timestep, the position of a wiggled wall in the appropriate *dim* is set according to this equation:

\[
\text{position} = \text{coord} + A - A \cos (\omega \delta)
\]

where \(\text{coord}\) is the specified initial position of the wall, \(A\) is the *amplitude*, \(\omega\) is \(2\pi / \text{period}\), and \(\delta\) is the time elapsed since the fix was specified. The velocity of the wall is set to the derivative of this expression.

```

17.236.3 Description

Fix `wall/ees` bounds the simulation domain on one or more of its faces with a flat wall that interacts with the ellipsoidal atoms in the group by generating a force on the atom in a direction perpendicular to the wall and a torque parallel with the wall. The energy of wall-particle interactions $E$ is given by:

$$E = \epsilon \left[ \frac{2\sigma_n^2 (7r^5 + 14r^3 \sigma_n^2 + 3r\sigma_n^4)}{945 (r^2 - \sigma_n^2)^7} - \frac{\sigma_n^6 \left( 2r\sigma_n^3 + \sigma_n^2 (r^2 - \sigma_n^2) \log \left[ \frac{r-\sigma_n}{r+\sigma_n} \right] \right)}{96\sigma_n^6 (r^2 - \sigma_n^2)^5} \right]$$

where $\sigma_n < r < r_c$

Introduced by Babadi and Ejtehadi in (Babadi). Here, $r$ is the distance from the particle to the wall at position `coord`, and $r_c$ is the `cutoff` distance at which the particle and wall no longer interact. Also, $\sigma_n$ is the distance between center of ellipsoid and the nearest point of its surface to the wall as shown below.
Details of using this command and specifications are the same as fix/wall command. You can also find an example in USER/ees/ under examples/ directory.

The prefactor $\epsilon$ can be thought of as an effective Hamaker constant with energy units for the strength of the ellipsoid-wall interaction. More specifically, the $\epsilon$ prefactor is

$$8\pi^2 \rho_{\text{wall}} \rho_{\text{ellipsoid}} \epsilon \sigma_a \sigma_b \sigma_c$$

where $\epsilon$ is the LJ energy parameter for the constituent LJ particles and $\sigma_a$, $\sigma_b$, and $\sigma_c$ are the radii of the ellipsoidal particles. $\rho_{\text{wall}}$ and $\rho_{\text{ellipsoid}}$ are the number density of the constituent particles, in the wall and ellipsoid respectively, in units of 1/volume.

Note: You must insure that $r$ is always bigger than $\sigma_n$ for all particles in the group, or LAMMPS will generate an error. This means you cannot start your simulation with particles touching the wall position coord ($r = \sigma_n$) or with particles penetrating the wall ($0 < r < \sigma_n$) or with particles on the wrong side of the wall ($r < 0$).

Fix wall/region/ees treats the surface of the geometric region defined by the region-ID as a bounding wall which interacts with nearby ellipsoidal particles according to the EES potential introduced above.

Other details of this command are the same as for the fix wall/region command. One may also find an example of using this fix in the examples/PACKAGES/ees/ directory.

### 17.236.4 Restart, fix_modify, output, run start/stop, minimize info

No information about these fixes are written to binary restart files.

The fix_modify energy option is supported by these fixes to add the energy of interaction between atoms and all the specified walls or region wall to the global potential energy of the system as part of thermodynamic output. The default settings for these fixes are fix_modify energy no.

The fix_modify respa option is supported by these fixes. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.
These fixes computes a global scalar and a global vector of forces, which can be accessed by various output commands. See the fix wall command for a description of the scalar and vector.

No parameter of these fixes can be used with the start/stop keywords of the run command.

The forces due to these fixes are imposed during an energy minimization, invoked by the minimize command.

**Note:** If you want the atom/wall interaction energy to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the fix_modify energy option for this fix.

### 17.236.5 Restrictions

These fixes are part of the EXTRA-FIX package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

These fixes requires that atoms be ellipsoids as defined by the atom_style ellipsoid command.

```
17.237.3 Description

Bound the simulation domain of a granular system with a frictional wall. All particles in the group interact with the wall when they are close enough to touch it.

The nature of the wall/particle interactions are determined by the fstyle setting. It can be any of the styles defined by the pair_style gran/* or the more general pair_style granular commands. Currently the options are hooke, hooke/history, or hertz/history for the former, and granular with all the possible options of the associated pair_coeff command for the latter. The equation for the force between the wall and particles touching it is the same as the corresponding equation on the pair_style gran/* and pair_style granular doc pages, in the limit of one of the two particles going to infinite radius and mass (flat wall). Specifically, \( \delta = \text{radius} - r = \text{overlap of particle with wall} \), \( m_{\text{eff}} = \text{mass of particle} \), and the effective radius of contact = \( \frac{R_i R_j}{R_i + R_j} \) is set to the radius of the particle.

The parameters \( K_n \), \( K_t \), \( \gamma_n \), \( \gamma_t \), \( \phi \), and the optional keyword limit_damping have the same meaning and units as those specified with the pair_style gran/* commands. This means a NULL can be used for either \( K_t \) or \( \gamma_t \) as described on that page. If a NULL is used for \( K_t \), then a default value is used where \( K_t = \frac{2}{7} K_n \). If a NULL is used for \( \gamma_t \), then a default value is used where \( \gamma_t = \frac{1}{2} \gamma_n \).

All the model choices for cohesion, tangential friction, rolling friction and twisting friction supported by the pair_style granular through its pair_coeff command are also supported for walls. These are discussed in greater detail on the doc page for pair_style granular.

Note that you can choose a different force styles and/or different values for the wall/particle coefficients than for particle/particle interactions. E.g. if you wish to model the wall as a different material.

Note: As discussed on the page for pair_style gran/*, versions of LAMMPS before 9Jan09 used a different equation for Hertzian interactions. This means Hertzian wall/particle interactions have also changed. They now include a \( \sqrt{\text{radius}} \) term which was not present before. Also the previous versions used \( K_n \) and \( K_t \) from the pairwise interaction and hardwired dampflag to 1, rather than letting them be specified directly. This means you can set the values of the wall/particle coefficients appropriately in the current code to reproduce the results of a previous Hertzian monodisperse calculation. For example, for the common case of a monodisperse system with particles of diameter 1, \( K_n \), \( K_t \), \( \gamma_n \), and \( \gamma_s \) should be set \( \sqrt{2.0} \) larger than they were previously.

The effective mass \( m_{\text{eff}} \) in the formulas listed on the pair_style granular page is the mass of the particle for particle/wall interactions (mass of wall is infinite). If the particle is part of a rigid body, its mass is replaced by the mass of the rigid body in those formulas. This is determined by searching for a fix rigid command (or its variants).

The wallstyle can be planar or cylindrical. The 3 planar options specify a pair of walls in a dimension. Wall positions are given by \( \text{lo} \) and \( \text{hi} \). Either of the values can be specified as NULL if a single wall is desired. For a zcylinder wallstyle, the cylinder’s axis is at \( x = y = 0.0 \), and the radius of the cylinder is specified.

Optionally, the wall can be moving, if the wiggle or shear keywords are appended. Both keywords cannot be used together.

For the wiggle keyword, the wall oscillates sinusoidally, similar to the oscillations of particles which can be specified by the fix move command. This is useful in packing simulations of granular particles. The arguments to the wiggle keyword specify a dimension for the motion, as well as it’s amplitude and period. Note that if the dimension is in the plane of the wall, this is effectively a shearing motion. If the dimension is perpendicular to the wall, it is more of a shaking motion. A zcylinder wall can only be wiggled in the z dimension.

Each timestep, the position of a wiggled wall in the appropriate \( \text{dim} \) is set according to this equation:

\[
\text{position} = \text{coord} + A - A \cos (\omega \times \text{delta})
\]

where \( \text{coord} \) is the specified initial position of the wall, \( A \) is the amplitude, \( \omega \) is \( 2 \pi \times \text{period} \), and \( \text{delta} \) is the time elapsed since the fix was specified. The velocity of the wall is set to the derivative of this expression.
For the *shear* keyword, the wall moves continuously in the specified dimension with velocity $v_{\text{shear}}$. The dimension must be tangential to walls with a planar *wall style*, e.g. in the $y$ or $z$ directions for an *xplane* wall. For *cylinder* walls, a dimension of $z$ means the cylinder is moving in the $z$-direction along its axis. A dimension of $x$ or $y$ means the cylinder is spinning around the $z$-axis, either in the clockwise direction for $v_{\text{shear}} > 0$ or counter-clockwise for $v_{\text{shear}} < 0$. In this case, $v_{\text{shear}}$ is the tangential velocity of the wall at whatever radius has been defined.

### 17.237.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the shear friction state of atoms interacting with the wall to *binary restart files*, so that a simulation can continue correctly if granular potentials with shear “history” effects are being used. See the *read_restart* command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

If the *contacts* option is used, this fix generates a per-atom array with 8 columns as output, containing the contact information for owned particles (nlocal on each processor). All columns in this per-atom array will be zero if no contact has occurred. The values of these columns are listed in the following table:

<table>
<thead>
<tr>
<th>Index</th>
<th>Value</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1.0 if particle is in contact with wall, 0.0 otherwise</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>Force $f_x$ exerted by the wall</td>
<td>force units</td>
</tr>
<tr>
<td>3</td>
<td>Force $f_y$ exerted by the wall</td>
<td>force units</td>
</tr>
<tr>
<td>4</td>
<td>Force $f_z$ exerted by the wall</td>
<td>force units</td>
</tr>
<tr>
<td>5</td>
<td>$x$-coordinate of contact point on wall</td>
<td>distance units</td>
</tr>
<tr>
<td>6</td>
<td>$y$-coordinate of contact point on wall</td>
<td>distance units</td>

17.238.3 Description

Treat the surface of the geometric region defined by the \textit{region-ID} as a bounding frictional wall which interacts with nearby finite-size granular particles when they are close enough to touch the wall. See the \texttt{fix wall/region} and \texttt{fix wall/gran} commands for related kinds of walls for non-granular particles and simpler wall geometries, respectively.

Here are snapshots of example models using this command. Corresponding input scripts can be found in examples/granregion. Movies of these simulations are here on the Movies page of the LAMMPS website.

The distance between a particle and the region boundary is the distance to the nearest point on the region surface. The force the wall exerts on the particle is along the direction between that point and the particle center, which is the direction normal to the surface at that point. Note that if the region surface is comprised of multiple “faces”, then each face can exert a force on the particle if it is close enough. E.g. for \texttt{region_style block}, a particle in the interior, near a corner of the block, could feel wall forces from 1, 2, or 3 faces of the block.

Regions are defined using the \texttt{region} command. Note that the region volume can be interior or exterior to the bounding surface, which will determine in which direction the surface interacts with particles, i.e. the direction of the surface normal. The exception to this is if one or more \texttt{open} options are specified for the region command, in which case particles interact with both the interior and exterior surfaces of regions.

Regions can either be primitive shapes (block, sphere, cylinder, etc) or combinations of primitive shapes specified via the \texttt{union} or \texttt{intersect} region styles. These latter styles can be used to construct particle containers with complex shapes.

Regions can also move dynamically via the \texttt{region} command keywords (move) and \texttt{rotate}, or change their shape by use of variables as inputs to the \texttt{region} command. If such a region is used with this fix, then the region surface will move in time in the corresponding manner.

\textbf{Note:} As discussed on the \texttt{region} command doc page, regions in LAMMPS do not get wrapped across periodic boundaries. It is up to you to ensure that the region location with respect to periodic or non-periodic boundaries is specified appropriately via the \texttt{region} and \texttt{boundary} commands when using a region as a wall that bounds particle motion.
Note: For primitive regions with sharp corners and/or edges (e.g. a block or cylinder), wall/particle forces are computed accurately for both interior and exterior regions. For union and intersect regions, additional sharp corners and edges may be present due to the intersection of the surfaces of 2 or more primitive volumes. These corners and edges can be of two types: concave or convex. Concave points/edges are like the corners of a cube as seen by particles in the interior of a cube. Wall/particle forces around these features are computed correctly. Convex points/edges are like the corners of a cube as seen by particles exterior to the cube, i.e. the points jut into the volume where particles are present. LAMMPS does NOT compute the location of these convex points directly, and hence wall/particle forces in the cutoff volume around these points suffer from inaccuracies. The basic problem is that the outward normal of the surface is not continuous at these points. This can cause particles to feel no force (they don't “see” the wall) when in one location, then move a distance epsilon, and suddenly feel a large force because they now “see” the wall. In a worst-case scenario, this can blow particles out of the simulation box. Thus, as a general rule you should not use the fix wall/gran/region command with union or intersect regions that have convex points or edges resulting from the union/intersection (convex points/edges in the union/intersection due to a single sub-region are still OK).

Note: Similarly, you should not define union or intersect regions for use with this command that share an overlapping common face that is part of the overall outer boundary (interior boundary is OK), even if the face is smooth. E.g. two regions of style block in a union region, where the two blocks overlap on one or more of their faces. This is because LAMMPS discards points that are part of multiple sub-regions when calculating wall/particle interactions, to avoid double-counting the interaction. Having two coincident faces could cause the face to become invisible to the particles. The solution is to make the two faces differ by epsilon in their position.

The nature of the wall/particle interactions are determined by the fstyle setting. It can be any of the styles defined by the pair_style gran/* or the more general pair_style granular commands. Currently the options are hooke, hooke/history, or hertz/history for the former, and granular with all the possible options of the associated pair_coeff command for the latter. The equation for the force between the wall and particles touching it is the same as the corresponding equation on the pair_style gran/* and pair_style granular doc pages, but the effective radius is calculated using the radius of the particle and the radius of curvature of the wall at the contact point.

Specifically, delta = radius - r = overlap of particle with wall, m_eff = mass of particle, and Rj/Ri+Rj is the effective radius, with Rj replaced by the radius of curvature of the wall at the contact point. The radius of curvature can be negative for a concave wall section, e.g. the interior of cylinder. For a flat wall, delta = radius - r = overlap of particle with wall, m_eff = mass of particle, and the effective radius of contact is just the radius of the particle.

The parameters Kn, Kt, gamma_n, gamma_t, xmu, dampflag, and the optional keyword limit_damping have the same meaning and units as those specified with the pair_style gran/* commands. This means a NULL can be used for either Kt or gamma_t as described on that page. If a NULL is used for Kt, then a default value is used where $Kt = 2/7 \ Kn$. If a NULL is used for gamma_t, then a default value is used where $gamma_t = 1/2 \ gamma_n$.

All the model choices for cohesion, tangential friction, rolling friction and twisting friction supported by the pair_style granular through its pair_coeff command are also supported for walls. These are discussed in greater detail on the doc page for pair_style granular.

Note that you can choose a different force styles and/or different values for the 6 wall/particle coefficients than for particle/particle interactions. E.g. if you wish to model the wall as a different material.
17.238.4 Restart, fix_modify, output, run start/stop, minimize info

Similar to fix wall/gran command, this fix writes the shear friction state of atoms interacting with the wall to binary restart files, so that a simulation can continue correctly if granular potentials with shear “history” effects are being used. This fix also includes info about a moving region in the restart file. See the read_restart command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

Note: Information about region definitions is NOT included in restart files, as discussed on the read_restart doc page. So you must re-define your region and if it is a moving region, define its motion attributes in a way that is consistent with the simulation that wrote the restart file. In particular, if you want to change the region motion attributes (e.g. its velocity), then you should ensure the position/orientation of the region at the initial restart timestep is the same as it was on the timestep the restart file was written. If this is not possible, you may need to ignore info in the restart file by defining a new fix wall/gran/region command in your restart script, e.g. with a different fix ID. Or if you want to keep the shear history info but discard the region motion information, you can use the same fix ID for fix wall/gran/region, but assign it a region with a different region ID.

If the contacts option is used, this fix generates a per-atom array with 8 columns as output, containing the contact information for owned particles (nlocal on each processor). All columns in this per-atom array will be zero if no contact has occurred. The values of these columns are listed in the following table:

<table>
<thead>
<tr>
<th>Index</th>
<th>Value</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1.0 if particle is in contact with wall, 0.0 otherwise</td>
<td></td>
</tr>
<tr>
<td>2</td>

fix walls all wall/piston zlo pos 1.0 vel 10.0 units box
fix top all wall/piston zlo vel 10.0 ramp
```

17.239.3 Description

Bound the simulation with a moving wall which reflect particles in the specified group and drive the system with an effective infinite-mass piston capable of driving shock waves.

A momentum mirror technique is used, which means that if an atom (or the wall) moves such that an atom is outside the wall on a timestep by a distance delta (e.g. due to `fix nve`), then it is put back inside the face by the same delta, and the velocity relative to the moving wall is flipped in z. For instance, a stationary particle hit with a piston wall with velocity `vz`, will end the timestep with a velocity of `2*vz`.

Currently the `face` keyword can only be `zlo`. This creates a piston moving in the positive z direction. Particles with z coordinate less than the wall position are reflected to a z coordinate greater than the wall position. If the piston velocity is `vpz` and the particle velocity before reflection is `vzi`, the particle velocity after reflection is `-vzi + 2*vpz`.
The initial position of the wall can be specified by the *pos* keyword.

The final velocity of the wall can be specified by the *vel* keyword.

The *ramp* keyword will cause the wall/piston to adjust the velocity linearly from zero velocity to *vel* over the course of the run. If the *ramp* keyword is omitted then the wall/piston moves at a constant velocity defined by *vel*.

The *temp* keyword will cause the region immediately in front of the wall/piston to be thermostatted with a Langevin thermostat. This region moves with the piston. The damping and kicking are measured in the reference frame of the piston. So, a temperature of zero would mean all particles were moving at exactly the speed of the wall/piston.

The *units* keyword determines the meaning of the distance units used to define a wall position, but only when a numeric constant is used.

A *box* value selects standard distance units as defined by the *units* command, e.g. Angstroms for units = real or metal. A *lattice* value means the distance units are in lattice spacings. The *lattice* command must have been previously used to define the lattice spacings.

### 17.239.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix_modify* options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various *output commands*. No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

### 17.239.5 Restrictions

This fix style is part of the SHOCK package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

The face that has the wall/piston must be boundary type ‘s’ (shrink-wrapped). The opposing face can be any boundary type other than periodic.

A wall/piston should not be used with rigid bodies such as those defined by a “fix rigid” command. This is because the wall/piston displaces atoms directly rather than exerting a force on them.

fix top all wall/reflect zhi v\_pressdown
\end{verbatim}

17.240.3 Description

Bound the simulation with one or more walls which reflect particles in the specified group when they attempt to move through them.

Reflection means that if an atom moves outside the wall on a timestep by a distance delta (e.g. due to \textit{fix nve}), then it is put back inside the face by the same delta, and the sign of the corresponding component of its velocity is flipped.

When used in conjunction with \textit{fix nve} and \textit{run_style verlet}, the resultant time-integration algorithm is equivalent to the primitive splitting algorithm (PSA) described by Bond. Because each reflection event divides the corresponding timestep asymmetrically, energy conservation is only satisfied to $O(\text{dt})$, rather than to $O(\text{dt}^2)$ as it would be for velocity-Verlet integration without reflective walls.

Up to 6 walls or faces can be specified in a single command: \textit{xlo}, \textit{xhi}, \textit{ylo}, \textit{yhi}, \textit{zlo}, \textit{zhi}. A \textit{lo} face reflects particles that move to a coordinate less than the wall position, back in the \textit{hi} direction. A \textit{hi} face reflects particles that move to a coordinate higher than the wall position, back in the \textit{lo} direction.

The position of each wall can be specified in one of 3 ways: as the \textit{EDGE} of the simulation box, as a constant value, or as a variable. If \textit{EDGE} is used, then the corresponding boundary of the current simulation box is used. If a numeric constant is specified then the wall is placed at that position in the appropriate dimension (\textit{x}, \textit{y}, or \textit{z}). In both the \textit{EDGE}
and constant cases, the wall will never move. If the wall position is a variable, it should be specified as v_name, where name is an equal-style variable name. In this case the variable is evaluated each timestep and the result becomes the current position of the reflecting wall. Equal-style variables can specify formulas with various mathematical functions, and include thermo_style command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent wall position.

The units keyword determines the meaning of the distance units used to define a wall position, but only when a numeric constant or variable is used. It is not relevant when EDGE is used to specify a face position. In the variable case, the variable is assumed to produce a value compatible with the units setting you specify.

A box value selects standard distance units as defined by the units command, e.g. Angstroms for units = real or metal. A lattice value means the distance units are in lattice spacings. The lattice command must have been previously used to define the lattice spacings.

Here are examples of variable definitions that move the wall position in a time-dependent fashion using equal-style variables.

```
variable ramp equal ramp(0,10)
fix 1 all wall/reflect xlo v_ramp

variable linear equal vdisplace(0,20)
fix 1 all wall/reflect xlo v_linear

variable wiggle equal swiggle(0.0,5.0,3.0)
fix 1 all wall/reflect xlo v_wiggle

variable wiggle equal cwiggle(0.0,5.0,3.0)
fix 1 all wall/reflect xlo v_wiggle
```

The ramp(lo,hi) function adjusts the wall position linearly from lo to hi over the course of a run. The vdisplace(c0,velocity) function does something similar using the equation position = c0 + velocity*delta, where delta is the elapsed time.

The swiggle(c0,A,period) function causes the wall position to oscillate sinusoidally according to this equation, where omega = 2 PI / period:

```
position = c0 + A sin(omega*delta)
```

The cwiggle(c0,A,period) function causes the wall position to oscillate sinusoidally according to this equation, which will have an initial wall velocity of 0.0, and thus may impose a gentler perturbation on the particles:

```
position = c0 + A (1 - cos(omega*delta))
```

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
17.240.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to binary restart files. None of the fix_modify options are relevant to this fix. No global or per-atom quantities are stored by this fix for access by various output commands. No parameter of this fix can be used with the start/stop keywords of the run command. This fix is not invoked during energy minimization.

17.240.5 Restrictions

Any dimension (xyz) that has a reflecting wall must be non-periodic.

A reflecting wall should not be used with rigid bodies such as those defined by a “fix rigid” command. This is because the wall/reflect displaces atoms directly rather than exerts a force on them. For rigid bodies, use a soft wall instead, such as fix wall/lj93. LAMMPS will flag the use of a rigid fix with fix wall/reflect with a warning, but will not generate an error.

```

17.241.3 Description

Bound the simulation with one or more walls which reflect particles in the specified group when they attempt to move through them.

Reflection means that if an atom moves outside the wall on a timestep (e.g. due to the `fix nve` command), then it is put back inside the wall with a changed velocity.

This fix models treats the wall as a moving solid boundary with a finite temperature, which can exchange energy with particles that collide with it. This is different than the simpler `fix wall/reflect` command which models mirror reflection. For this fix, the post collision velocity of each particle is treated stochastically. The randomness can come from many sources: thermal motion of the wall atoms, surface roughness, etc. Three stochastic reflection models are currently implemented.

For rstyle `diffusive`, particles are reflected diffusively. Their velocity distribution corresponds to an equilibrium distribution of particles at the wall temperature. No accommodation coefficients are specified.

For rstyle `maxwell`, particle reflection is Maxwellian which means partially diffusive and partially specular (Maxwell). A single accommodation coeff is specified which must be between 0.0 and 1.0 inclusive. It determines the fraction of the collision which is diffusive versus specular. An accommodation coefficient of 1.0 is fully diffusive; a coefficient of 0.0 is fully specular.

For rstyle `ccl`, particle collisions are computed by the Cercignani/Lampis model. See CL and To for details. Three accommodations coefficient are specified. Each must be between 0.0 and 1.0 inclusive. Two are velocity accommodation coefficients; one is a normal kinetic energy accommodation. The normal coeff is the one corresponding to the normal of the wall itself. For example if the wall is `ylo` or `yhi`, `accomx` and `accomz` are the tangential velocity accommodation coefficients, and `accomy` is the normal kinetic energy accommodation coefficient.

The optional `units` keyword determines the distance units used to define a wall position. A `box` value selects standard distance units as defined by the `units` command, e.g. Angstroms for units = real or metal. A `lattice` value means the distance units are in lattice spacings. The `lattice` command must have been previously used to define the lattice spacings.
17.241.4 Restrictions

This fix has the same limitations as the `fix wall/reflect` command. Any dimension (xyz) that has a wall must be non-periodic. It should not be used with rigid bodies such as those defined by the `fix rigid` command. The wall velocity must lie on the same plane as the wall itself.

This fix is part of the EXTRA-FIX package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

17.242.3 Description

Treat the surface of the geometric region defined by the `region-ID` as a bounding wall which interacts with nearby particles according to the specified style.

The distance between a particle and the surface is the distance to the nearest point on the surface and the force the wall exerts on the particle is along the direction between that point and the particle, which is the direction normal to the surface at that point. Note that if the region surface is comprised of multiple “faces”, then each face can exert a force on the particle if it is close enough. E.g. for `region_style block`, a particle in the interior, near a corner of the block, could feel wall forces from 1, 2, or 3 faces of the block.

Regions are defined using the `region` command. Note that the region volume can be interior or exterior to the bounding surface, which will determine in which direction the surface interacts with particles, i.e. the direction of the surface normal. The surface of the region only exerts forces on particles “inside” the region; if a particle is “outside” the region it will generate an error, because it has moved through the wall.

Regions can either be primitive shapes (block, sphere, cylinder, etc) or combinations of primitive shapes specified via the `union` or `intersect` region styles. These latter styles can be used to construct particle containers with complex shapes. Regions can also change over time via the `region` command keywords (move) and `rotate`. If such a region is used with this fix, then the of region surface will move over time in the corresponding manner.

Note: As discussed on the `region` command doc page, regions in LAMMPS do not get wrapped across periodic boundaries. It is up to you to insure that periodic or non-periodic boundaries are specified appropriately via the `boundary` command when using a region as a wall that bounds particle motion. This also means that if you embed a region in your simulation box and want it to repulse particles from its surface (using the “side out” option in the `region` command), that its repulsive force will not be felt across a periodic boundary.

Note: For primitive regions with sharp corners and/or edges (e.g. a block or cylinder), wall/particle forces are computed accurately for both interior and exterior regions. For `union` and `intersect` regions, additional sharp corners and edges may be present due to the intersection of the surfaces of 2 or more primitive volumes. These corners and edges can be of two types: concave or convex. Concave points/edges are like the corners of a cube as seen by particles in the interior of a cube. Wall/particle forces around these features are computed correctly. Convex points/edges are like the corners of a cube as seen by particles exterior to the cube, i.e. the points jut into the volume where particles are present. LAMMPS does NOT compute the location of these convex points directly, and hence wall/particle forces in the cutoff volume around these points suffer from inaccuracies. The basic problem is that the outward normal of the surface is not continuous at these points. This can cause particles to feel no force (they don’t “see” the wall) when in one location, then move a distance epsilon, and suddenly feel a large force because they now “see” the wall. In a worst-case scenario, this can blow particles out of the simulation box. Thus, as a general rule you should not use the fix wall/gran/region command with `union` or `intersect` regions that have convex points or edges resulting from the union/intersection (convex points/edges in the union/intersection due to a single sub-region are still OK).

Note: Similarly, you should not define `union` or `intersect` regions for use with this command that share an overlapping common face that is part of the overall outer boundary (interior boundary is OK), even if the face is smooth. E.g. two regions of style block in a `union` region, where the two blocks overlap on one or more of their faces. This is because
LAMMPS discards points that are part of multiple sub-regions when calculating wall/particle interactions, to avoid double-counting the interaction. Having two coincident faces could cause the facet to become invisible to the particles. The solution is to make the two faces differ by epsilon in their position.

The energy of wall-particle interactions depends on the specified style.

For style \textit{lj93}, the energy $E$ is given by the 9/3 potential:

$$ E = \epsilon \left[ \frac{2}{15} \left( \frac{\sigma}{r} \right)^9 - \left( \frac{\sigma}{r} \right)^3 \right] \quad r < r_c $$

For style \textit{lj126}, the energy $E$ is given by the 12/6 potential:

$$ E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] \quad r < r_c $$

For style \textit{wall/lj1043}, the energy $E$ is given by the 10/4/3 potential:

$$ E = 2\pi \epsilon \left[ \frac{2}{5} \left( \frac{\sigma}{r} \right)^{10} - \left( \frac{\sigma}{r} \right)^4 - \frac{\sqrt{2}\sigma^3}{3 \left( r + \left( 0.61/\sqrt{2} \right) \sigma \right)} \right] \quad r < r_c $$

For style \textit{colloid}, the energy $E$ is given by an integrated form of the pair_style \textit{colloid} potential:

$$ E = \epsilon \left[ \frac{\sigma^6}{7560} \left( \frac{6R - D}{D^7} + \frac{D + 8R}{(D + 2R)^7} \right) - \frac{\sqrt{2}\sigma^3}{6 \left( 2R(D + r) + D(D + 2R) \ln D - \ln(D + 2R) \right)} \right] \quad r < r_c $$

For style \textit{wall/harmonic}, the energy $E$ is given by a harmonic spring potential (the distance parameter is ignored):

$$ E = \epsilon (r - r_c)^2 \quad r < r_c $$

For style \textit{wall/morse}, the energy $E$ is given by the Morse potential:

$$ E = D_0 \left[ e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)} \right] \quad r < r_c $$

Unlike other styles, this requires three parameters ($D_0$, $\alpha$, and $r_0$ in this order) instead of two like for the other wall styles.

In all cases, $r$ is the distance from the particle to the region surface, and $r_c$ is the cutoff distance at which the particle and surface no longer interact. The cutoff is always the last argument. The energy of the wall potential is shifted so that the wall-particle interaction energy is 0.0 at the cutoff distance.

For a full description of these wall styles, see fix\_style wall

\section*{17.242.4 Restart, fix\_modify, output, run start/stop, minimize info}

No information about this fix is written to binary restart files.

The \textit{fix\_modify energy} option is supported by this fix to add the energy of interaction between atoms and the region wall to the global potential energy of the system as part of \textit{thermodynamic output}. The default setting for this fix is \textit{fix\_modify energy no}.

The \textit{fix\_modify virial} option is supported by this fix to add the contribution due to the interaction between atoms and the region wall to both the global pressure and per-atom stress of the system via the \textit{compute pressure} and \textit{compute pressure virial}.
The `stress/atom` commands. The former can be accessed by `thermodynamic output`. The default setting for this fix is `fix_modify virial no`.

The `fix_modify respa` option is supported by this fix. This allows to set at which level of the r-RESPA integrator the fix is adding its forces. Default is the outermost level.

This fix computes a global scalar energy and a global 3-length vector of forces, which can be accessed by various `output commands`. The scalar energy is the sum of energy interactions for all particles interacting with the wall represented by the region surface. The 3 vector quantities are the x,y,z components of the total force acting on the wall due to the particles. The scalar and vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command.

The forces due to this fix are imposed during an energy minimization, invoked by the `minimize` command.

**Note:** If you want the atom/wall interaction energy to be included in the total potential energy of the system (the quantity being minimized), you MUST enable the `fix_modify energy` option for this fix.

fix xwalls all wall/srd xlo EDGE xhi EDGE
fix walls all wall/srd xlo 0.0 ylo 10.0 units box
fix top all wall/srd zhi v_pressdown
```

### 17.243.3 Description

Bound the simulation with one or more walls which interact with stochastic reaction dynamics (SRD) particles as slip (smooth) or no-slip (rough) flat surfaces. The wall interaction is actually invoked via the `fix srd` command, only on the group of SRD particles it defines, so the group setting for the `fix wall/srd` command is ignored.

A particle/wall collision occurs if an SRD particle moves outside the wall on a timestep. This alters the position and velocity of the SRD particle and imparts a force to the wall.

The `collision` and `Tsrd` settings specified via the `fix srd` command affect the SRD/wall collisions. A slip setting for the `collision` keyword means that the tangential component of the SRD particle momentum is preserved. Thus only a normal force is imparted to the wall. The normal component of the new SRD velocity is sampled from a Gaussian distribution at temperature `Tsrd`.

For a noslip setting of the `collision` keyword, both the normal and tangential components of the new SRD velocity are sampled from a Gaussian distribution at temperature `Tsrd`. Additionally, a new tangential direction for the SRD velocity is chosen randomly. This collision style imparts both a normal and tangential force to the wall.

Up to 6 walls or faces can be specified in a single command: `xlo, xhi`, `ylo, yhi`, `zlo, zhi`. A `lo` face reflects particles that move to a coordinate less than the wall position, back in the `hi` direction. A `hi` face reflects particles that move to a coordinate higher than the wall position, back in the `lo` direction.

The position of each wall can be specified in one of 3 ways: as the EDGE of the simulation box, as a constant value, or as a variable. If EDGE is used, then the corresponding boundary of the current simulation box is used. If a numeric constant is specified then the wall is placed at that position in the appropriate dimension (x, y, or z). In both the EDGE and constant cases, the wall will never move. If the wall position is a variable, it should be specified as v_name, where name is an equal-style variable name. In this case the variable is evaluated each timestep and the result becomes the current position of the reflecting wall. Equal-style variables can specify formulas with various mathematical functions, and include `thermo_style` command keywords for the simulation box parameters and timestep and elapsed time. Thus it is easy to specify a time-dependent wall position.

**Note:** Because the trajectory of the SRD particle is tracked as it collides with the wall, you must insure that `r = distance of the particle from the wall`, is always `> 0` for SRD particles, or LAMMPS will generate an error. This means you cannot start your simulation with SRD particles at the wall position `coord (r = 0)` or with particles on the wrong side of the wall (`r < 0`).

**Note:** If you have 2 or more walls that come together at an edge or corner (e.g. walls in the x and y dimensions), then be sure to set the `overlap` keyword to `yes` in the `fix srd` command, since the walls effectively overlap when SRD particles...
collide with them. LAMMPS will issue a warning if you do not do this.

Note: The walls of this fix only interact with SRD particles, as defined by the `fix srd` command. If you are simulating a mixture containing other kinds of particles, then you should typically use another wall command to act on the other particles. Since SRD particles will be colliding both with the walls and the other particles, it is important to insure that the other particle's finite extent does not overlap an SRD wall. If you do not do this, you may generate errors when SRD particles end up “inside” another particle or a wall at the beginning of a collision step.

The `units` keyword determines the meaning of the distance units used to define a wall position, but only when a numeric constant is used. It is not relevant when EDGE or a variable is used to specify a face position.

A `box` value selects standard distance units as defined by the `units` command, e.g. Angstroms for units = real or metal. A `lattice` value means the distance units are in lattice spacings. The `lattice` command must have been previously used to define the lattice spacings.

Here are examples of variable definitions that move the wall position in a time-dependent fashion using equal-style variables.

```plaintext
variable ramp equal ramp(0,10)
fix 1 all wall/srd xlo v_ramp

variable linear equal vdisplace(0,20)
fix 1 all wall/srd xlo v_linear

variable wiggle equal swiggle(0.0,5.0,3.0)
fix 1 all wall/srd xlo v_wiggle

variable wiggle equal cwiggle(0.0,5.0,3.0)
fix 1 all wall/srd xlo v_wiggle
```

The `ramp(lo,hi)` function adjusts the wall position linearly from `lo` to `hi` over the course of a run. The `vdisplace(c0,velocity)` function does something similar using the equation `position = c0 + velocity*delta`, where `delta` is the elapsed time.

The `swiggle(c0,A,period)` function causes the wall position to oscillate sinusoidally according to this equation, where `omega = 2 PI / period`:

```
position = c0 + A sin(omega*delta)
```

The `cwiggle(c0,A,period)` function causes the wall position to oscillate sinusoidally according to this equation, which will have an initial wall velocity of 0.0, and thus may impose a gentler perturbation on the particles:

```
position = c0 + A (1 - cos(omega*delta))
```
17.243.4 Restart, fix_modify, output, run start/stop, minimize info

No information about this fix is written to *binary restart files*. None of the *fix_modify* options are relevant to this fix. 

This fix computes a global array of values which can be accessed by various *output commands*. The number of rows in the array is equal to the number of walls defined by the fix. The number of columns is 3, for the x,y,z components of force on each wall.

Note that an outward normal force on a wall will be a negative value for *lo* walls and a positive value for *hi* walls. The array values calculated by this fix are “extensive”.

No parameter of this fix can be used with the *start/stop* keywords of the *run* command. This fix is not invoked during *energy minimization*.

17.244.3 Description

This fix performs Widom insertions of atoms or molecules at the given temperature as discussed in (Frenkel). Specific uses include computation of Henry constants of small molecules in microporous materials or amorphous systems.

Every N timesteps the fix attempts M number of Widom insertions of atoms or molecules.

If the mol keyword is used, only molecule insertions are performed. Conversely, if the mol keyword is not used, only atom insertions are performed.

This command may optionally use the region keyword to define an insertion volume. The specified region must have been previously defined with a region command. It must be defined with side = in. Insertion attempts occur only within the specified region. For non-rectangular regions, random trial points are generated within the rectangular bounding box until a point is found that lies inside the region. If no valid point is generated after 1000 trials, no insertion is performed. If an attempted insertion places the atom or molecule center-of-mass outside the specified region, a new attempted insertion is generated. This process is repeated until the atom or molecule center-of-mass is inside the specified region.

Note that neighbor lists are re-built every timestep that this fix is invoked, so you should not set N to be too small. See the neighbor command for details.

When an atom or molecule is to be inserted, its coordinates are chosen at a random position within the current simulation cell or region. Relative coordinates for atoms in a molecule are taken from the template molecule provided by the user. The center of mass of the molecule is placed at the insertion point. The orientation of the molecule is chosen at random by rotating about this point.

Individual atoms are inserted, unless the mol keyword is used. It specifies a template-ID previously defined using the molecule command, which reads a file that defines the molecule. The coordinates, atom types, charges, etc., as well as any bonding and special neighbor information for the molecule can be specified in the molecule file. See the molecule command for details. The only settings required to be in this file are the coordinates and types of atoms in the molecule.

Note that fix widom does not use configurational bias MC or any other kind of sampling of intramolecular degrees of freedom. Inserted molecules can have different orientations, but they will all have the same intramolecular configuration, which was specified in the molecule command input.

For atoms, inserted particles have the specified atom type. For molecules, they use the same atom types as in the template molecule supplied by the user.

The excess chemical potential \( \mu_{ex} \) is defined as:

\[
\mu_{ex} = -kT \ln(< \exp(-(U_{N+1} - U_N)/kT) >)
\]

where \( k \) is Boltzman’s constant, \( T \) is the user-specified temperature, \( U_N \) and \( U_{N+1} \) is the potential energy of the system with \( N \) and \( N+1 \) particles.

The full_energy option means that the fix calculates the total potential energy of the entire simulated system, instead of just the energy of the part that is changed. By default, this option is off, in which case only partial energies are computed to determine the energy difference due to the proposed change.

The full_energy option is needed for systems with complicated potential energy calculations, including the following:

17.244. fix widom command
• long-range electrostatics (kspace)
• many-body pair styles
• hybrid pair styles
• eam pair styles
• tail corrections
• need to include potential energy contributions from other fixes

In these cases, LAMMPS will automatically apply the `full_energy` keyword and issue a warning message.

When the `mol` keyword is used, the `full_energy` option also includes the intramolecular energy of inserted and deleted molecules, whereas this energy is not included when `full_energy` is not used. If this is not desired, the `intra_energy` keyword can be used to define an amount of energy that is subtracted from the final energy when a molecule is inserted, and subtracted from the initial energy when a molecule is deleted. For molecules that have a non-zero intramolecular energy, this will ensure roughly the same behavior whether or not the `full_energy` option is used.

Some fixes have an associated potential energy. Examples of such fixes include: `efield`, `gravity`, `addforce`, `restrain`, and `wall fixes`. For that energy to be included in the total potential energy of the system (the quantity used when performing Widom insertions), you MUST enable the `fix_modify energy` option for that fix. The doc pages for individual fix commands specify if this should be done.

Use the `charge` option to insert atoms with a user-specified point charge. Note that doing so will cause the system to become non-neutral. LAMMPS issues a warning when using long-range electrostatics (kspace) with non-neutral systems. See the `compute group/group` documentation for more details about simulating non-neutral systems with kspace on.

### 17.244.4 Restart, fix_modify, output, run start/stop, minimize info

This fix writes the state of the fix to binary restart files. This includes information about the random number generator seed, the next timestep for Widom insertions etc. See the `read_restart` command for info on how to re-specify a fix in an input script that reads a restart file, so that the operation of the fix continues in an uninterrupted fashion.

**Note:** For this to work correctly, the timestep must **not** be changed after reading the restart with `reset_timestep`. The fix will try to detect it and stop with an error.

None of the `fix_modify` options are relevant to this fix.

This fix computes a global vector of length 3, which can be accessed by various output commands. The vector values are the following global cumulative quantities:

- 1 = average excess chemical potential on each timestep
- 2 = average difference in potential energy on each timestep
- 3 = volume of the insertion region

The vector values calculated by this fix are “extensive”.

No parameter of this fix can be used with the `start/stop` keywords of the `run` command. This fix is not invoked during `energy minimization`. 
17.244.5 Restrictions

This fix is part of the MC package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Do not set “neigh_modify once yes” or else this fix will never be called. Rereighboring is required.

Can be run in parallel, but aspects of the GCMC part will not scale well in parallel. Only usable for 3D simulations.

17.244.6 Related commands

fix gcmc fix atom/swap, neighbor, fix deposit, fix evaporate,

17.244.7 Default

The option defaults are mol = no, intra_energy = 0.0 and full_energy = no, except for the situations where full_energy is required, as listed above.

18.1 compute ackland/atom command

18.1.1 Syntax

\begin{verbatim}
compute ID group-ID ackland/atom keyword/value
\end{verbatim}

- ID, group-ID are documented in compute command
- ackland/atom = style name of this compute command
- zero or more keyword/value pairs may be appended
- keyword = legacy

\textit{legacy yes/no} = use (yes) or do not use (no) legacy ackland algorithm implementation

18.1.2 Examples

\begin{verbatim}
compute 1 all ackland/atom
compute 1 all ackland/atom legacy yes
\end{verbatim}

18.1.3 Description

Defines a computation that calculates the local lattice structure according to the formulation given in \textit{(Ackland)}. Historically, LAMMPS had two, slightly different implementations of the algorithm from the paper. With the \textit{legacy} keyword, it is possible to switch between the pre-2015 \textit{(legacy yes)} and post-2015 implementation \textit{(legacy no)}. The post-2015 variant is the default.

In contrast to the \textit{centro-symmetry parameter} this method is stable against temperature boost, because it is based not on the distance between particles but the angles. Therefore statistical fluctuations are averaged out a little more. A comparison with the Common Neighbor Analysis metric is made in the paper.

The result is a number which is mapped to the following different lattice structures:

- 0 = UNKNOWN
- 1 = BCC
- 2 = FCC
- 3 = HCP
The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently or to have multiple compute/dump commands, each of which computes this quantity.

18.1.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

18.1.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

The per-atom vector values will be unitless since they are the integers defined above.

compute 1 fluid adf 32 1*2 1*2 1*2 0.5 3.5
compute 1 fluid adf 32
```

18.2.3 Description

Define a computation that calculates one or more angular distribution functions (ADF) for a group of particles. Each ADF is calculated in histogram form by measuring the angle formed by a central atom and two neighbor atoms and binning these angles into Nbin bins. Only neighbors for which $R_{inner} < R < R_{outer}$ are counted, where $R_{inner}$ and $R_{outer}$ are specified separately for the first and second neighbor atom in each requested ADF.

**Note:** If you have a bonded system, then the settings of `special_bonds` command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the `special_bonds` command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses a neighbor list, it also means those pairs will not be included in the ADF. This does not apply when using long-range coulomb interactions (`coul/long`, `coul/msm`, `coul/wolf`) or similar. One way to get around this would be to set `special_bonds` scaling factors to very tiny numbers that are not exactly zero (e.g. 1.0e-50). Another workaround is to write a dump file, and use the `rerun` command to compute the ADF for snapshots in the dump file. The rerun script can use a `special_bonds` command that includes all pairs in the neighbor list.

**Note:** If you request any outer cutoff $R_{outer} >$ force cutoff, or if no pair style is defined, e.g. the `rerun` command is being used to post-process a dump file of snapshots you must insure ghost atom information out to the largest value of $R_{outer} + skin$ is communicated, via the `comm_modify cutoff` command, else the ADF computation cannot be performed, and LAMMPS will give an error message. The `skin` value is what is specified with the `neighbor` command.

The `itypeN,jtypeN,ktypeN` settings can be specified in one of two ways. An explicit numeric value can be used, as in the first example above. Or a wild-card asterisk can be used to specify a range of atom types as in the second example above. This takes the form `*n` or `*n*` or `n*n`. If $N = \text{the number of atom types}$, then an asterisk with no numeric values means all types from 1 to $N$. A leading asterisk means all types from 1 to $n$ (inclusive). A trailing asterisk means all types from $n$ to $N$ (inclusive). A middle asterisk means all types from $m$ to $n$ (inclusive).

If `itypeN`, `jtypeN`, and `ktypeN` are single values, as in the first example above, this means that the ADF is computed where atoms of type `itypeN` are the central atom, and neighbor atoms of type `jtypeN` and `ktypeN` are forming the angle. If any of `itypeN`, `jtypeN`, or `ktypeN` represent a range of values via the wild-card asterisk, as in the second example above, this means that the ADF is computed where atoms of any of the range of types represented by `itypeN` are the
central atom, and the angle is formed by two neighbors, one neighbor in the range of types represented by \textit{jtypeN} and another neighbor in the range of types represented by \textit{ktypeN}.

If no \textit{itypeN}, \textit{jtypeN}, \textit{ktypeN} settings are specified, then LAMMPS will generate a single ADF for all atoms in the group. The inner cutoff is set to zero and the outer cutoff is set to the force cutoff. If no \textit{pair_style} is specified, there is no force cutoff and LAMMPS will give an error message. Note that in most cases, generating an ADF for all atoms is not a good thing. Such an ADF is both uninformative and extremely expensive to compute. For example, with liquid water with a 10 Å force cutoff, there are 80,000 angles per atom. In addition, most of the interesting angular structure occurs for neighbors that are the closest to the central atom, involving just a few dozen angles.

Angles for each ADF are generated by double-looping over the list of neighbors of each central atom \textit{I}, just as they would be in the force calculation for a three-body potential such as Stillinger-Weber. The angle formed by central atom \textit{I} and neighbor atoms \textit{J} and \textit{K} is included in an ADF if the following criteria are met:

- atoms I,J,K are all in the specified compute group
- the distance between atoms I,J is between \textit{Rjinner} and \textit{Rjouter}
- the distance between atoms I,K is between \textit{Rkinner} and \textit{Rkouter}
- the type of the I atom matches \textit{itypeN} (one or a range of types)
- atoms I,J,K are distinct
- the type of the J atom matches \textit{jtypeN} (one or a range of types)
- the type of the K atom matches \textit{ktypeN} (one or a range of types)

Each unique angle satisfying the above criteria is counted only once, regardless of whether either or both of the neighbor atoms making up the angle appear in both the J and K lists. It is OK if a particular angle is included in more than one individual histogram, due to the way the \textit{itypeN}, \textit{jtypeN}, \textit{ktypeN} arguments are specified.

The first ADF value for a bin is calculated from the histogram count by dividing by the total number of triples satisfying the criteria, so that the integral of the ADF w.r.t. angle is 1, i.e. the ADF is a probability density function.

The second ADF value is reported as a cumulative sum of all bins up to the current bins, averaged over atoms of type \textit{itypeN}. It represents the number of angles per central atom with angle less than or equal to the angle of the current bin, analogous to the coordination number radial distribution function.

The \textit{ordinate} optional keyword determines whether the bins are of uniform angular size from zero to 180 (degree), zero to \textit{Pi} (radian), or the cosine of the angle uniform in the range [-1,1] (cosine). \textit{cosine} has the advantage of eliminating the \texttt{acos()} function call, which speeds up the compute by 2-3x, and it is also preferred on physical grounds, because the for uniformly distributed particles in 3D, the angular probability density w.r.t d\textit{theta} is \texttt{sin(theta)/2}, while for d(cos\texttt{(theta)}), it is 1/2. Regardless of which ordinate is chosen, the first column of ADF values is normalized w.r.t. the range of that ordinate, so that the integral is 1.

The simplest way to output the results of the compute adf calculation to a file is to use the \texttt{fix ave/time} command, for example:

```
compute myADF all adf 32 2 2 0.5 3.5 0.5 3.5
fix 1 all ave/time 100 1 100 c_myADF[*] file tmp.adf mode vector
```
18.2.4 Output info

This compute calculates a global array with the number of rows = \( N_{bins} \), and the number of columns = \( 1 + 2 \times N_{triples} \), where \( N_{triples} \) is the number of \( i,j,k \) triples specified. The first column has the bin coordinate (angle-related ordinate at midpoint of bin). Each subsequent column has the two ADF values for a specific set of \((i_{typeN},j_{typeN},k_{typeN})\) interactions, as described above. These values can be used by any command that uses a global values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The array values calculated by this compute are all “intensive”.

The first column of array values is the angle-related ordinate, either the angle in degrees or radians, or the cosine of the angle. Each subsequent pair of columns gives the first and second kinds of ADF for a specific set of \((i_{typeN},j_{typeN},k_{typeN})\). The values in the first ADF column are normalized numbers \( \geq 0.0 \), whose integral w.r.t. the ordinate is 1, i.e. the first ADF is a normalized probability distribution. The values in the second ADF column are also numbers \( \geq 0.0 \). They are the cumulative density distribution of angles per atom. By definition, this ADF is monotonically increasing from zero to a maximum value equal to the average total number of angles per atom satisfying the ADF criteria.

18.2.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

The ADF is not computed for neighbors outside the force cutoff, since processors (in parallel) don’t know about atom coordinates for atoms further away than that distance. If you want an ADF for larger distances, you can use the rerun command to post-process a dump file and set the cutoff for the potential to be longer in the rerun script. Note that in the rerun context, the force cutoff is arbitrary, since you are not running dynamics and thus are not changing your model.

18.2.6 Related commands

compute rdf, fix ave/time, compute_modify

18.2.7 Default

The keyword default is ordinate = degree.

18.3 compute angle command

18.3.1 Syntax

\[
\text{compute ID group-ID angle}
\]

- ID, group-ID are documented in compute command
- angle = style name of this compute command
18.3.2 Examples

```
compute 1 all angle
```

18.3.3 Description

Define a computation that extracts the angle energy calculated by each of the angle sub-styles used in the `angle_style hybrid` command. These values are made accessible for output or further processing by other commands. The group specified for this command is ignored.

This compute is useful when using `angle_style hybrid` if you want to know the portion of the total energy contributed by one or more of the hybrid sub-styles.

18.3.4 Output info

This compute calculates a global vector of length N where N is the number of sub_styles defined by the `angle_style hybrid` command, which can be accessed by indices 1-N. These values can be used by any command that uses global scalar or vector values from a compute as input. See the `Howto output` page for an overview of LAMMPS output options.

The vector values are “extensive” and will be in energy units.

18.3.5 Restrictions

18.4 compute angle/local command

18.4.1 Syntax

```
compute ID group-ID angle/local value1 value2 ... keyword args ...
```

- ID, group-ID are documented in `compute` command
- angle/local = style name of this compute command
- one or more values may be appended
- value = theta or eng or v_name
theta = tabulate angles
eng = tabulate angle energies
v_name = equal-style variable with name (see below)

• zero or more keyword/args pairs may be appended
• keyword = set
  set args = theta name
  theta = only currently allowed arg
  name = name of variable to set with theta

18.4.2 Examples

```plaintext
compute 1 all angle/local theta
compute 1 all angle/local eng theta
compute 1 all angle/local theta v_cos set theta t
```

18.4.3 Description

Define a computation that calculates properties of individual angle interactions. The number of datums generated, aggregated across all processors, equals the number of angles in the system, modified by the group parameter as explained below.

The value `theta` is the angle for the 3 atoms in the interaction.

The value `eng` is the interaction energy for the angle.

The value `v_name` can be used together with the `set` keyword to compute a user-specified function of the angle `theta`. The `name` specified for the `v_name` value is the name of an equal-style variable which should evaluate a formula based on a variable which will store the angle `theta`. This other variable must be an internal-style variable defined in the input script; its initial numeric value can be anything. It must be an internal-style variable, because this command resets its value directly. The `set` keyword is used to identify the name of this other variable associated with `theta`.

Note that the value of `theta` for each angle which stored in the internal variable is in radians, not degrees.

As an example, these commands can be added to the bench/in.rhodo script to compute the cosine and cosine^2 of every angle in the system and output the statistics in various ways:

```plaintext
variable t internal 0.0
variable cos equal cos(v_t)
variable cossq equal cos(v_t)*cos(v_t)

compute 1 all property/local aatom1 aatom2 aatom3 atype
compute 2 all angle/local eng theta v_cos v_cossq set theta t
dump 1 all local 100 tmp.dump c_1[*] c_2[*]
compute 3 all reduce ave c_2[*]
thermo_style custom step temp press c_3[*]
fix 10 all ave/histo 10 10 100 -1 1 20 c_2[3] mode vector file tmp.histo
```

The `dump local` command will output the energy, angle, cosine(angle), cosine^2(angle) for every angle in the system. The `thermo_style` command will print the average of those quantities via the `compute reduce` command with thermo output. And the `fix ave/histo` command will histogram the cosine(angle) values and write them to a file.

18.4. compute angle/local command
The local data stored by this command is generated by looping over all the atoms owned on a processor and their angles. An angle will only be included if all 3 atoms in the angle are in the specified compute group. Any angles that have been broken (see the \texttt{angle_style} command) by setting their angle type to 0 are not included. Angles that have been turned off (see the \texttt{fix shake} or \texttt{delete_bonds} commands) by setting their angle type negative are written into the file, but their energy will be 0.0.

Note that as atoms migrate from processor to processor, there will be no consistent ordering of the entries within the local vector or array from one timestep to the next. The only consistency that is guaranteed is that the ordering on a particular timestep will be the same for local vectors or arrays generated by other compute commands. For example, angle output from the \texttt{compute property/local} command can be combined with data from this command and output by the \texttt{dump local} command in a consistent way.

Here is an example of how to do this:

\begin{verbatim}
compute 1 all property/local atype aatom1 aatom2 aatom3
compute 2 all angle/local theta eng
\end{verbatim}

\subsection{18.4.4 Output info}

This compute calculates a local vector or local array depending on the number of values. The length of the vector or number of rows in the array is the number of angles. If a single value is specified, a local vector is produced. If two or more values are specified, a local array is produced where the number of columns = the number of values. The vector or array can be accessed by any command that uses local values from a compute as input. See the \textit{Howto output} page for an overview of LAMMPS output options.

The output for \texttt{theta} will be in degrees. The output for \texttt{eng} will be in energy \textit{units}.

\subsection{18.4.5 Restrictions}

\subsection{18.4.7 Default}

\texttt{none}
18.5 compute angmom/chunk command

18.5.1 Syntax

compute ID group-ID angmom/chunk chunkID

- ID, group-ID are documented in compute command
- angmom/chunk = style name of this compute command
- chunkID = ID of compute chunk/atom command

18.5.2 Examples

compute 1 fluid angmom/chunk molchunk

18.5.3 Description

Define a computation that calculates the angular momentum of multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a compute chunk/atom command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the compute chunk/atom and Howto chunk doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the 3 components of the angular momentum vector for each chunk, due to the velocity/momentum of the individual atoms in the chunk around the center-of-mass of the chunk. The calculation includes all effects due to atoms passing through periodic boundaries.

Note that only atoms in the specified group contribute to the calculation. The compute chunk/atom command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

Note: The coordinates of an atom contribute to the chunk’s angular momentum in “unwrapped” form, by using the image flags associated with each atom. See the dump custom command for a discussion of “unwrapped” coordinates. See the Atoms section of the read_data command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the set image command.

The simplest way to output the results of the compute angmom/chunk calculation to a file is to use the fix ave/time command, for example:

compute cc1 all chunk/atom molecule
compute myChunk all angmom/chunk cc1
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector

18.5. compute angmom/chunk command
18.5.4 Output info

This compute calculates a global array where the number of rows = the number of chunks $N_{chunk}$ as calculated by the specified compute chunk/atom command. The number of columns = 3 for the 3 xyz components of the angular momentum for each chunk. These values can be accessed by any command that uses global array values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in mass-velocity-distance units.

18.5.5 Restrictions

18.6 compute ave/sphere/atom command

Accelerator Variants: ave/sphere/atom/kk

18.6.1 Syntax

```plaintext
compute ID group-ID ave/sphere/atom keyword values ...
```

- ID, group-ID are documented in compute command
- ave/sphere/atom = style name of this compute command
- one or more keyword/value pairs may be appended
  ```plaintext
  keyword = cutoff
cutoff value = distance cutoff
  ```

18.6.2 Examples

```plaintext
compute 1 all ave/sphere/atom
compute 1 all ave/sphere/atom cutoff 5.0
comm_modify cutoff 5.0
```
18.6.3 Description

Define a computation that calculates the local mass density and temperature for each atom based on its neighbors inside a spherical cutoff. If an atom has M neighbors, then its local mass density is calculated as the sum of its mass and its M neighbor masses, divided by the volume of the cutoff sphere (or circle in 2d). The local temperature of the atom is calculated as the temperature of the collection of M+1 atoms, after subtracting the center-of-mass velocity of the M+1 atoms from each of the M+1 atom’s velocities. This is effectively the thermal velocity of the neighborhood of the central atom, similar to compute temp/com.

The optional keyword cutoff defines the distance cutoff used when searching for neighbors. The default value is the cutoff specified by the pair style. If no pair style is defined, then a cutoff must be defined using this keyword. If the specified cutoff is larger than that of the pair_style plus neighbor skin (or no pair style is defined), the comm_modify cutoff option must also be set to match that of the cutoff keyword.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently.

Note: If you have a bonded system, then the settings of special_bonds command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the special_bonds command, and means those pairwise interactions do not appear in the neighbor list. Because this compute uses the neighbor list, it also means those pairs will not be included in the order parameter. This difficulty can be circumvented by writing a dump file, and using the rerun command to compute the order parameter for snapshots in the dump file. The rerun script can use a special_bonds command that includes all pairs in the neighbor list.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

18.6.4 Output info

This compute calculates a per-atom array with two columns: mass density in density units and temperature in temperature units.

These values can be accessed by any command that uses per-atom values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.
18.6.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

18.6.6 Related commands

comm_modify

18.6.7 Default

The option defaults are cutoff = pair style cutoff.

18.7 compute basal/atom command

18.7.1 Syntax

```
compute ID group-ID basal/atom
```

- ID, group-ID are documented in compute command
- basal/atom = style name of this compute command

18.7.2 Examples

```
compute 1 all basal/atom
```

18.7.3 Description

Defines a computation that calculates the hexagonal close-packed “c” lattice vector for each atom in the group. It does this by calculating the normal unit vector to the basal plane for each atom. The results enable efficient identification and characterization of twins and grains in hexagonal close-packed structures.

The output of the compute is thus the 3 components of a unit vector associated with each atom. The components are set to 0.0 for atoms not in the group.

Details of the calculation are given in (Barrett).

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently or to have multiple compute/dump commands, each of which computes this quantity.

An example input script that uses this compute is provided in examples/PACKAGES/basal.
18.7.4 Output info

This compute calculates a per-atom array with 3 columns, which can be accessed by indices 1-3 by any command that uses per-atom values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

The per-atom vector values are unitless since the 3 columns represent components of a unit vector.

18.7.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

The output of this compute will be meaningless unless the atoms are on (or near) hcp lattice sites, since the calculation assumes a well-defined basal plane.

18.8 compute body/local command

18.8.1 Syntax

```
compute ID group-ID body/local input1 input2 ...
```

- ID, group-ID are documented in *compute* command
- body/local = style name of this compute command
- one or more keywords may be appended
- keyword = *id* or *type* or *integer*
  
  *id* = atom ID of the body particle
  *type* = atom type of the body particle
  *integer* = 1,2,3,etc = index of fields defined by body style
18.8.2 Examples

```
compute 1 all body/local type 1 2 3
compute 1 all body/local 3 6
```

18.8.3 Description

Define a computation that calculates properties of individual body sub-particles. The number of datums generated, aggregated across all processors, equals the number of body sub-particles plus the number of non-body particles in the system, modified by the group parameter as explained below. See the Howto body page for more details on using body particles.

The local data stored by this command is generated by looping over all the atoms. An atom will only be included if it is in the group. If the atom is a body particle, then its N sub-particles will be looped over, and it will contribute N datums to the count of datums. If it is not a body particle, it will contribute 1 datum.

For both body particles and non-body particles, the id keyword will store the ID of the particle. For both body particles and non-body particles, the type keyword will store the type of the particle.

The integer keywords mean different things for body and non-body particles. If the atom is not a body particle, only its x, y, z coordinates can be referenced, using the integer keywords 1,2,3. Note that this means that if you want to access more fields than this for body particles, then you cannot include non-body particles in the group.

For a body particle, the integer keywords refer to fields calculated by the body style for each sub-particle. The body style, as specified by the atom_style body, determines how many fields exist and what they are. See the Howto body doc page for details of the different styles.

Here is an example of how to output body information using the dump local command with this compute. If fields 1,2,3 for the body sub-particles are x,y,z coordinates, then the dump file will be formatted similar to the output of a dump atom or custom command.

```
compute 1 all body/local type 1 2 3
```

18.8.4 Output info

This compute calculates a local vector or local array depending on the number of keywords. The length of the vector or number of rows in the array is the number of datums as described above. If a single keyword is specified, a local vector is produced. If two or more keywords are specified, a local array is produced where the number of columns = the number of keywords. The vector or array can be accessed by any command that uses local values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The units for output values depend on the body style.

18.9 compute bond command

18.9.1 Syntax

```
compute ID group-ID bond
```

- ID, group-ID are documented in `compute` command
- bond = style name of this compute command

18.9.2 Examples

```
compute 1 all bond
```

18.9.3 Description

Define a computation that extracts the bond energy calculated by each of the bond sub-styles used in the `bond_style hybrid` command. These values are made accessible for output or further processing by other commands. The group specified for this command is ignored.

This compute is useful when using `bond_style hybrid` if you want to know the portion of the total energy contributed by one or more of the hybrid sub-styles.

18.9.4 Output info

This compute calculates a global vector of length N where N is the number of sub_styles defined by the `bond_style hybrid` command, which can be accessed by indices 1-N. These values can be used by any command that uses global scalar or vector values from a compute as input. See the `Howto output` page for an overview of LAMMPS output options.

The vector values are “extensive” and will be in energy units.

- engpot = bond potential energy
- force = bond force
- dx, dy, dz = components of pairwise distance
- fx, fy, fz = components of bond force
- engvib = bond kinetic energy of vibration
- engrot = bond kinetic energy of rotation
- engtrans = bond kinetic energy of translation
- omega = magnitude of bond angular velocity
- velvib = vibrational velocity along the bond length
- v_name = equal-style variable with name (see below)
  - zero or more keyword/args pairs may be appended
  - keyword = set
- set args = dist name
  - dist = only currently allowed arg
  - name = name of variable to set with distance (dist)
18.10.2 Examples

```
compute 1 all bond/local engpot
compute 1 all bond/local dist engpot force
compute 1 all bond/local dist fx fy fz
compute 1 all angle/local dist v_distsq set dist d
```

18.10.3 Description

Define a computation that calculates properties of individual bond interactions. The number of datums generated, aggregated across all processors, equals the number of bonds in the system, modified by the group parameter as explained below.

All these properties are computed for the pair of atoms in a bond, whether the 2 atoms represent a simple diatomic molecule, or are part of some larger molecule.

The value \( \text{dist} \) is the current length of the bond. The values \( dx \), \( dy \), and \( dz \) are the xyz components of the distance between the pair of atoms. This value is always the distance from the atom of lower to the one with the higher id.

The value \( \text{engpot} \) is the potential energy for the bond, based on the current separation of the pair of atoms in the bond.

The value \( \text{force} \) is the magnitude of the force acting between the pair of atoms in the bond.

The values \( fx \), \( fy \), and \( fz \) are the xyz components of \( \text{force} \) between the pair of atoms in the bond.

The remaining properties are all computed for motion of the two atoms relative to the center of mass (COM) velocity of the 2 atoms in the bond.

The value \( \text{engvib} \) is the vibrational kinetic energy of the two atoms in the bond, which is simply \( 1/2 m1 v1^2 + 1/2 m2 v2^2 \), where \( v1 \) and \( v2 \) are the magnitude of the velocity of the 2 atoms along the bond direction, after the COM velocity has been subtracted from each.

The value \( \text{engrot} \) is the rotational kinetic energy of the two atoms in the bond, which is simply \( 1/2 m1 v1^2 + 1/2 m2 v2^2 \), where \( v1 \) and \( v2 \) are the magnitude of the velocity of the 2 atoms perpendicular to the bond direction, after the COM velocity has been subtracted from each.

The value \( \text{engtrans} \) is the translational kinetic energy associated with the motion of the COM of the system itself, namely \( 1/2 (m1+m2) Vcm^2 \) where \( Vcm \) = magnitude of the velocity of the COM.

Note that these 3 kinetic energy terms are simply a partitioning of the summed kinetic energy of the 2 atoms themselves. I.e. total KE = \( 1/2 m1 v1^2 + 1/2 m2 v2^2 \) = engvib + engrot + engtrans, where \( v1, v2 \) are the magnitude of the velocities of the 2 atoms, without any adjustment for the COM velocity.

The value \( \text{omega} \) is the magnitude of the angular velocity of the two atoms around their COM position.

The value \( \text{velvib} \) is the magnitude of the relative velocity of the two atoms in the bond towards each other. A negative value means the 2 atoms are moving toward each other; a positive value means they are moving apart.

The value \( v\_name \) can be used together with the \texttt{set} keyword to compute a user-specified function of the bond distance. The \texttt{name} specified for the \( v\_name \) value is the name of an \texttt{equal-style variable} which should evaluate a formula based on a variable which will store the bond distance. This other variable must be an \texttt{internal-style variable} defined in the input script; its initial numeric value can be anything. It must be an internal-style variable, because this command resets its value directly. The \texttt{set} keyword is used to identify the name of this other variable associated with theta.

As an example, these commands can be added to the bench/in.rhodo script to compute the distance^2 of every bond in the system and output the statistics in various ways:
variable d internal 0.0
variable dsq equal v_d*v_d

compute 1 all property/local batom1 batom2 btype
compute 2 all bond/local engpot dist v_dsq set dist d
dump 1 all local 100 tmp.dump c_1[*] c_2[*]
compute 3 all reduce ave c_2[*]
thermo_style custom step temp press c_3[*]
fix 10 all ave/histo 10 10 100 0 6 20 c_2[3] mode vector file tmp.histo

The `dump local` command will output the energy, distance, distance$^2$ for every bond in the system. The `thermo_style` command will print the average of those quantities via the `compute reduce` command with thermo output. And the `fix ave/histo` command will histogram the distance$^2$ values and write them to a file.

The local data stored by this command is generated by looping over all the atoms owned on a processor and their bonds. A bond will only be included if both atoms in the bond are in the specified compute group. Any bonds that have been broken (see the `bond_style` command) by setting their bond type to 0 are not included. Bonds that have been turned off (see the `fix shake` or `delete_bonds` commands) by setting their bond type negative are written into the file, but their energy will be 0.0.

Note that as atoms migrate from processor to processor, there will be no consistent ordering of the entries within the local vector or array from one timestep to the next. The only consistency that is guaranteed is that the ordering on a particular timestep will be the same for local vectors or arrays generated by other compute commands. For example, bond output from the `compute property/local` command can be combined with data from this command and output by the `dump local` command in a consistent way.

Here is an example of how to do this:

```latex
compute 1 all property/local btype batom1 batom2
compute 2 all bond/local dist engpot
dump 1 all local 1000 tmp.dump index c_1[*] c_2[*]
```

### 18.10.4 Output info

This compute calculates a local vector or local array depending on the number of values. The length of the vector or number of rows in the array is the number of bonds. If a single value is specified, a local vector is produced. If two or more values are specified, a local array is produced where the number of columns = the number of values. The vector or array can be accessed by any command that uses local values from a compute as input. See the `Howto output` page for an overview of LAMMPS output options.

The output for `dist` will be in distance `units`. The output for `velvib` will be in velocity `units`. The output for `omega` will be in velocity/distance `units`. The output for `engtrans`, `engvib`, `engrot`, and `engpot` will be in energy `units`. The output for `force` will be in force `units`.

18.11 compute born/matrix command

18.11.1 Syntax

compute ID group-ID born/matrix keyword value ...

- ID, group-ID are documented in compute command
- born/matrix = style name of this compute command
- zero or more keyword/value pairs may be appended
  keyword = numdiff
  numdiff values = delta virial-ID
  delta = magnitude of strain (dimensionless)
  virial-ID = ID of pressure compute for virial (string)

18.11.2 Examples

compute 1 all born/matrix
compute 1 all born/matrix bond angle
compute 1 all born/matrix numdiff 1.0e-4 myvirial

18.11.3 Description

Define a compute that calculates $\frac{\partial^2 U}{\partial \varepsilon_i \partial \varepsilon_j}$, the second derivatives of the potential energy $U$ w.r.t. strain tensor $\varepsilon$ elements. These values are related to:

$$C^{B}_{i,j} = \frac{1}{V} \frac{\partial^2 U}{\partial \varepsilon_i \partial \varepsilon_j}$$

also called the Born term of elastic constants in the stress-stress fluctuation formalism. This quantity can be used to compute the elastic constant tensor. Using the symmetric Voigt notation, the elastic constant tensor can be written as a 6x6 symmetric matrix:

$$C_{i,j} = \langle C^{B}_{i,j} \rangle + \frac{V}{k_B T} \left( \langle \sigma_i \sigma_j \rangle - \langle \sigma_i \rangle \langle \sigma_j \rangle \right) + \frac{N k_B T}{V} \left( \delta_{i,j} + (\delta_{1,i} + \delta_{2,i} + \delta_{3,i}) \ast (\delta_{1,j} + \delta_{2,j} + \delta_{3,j}) \right)$$
In the above expression, $\sigma$ stands for the virial stress tensor, $\delta$ is the Kronecker delta and the usual notation apply for the number of particle, the temperature and volume respectively $N$, $T$ and $V$. $k_B$ is the Boltzmann constant.

The Born term is a symmetric $6 \times 6$ matrix, as is the matrix of second derivatives of potential energy w.r.t strain, whose 21 independent elements are output in this order:

\[
\begin{pmatrix}
C_1 & C_7 & C_8 & C_9 & C_{10} & C_{11} \\
C_7 & C_2 & C_{12} & C_{13} & C_{14} & C_{15} \\
C_8 & C_{12} & C_3 & C_{16} & C_{17} & C_{18} \\
C_9 & C_{13} & C_{16} & C_4 & C_{19} & C_{20} \\
C_{10} & C_{14} & C_{17} & C_{19} & C_5 & C_{21} \\
C_{11} & C_{15} & C_{18} & C_{20} & C_{21} & C_6
\end{pmatrix}
\]

in this matrix the indices of $C_k$ value are the corresponding element $k$ in the global vector output by this compute. Each term comes from the sum of the derivatives of every contribution to the potential energy in the system as explained in (VanWorkum).

The output can be accessed using usual LAMMPS routines:

```plaintext
compute 1 all born/matrix
compute 2 all pressure NULL virial
variable S1 equal -c_2[1]
variable S2 equal -c_2[2]
variable S3 equal -c_2[3]
variable S4 equal -c_2[4]
variable S5 equal -c_2[5]
variable S6 equal -c_2[6]
fix 1 all ave/time 1 1 1 v_S1 v_S2 v_S3 v_S4 v_S5 v_S6 c_1[*] file born.out
```

In this example, the file `born.out` will contain the information needed to compute the first and second terms of the elastic constant matrix in a post processing procedure. The other required quantities can be accessed using any other LAMMPS usual method. Several examples of this method are provided in the examples/ELASTIC_T/BORN_MATRIX directory described on the Examples doc page.

NOTE: In the above $C_{i,j}$ computation, the fluctuation term involving the virial stress tensor $\sigma$ is the covariance between each elements. In a solid the stress fluctuations can vary rapidly, while average fluctuations can be slow to converge. A detailed analysis of the convergence rate of all the terms in the elastic tensor is provided in the paper by Clavier et al. (Clavier).

Two different computation methods for the Born matrix are implemented in this compute and are mutually exclusive.

The first one is a direct computation from the analytical formula from the different terms of the potential used for the simulations (VanWorkum). However, the implementation of such derivations must be done for every potential form. This has not been done yet and can be very complicated for complex potentials. At the moment a warning message is displayed for every term that is not supporting the compute at the moment. This method is the default for now.

The second method uses finite differences of energy to numerically approximate the second derivatives (Zhen). This is useful when using interaction styles for which the analytical second derivatives have not been implemented. In this cases, the compute applies linear strain fields of magnitude $\delta$ to all the atoms relative to a point at the center of the box. The strain fields are in six different directions, corresponding to the six Cartesian components of the stress tensor defined by LAMMPS. For each direction it applies the strain field in both the positive and negative senses, and the new stress virial tensor of the entire system is calculated after each. The difference in these two virials divided by two times $\delta$, approximates the corresponding components of the second derivative, after applying a suitable unit conversion.

**Note:** It is important to choose a suitable value for $\delta$, the magnitude of strains that are used to generate finite difference approximations to the exact virial stress. For typical systems, a value in the range of 1 part in $10^5$ to $10^6$ will
be sufficient. However, the best value will depend on a multitude of factors including the stiffness of the interatomic potential, the thermodynamic state of the material being probed, and so on. The only way to be sure that you have made a good choice is to do a sensitivity study on a representative atomic configuration, sweeping over a wide range of values of delta. If delta is too small, the output values will vary erratically due to truncation effects. If delta is increased beyond a certain point, the output values will start to vary smoothly with delta, due to growing contributions from higher order derivatives. In between these two limits, the numerical virial values should be largely independent of delta.

The keyword requires the additional arguments `delta` and `virial-ID`. `delta` gives the size of the applied strains. `virial-ID` gives the ID string of the pressure compute that provides the virial stress tensor, requiring that it use the virial keyword e.g.

```latex
compute myvirial all pressure NULL virial
compute 1 all born/matrix numdiff 1.0e-4 myvirial
```

**Output info:**

This compute calculates a global vector with 21 values that are the second derivatives of the potential energy w.r.t. strain. The values are in energy units. The values are ordered as explained above. These values can be used by any command that uses global values from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

The array values calculated by this compute are all “extensive”.

### 18.11.4 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the `Build package` page for more info. LAMMPS was built with that package. See the `Build package` page for more info.

The Born term can be decomposed as a product of two terms. The first one is a general term which depends on the configuration. The second one is specific to every interaction composing your force field (non-bonded, bonds, angle...). Currently not all LAMMPS interaction styles implement the `born_matrix` method giving first and second order derivatives and LAMMPS will exit with an error if this compute is used with such interactions unless the `numdiff` option is also used. The `numdiff` option cannot be used with any other keyword. In this situation, LAMMPS will also exit with an error.

### 18.11.5 Default

18.12 compute centro/atom command

18.12.1 Syntax

```plaintext
compute ID group-ID centro/atom lattice keyword value ...
```

- ID, group-ID are documented in `compute` command centro/atom = style name of this compute command lattice
  - `fcc` or `bcc` or `N` = # of neighbors per atom to include
- zero or more keyword/value pairs may be appended
- keyword = `axes`
  - `axes value = no` or `yes`
    - `no` = do not calculate 3 symmetry axes
    - `yes` = calculate 3 symmetry axes

18.12.2 Examples

```plaintext
compute 1 all centro/atom fcc
compute 1 all centro/atom 8
```

18.12.3 Description

Define a computation that calculates the centro-symmetry parameter for each atom in the group, for either FCC or BCC lattices, depending on the choice of the `lattice` argument. In solid-state systems the centro-symmetry parameter is a useful measure of the local lattice disorder around an atom and can be used to characterize whether the atom is part of a perfect lattice, a local defect (e.g. a dislocation or stacking fault), or at a surface.

The value of the centro-symmetry parameter will be 0.0 for atoms not in the specified compute group.

This parameter is computed using the following formula from (Kelchner)

\[
CS = \sum_{i=1}^{N/2} |\vec{R}_i + \vec{R}_{i+N/2}|^2
\]

where the \( N \) nearest neighbors of each atom are identified and \( \vec{R}_i \) and \( \vec{R}_{i+N/2} \) are vectors from the central atom to a particular pair of nearest neighbors. There are \( N(N-1)/2 \) possible neighbor pairs that can contribute to this formula. The quantity in the sum is computed for each, and the \( N/2 \) smallest are used. This will typically be for pairs of atoms in symmetrically opposite positions with respect to the central atom; hence the \( i + N/2 \) notation.

\( N \) is an input parameter, which should be set to correspond to the number of nearest neighbors in the underlying lattice of atoms. If the keyword `fcc` or `bcc` is used, \( N \) is set to 12 and 8 respectively. More generally, \( N \) can be set to a positive, even integer.

For an atom on a lattice site, surrounded by atoms on a perfect lattice, the centro-symmetry parameter will be 0. It will be near 0 for small thermal perturbations of a perfect lattice. If a point defect exists, the symmetry is broken, and the parameter will be a larger positive value. An atom at a surface will have a large positive parameter. If the atom does not have \( N \) neighbors (within the potential cutoff), then its centro-symmetry parameter is set to 0.0.

If the keyword `axes` has the setting `yes`, then this compute also estimates three symmetry axes for each atom’s local neighborhood. The first two of these are the vectors joining the two pairs of neighbor atoms with smallest contributions to the centro-symmetry parameter, i.e. the two most symmetric pairs of atoms. The third vector is normal to the first

1656 Chapter 18. Computes
two by the right-hand rule. All three vectors are normalized to unit length. For FCC crystals, the first two vectors will lie along a \(<110>\) direction, while the third vector will lie along either a \(<100>\) or \(<111>\) direction. For HCP crystals, the first two vectors will lie along \(<100>\) directions, while the third vector will lie along \(<0001>\). This provides a simple way to measure local orientation in HCP structures. In general, the \textit{axes} keyword can be used to estimate the orientation of symmetry axes in the neighborhood of any atom.

Only atoms within the cutoff of the pairwise neighbor list are considered as possible neighbors. Atoms not in the compute group are included in the \(N\) neighbors used in this calculation.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (e.g. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently or to have multiple compute/dump commands, each with a \textit{centro/atom} style.

### 18.12.4 Output info

By default, this compute calculates the centrosymmetry value for each atom as a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the \textit{Howto output} page for an overview of LAMMPS output options.

If the \textit{axes} keyword setting is \textit{yes}, then a per-atom array is calculated. The first column is the centrosymmetry parameter. The next three columns are the \(x\), \(y\), and \(z\) components of the first symmetry axis, followed by the second, and third symmetry axes in columns 5-7 and 8-10.

The centrosymmetry values are unitless values \(\geq 0.0\). Their magnitude depends on the lattice style due to the number of contributing neighbor pairs in the summation in the formula above. And it depends on the local defects surrounding the central atom, as described above. For the \textit{axes yes} case, the vector components are also unitless, since they represent spatial directions.

Here are typical centro-symmetry values, from a nanoindentation simulation into gold (FCC). These were provided by Jon Zimmerman (Sandia):

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bulk lattice</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>Dislocation core</td>
<td>(\sim 1.0)</td>
<td>(0.5) to (1.25)</td>
</tr>
<tr>
<td>Stacking faults</td>
<td>(\sim 5.0)</td>
<td>(4.0) to (6.0)</td>
</tr>
<tr>
<td>Free surface</td>
<td>(\sim 23.0)</td>
<td></td>
</tr>
</tbody>
</table>

These values are \textbf{not} normalized by the square of the lattice parameter. If they were, normalized values would be:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bulk lattice</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>Dislocation core</td>
<td>(\sim 0.06)</td>
<td>(0.03) to (0.075)</td>
</tr>
<tr>
<td>Stacking faults</td>
<td>(\sim 0.3)</td>
<td>(0.24) to (0.36)</td>
</tr>
<tr>
<td>Free surface</td>
<td>(\sim 1.38)</td>
<td></td>
</tr>
</tbody>
</table>

For BCC materials, the values for dislocation cores and free surfaces would be somewhat different, due to their being only 8 neighbors instead of 12.

18.13.3 Description

Define a computation that calculates an integer chunk ID from 1 to $N_{\text{chunk}}$ for each atom in the group. Values of chunk IDs are determined by the style of chunk, which can be based on atom type or molecule ID or spatial binning or a per-atom property or value calculated by another compute, fix, or atom-style variable. Per-atom chunk IDs can be used by other computes with “chunk” in their style name, such as compute com/chunk or compute msd/chunk. Or they can be used by the fix ave/chunk command to sum and time average a variety of per-atom properties over the atoms in each chunk. Or they can simply be accessed by any command that uses per-atom values from a compute as input, as discussed on the Howto output doc page.

See the Howto chunk page for an overview of how this compute can be used with a variety of other commands to tabulate properties of a simulation. The page gives several examples of input script commands that can be used to calculate interesting properties.

Conceptually it is important to realize that this compute does two simple things. First, it sets the value of $N_{\text{chunk}}$ the number of chunks, which can be a constant value or change over time. Second, it assigns each atom to a chunk via a chunk ID. Chunk IDs range from 1 to $N_{\text{chunk}}$ inclusive; some chunks may have no atoms assigned to them. Atoms that do not belong to any chunk are assigned a value of 0. Note that the two operations are not always performed together. For example, spatial bins can be setup once (which sets $N_{\text{chunk}}$), and atoms assigned to those bins many times thereafter (setting their chunk IDs).

All other commands in LAMMPS that use chunk IDs assume there are $N_{\text{chunk}}$ number of chunks, and that every atom is assigned to one of those chunks, or not assigned to any chunk.

There are many options for specifying for how and when $N_{\text{chunk}}$ is calculated, and how and when chunk IDs are assigned to atoms. The details depend on the chunk style and its args, as well as optional keyword settings. They can also depend on whether a fix ave/chunk command is using this compute, since that command requires $N_{\text{chunk}}$ to remain static across windows of timesteps it specifies, while it accumulates per-chunk averages.

The details are described below.

The different chunk styles operate as follows. For each style, how it calculates $N_{\text{chunk}}$ and assigns chunk IDs to atoms is explained. Note that using the optional keywords can change both of those actions, as described further below where the keywords are discussed.

The binning styles perform a spatial binning of atoms, and assign an atom the chunk ID corresponding to the bin number it is in. $N_{\text{chunk}}$ is set to the number of bins, which can change if the simulation box size changes. This also depends on the setting of the units keyword; e.g. for reduced units the number of chunks may not change even if the box size does.

The bin/1d, bin/2d, and bin/3d styles define bins as 1d layers (slabs), 2d pencils, or 3d boxes. The dim, origin, and delta settings are specified 1, 2, or 3 times. For 2d or 3d bins, there is no restriction on specifying dim = x before dim = y or z, or dim = y before dim = z. Bins in a particular dim have a bin size in that dimension given by delta. In each dimension, bins are defined relative to a specified origin, which may be the lower/upper edge of the simulation box (in that dimension), or its center point, or a specified coordinate value. Starting at the origin, sufficient bins are created in both directions to completely span the simulation box or the bounds specified by the optional bounds keyword.

For orthogonal simulation boxes, the bins are layers, pencils, or boxes aligned with the xyz coordinate axes. For triclinic (non-orthogonal) simulation boxes, the bin faces are parallel to the tilted faces of the simulation box. See the Howto triclinic page for a discussion of the geometry of triclinic boxes in LAMMPS. As described there, a tilted simulation box has edge vectors a,b,c. In that nomenclature, bins in the x dimension have faces with normals in the “b” cross “c” direction. Bins in y have faces normal to the “a” cross “c” direction. And bins in z have faces normal to the “a” cross “b” direction. Note that in order to define the size and position of these bins in an unambiguous fashion, the units option must be set to reduced when using a triclinic simulation box, as noted below.
The meaning of *origin* and *delta* for triclinic boxes is as follows. Consider a triclinic box with bins that are 1d layers or slabs in the x dimension. No matter how the box is tilted, an *origin* of 0.0 means start layers at the lower “b” cross “c” plane of the simulation box and an *origin* of 1.0 means to start layers at the upper “b” cross “c” face of the box. A *delta* value of 0.1 in *reduced* units means there will be 10 layers from 0.0 to 1.0, regardless of the current size or shape of the simulation box.

The *bin/sphere* style defines a set of spherical shell bins around the origin \((x_{\text{orig}}, y_{\text{orig}}, z_{\text{orig}})\), using \(n_{\text{sbin}}\) bins with radii equally spaced between \(sr_{\text{min}}\) and \(sr_{\text{max}}\). This is effectively a 1d vector of bins. For example, if \(sr_{\text{min}} = 1.0\) and \(sr_{\text{max}} = 10.0\) and \(n_{\text{sbin}} = 9\), then the first bin spans \(1.0 < r < 2.0\), and the last bin spans \(9.0 < r \leq 10.0\). The geometry of the bins is the same whether the simulation box is orthogonal or triclinic; i.e. the spherical shells are not tilted or scaled differently in different dimensions to transform them into ellipsoidal shells.

The *bin/cylinder* style defines bins for a cylinder oriented along the axis \(d_{\text{im}}\) with the axis coordinates in the other two radial dimensions at \((c_1, c_2)\). For \(d_{\text{im}} = x\), \(c_1/c_2 = y/z\); for \(d_{\text{im}} = y\), \(c_1/c_2 = x/z\); for \(d_{\text{im}} = z\), \(c_1/c_2 = x/y\). This is effectively a 2d array of bins. The first dimension is along the cylinder axis, the second dimension is radially outward from the cylinder axis. The bin size and positions along the cylinder axis are specified by the *origin* and *delta* values, the same as for the *bin/1d*, *bin/2d*, and *bin/3d* styles. There are \(nc_{\text{bin}}\) concentric circle bins in the radial direction from the cylinder axis with radii equally spaced between \(cr_{\text{min}}\) and \(cr_{\text{max}}\). For example, if \(cr_{\text{min}} = 1.0\) and \(cr_{\text{max}} = 10.0\) and \(nc_{\text{bin}} = 9\), then the first bin spans \(1.0 < r < 2.0\), and the last bin spans \(9.0 < r \leq 10.0\). The geometry of the bins in the radial dimensions is the same whether the simulation box is orthogonal or triclinic; i.e. the concentric circles are not tilted or scaled differently in the two different dimensions to transform them into ellipses.

Each time this compute is invoked, each atom is mapped to a bin based on its current position. Note that between reneighboring timesteps, atoms can move outside the current simulation box. If the box is periodic (in that dimension) the atom is remapping into the periodic box for purposes of binning. If the box is not periodic, the atom may have moved outside the bounds of all bins. If an atom is not inside any bin, the *discard* keyword is used to determine how a chunk ID is assigned to the atom.

The *type* style uses the atom type as the chunk ID. \(N_{\text{chunk}}\) is set to the number of atom types defined for the simulation, e.g. via the *create_box* or *read_data* commands.

The *molecule* style uses the molecule ID of each atom as its chunk ID. \(N_{\text{chunk}}\) is set to the largest chunk ID. Note that this excludes molecule IDs for atoms which are not in the specified group or optional region.

There is no requirement that all atoms in a particular molecule are assigned the same chunk ID (zero or non-zero), though you probably want that to be the case, if you wish to compute a per-molecule property. LAMMPS will issue a warning if that is not the case, but only the first time that \(N_{\text{chunk}}\) is calculated.

Note that atoms with a molecule ID = 0, which may be non-molecular solvent atoms, have an out-of-range chunk ID. These atoms are discarded (not assigned to any chunk) or assigned to \(N_{\text{chunk}}\), depending on the value of the *discard* keyword.

The *compute/fix/variable* styles set the chunk ID of each atom based on a quantity calculated and stored by a compute, fix, or variable. In each case, it must be a per-atom quantity. In each case the referenced floating point values are converted to an integer chunk ID as follows. The floating point value is truncated (rounded down) to an integer value. If the integer value is \(\leq 0\), then a chunk ID of 0 is assigned to the atom. If the integer value is \(> 0\), it becomes the chunk ID to the atom. \(N_{\text{chunk}}\) is set to the largest chunk ID. Note that this excludes atoms which are not in the specified group or optional region.

18.13. compute chunk/atom command

1661
If the style begins with “c_”, a compute ID must follow which has been previously defined in the input script. If no bracketed integer is appended, the per-atom vector calculated by the compute is used. If a bracketed integer is appended, the Ith column of the per-atom array calculated by the compute is used. Users can also write code for their own compute styles and add them to LAMMPS.

If the style begins with “f_”, a fix ID must follow which has been previously defined in the input script. If no bracketed integer is appended, the per-atom vector calculated by the fix is used. If a bracketed integer is appended, the Ith column of the per-atom array calculated by the fix is used. Note that some fixes only produce their values on certain timesteps, which must be compatible with the timestep on which this compute accesses the fix, else an error results. Users can also write code for their own fix styles and add them to LAMMPS.

If a value begins with “v_”, a variable name for an atom or atomfile style variable must follow which has been previously defined in the input script. Variables of style atom can reference thermodynamic keywords and various per-atom attributes, or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of generating per-atom quantities to treat as a chunk ID.

Normally, \( N_{\text{chunk}} \) = the number of chunks, is re-calculated every time this fix is invoked, though the value may or may not change. As explained below, the \( n_{\text{chunk}} \) keyword can be set to once which means \( N_{\text{chunk}} \) will never change.

If a fix ave/chunk command uses this compute, it can also turn off the re-calculation of \( N_{\text{chunk}} \) for one or more windows of timesteps. The extent of the windows, during which \( N_{\text{chunk}} \) is held constant, are determined by the \( N_{\text{every}} \), \( N_{\text{repeat}} \), \( N_{\text{freq}} \) values and the ave keyword setting that are used by the fix ave/chunk command.

Specifically, if ave = one, then for each span of \( N_{\text{freq}} \) timesteps, \( N_{\text{chunk}} \) is held constant between the first timestep when averaging is done (within the \( N_{\text{freq}} \)-length window), and the last timestep when averaging is done (multiple of \( N_{\text{freq}} \)). If ave = running or window, then \( N_{\text{chunk}} \) is held constant forever, starting on the first timestep when the fix ave/chunk command invokes this compute.

Note that multiple fix ave/chunk commands can use the same compute chunk/atom compute. However, the time windows they induce for holding \( N_{\text{chunk}} \) constant must be identical, else an error will be generated.

The various optional keywords operate as follows. Note that some of them function differently or are ignored by different chunk styles. Some of them also have different default values, depending on the chunk style, as listed below.

The region keyword applies to all chunk styles. If used, an atom must be in both the specified group and the specified geometric region to be assigned to a chunk.

The \( n_{\text{chunk}} \) keyword applies to all chunk styles. It specifies how often \( N_{\text{chunk}} \) is recalculated, which in turn can affect the chunk IDs assigned to individual atoms.

If \( n_{\text{chunk}} \) is set to once, then \( N_{\text{chunk}} \) is only calculated once, the first time this compute is invoked. If \( n_{\text{chunk}} \) is set to every, then \( N_{\text{chunk}} \) is re-calculated every time the compute is invoked. Note that, as described above, the use of this compute by the fix ave/chunk command can override the every setting.

The default values for \( n_{\text{chunk}} \) are listed below and depend on the chunk style and other system and keyword settings. They attempt to represent typical use cases for the various chunk styles. The \( n_{\text{chunk}} \) value can always be set explicitly if desired.

The limit keyword can be used to limit the calculated value of \( N_{\text{chunk}} \) = the number of chunks. The limit is applied each time \( N_{\text{chunk}} \) is calculated, which also limits the chunk IDs assigned to any atom. The limit keyword is used by all chunk styles except the binning styles, which ignore it. This is because the number of bins can be tailored using the bound keyword (described below) which effectively limits the size of \( N_{\text{chunk}} \).
If \(\textit{limit}\) is set to \(\textit{Nc} = 0\), then no limit is imposed on \(\textit{Nchunk}\), though the \textit{compress} keyword can still be used to reduce \(\textit{Nchunk}\), as described below.

If \(\textit{Nc} > 0\), then the effect of the \textit{limit} keyword depends on whether the \textit{compress} keyword is also used with a setting of \textit{yes}, and whether the \textit{compress} keyword is specified before the \textit{limit} keyword or after.

In all cases, \(\textit{Nchunk}\) is first calculated in the usual way for each chunk style, as described above.

First, here is what occurs if \textit{compress yes} is not set. If \textit{limit} is set to \(\textit{Nc max}\), then \(\textit{Nchunk}\) is reset to the smaller of \(\textit{Nchunk}\) and \(\textit{Nc}\). If \textit{limit} is set to \(\textit{Nc exact}\), then \(\textit{Nchunk}\) is reset to \(\textit{Nc}\), whether the original \(\textit{Nchunk}\) was larger or smaller than \(\textit{Nc}\). If \(\textit{Nchunk}\) shrank due to the \textit{limit} setting, then atom chunk IDs > \(\textit{Nchunk}\) will be reset to 0 or \(\textit{Nchunk}\), depending on the setting of the \textit{discard} keyword. If \(\textit{Nchunk}\) grew, there will simply be some chunks with no atoms assigned to them.

If \textit{compress yes} is set, and the \textit{compress} keyword comes before the \textit{limit} keyword, the compression operation is performed first, as described below, which resets \(\textit{Nchunk}\). The \textit{limit} keyword is then applied to the new \(\textit{Nchunk}\) value, exactly as described in the preceding paragraph. Note that in this case, all atoms will end up with chunk IDs \(< \textit{Nc}\), but their original values (e.g. molecule ID or compute/fix/variable) may have been \(> \textit{Nc}\), because of the compression operation.

If \textit{compress yes} is set, and the \textit{compress} keyword comes after the \textit{limit} keyword, then the \textit{limit} value of \(\textit{Nc}\) is applied first to the uncompressed value of \(\textit{Nchunk}\), but only if \(\textit{Nc} < \textit{Nchunk}\) (whether \(\textit{Nc max}\) or \(\textit{Nc exact}\) is used). This effectively means all atoms with chunk IDs \(> \textit{Nchunk}\) have their chunk IDs reset to 0 or \(\textit{Nc}\), depending on the setting of the \textit{discard} keyword. The compression operation is then performed, which may shrink \(\textit{Nchunk}\) further. If the new \(\textit{Nchunk} < \textit{Nc}\) and \textit{limit} = \(\textit{Nc exact}\) is specified, then \(\textit{Nchunk}\) is reset to \(\textit{Nc}\), which results in extra chunks with no atoms assigned to them. Note that in this case, all atoms will end up with chunk IDs \(< \textit{Nc}\, and their original values (e.g. molecule ID or compute/fix/variable value) will also have been \(\leq \textit{Nc}\).

The \textit{ids} keyword applies to all chunk styles. If the setting is \textit{once} then the chunk IDs assigned to atoms the first time this compute is invoked will be permanent, and never be re-computed.

If the setting is \textit{nfreq} and if a \textit{fix ave/chunk} command is using this compute, then in each of the \(\textit{Nchunk} = \text{constant time windows}\) (discussed above), the chunk ID’s assigned to atoms on the first step of the time window will persist until the end of the time window.

If the setting is \textit{every}, which is the default, then chunk IDs are re-calculated on any timestep this compute is invoked.

\textbf{Note: } If you want the persistent chunk-IDs calculated by this compute to be continuous when running from a \textit{restart file}, then you should use the same ID for this compute, as in the original run. This is so that the fix this compute creates to store per-atom quantities will also have the same ID, and thus be initialized correctly with chunk IDs from the restart file.

The \textit{compress} keyword applies to all chunk styles and affects how \(\textit{Nchunk}\) is calculated, which in turn affects the chunk IDs assigned to each atom. It is useful for converting a “sparse” set of chunk IDs (with many IDs that have no atoms assigned to them), into a “dense” set of IDs, where every chunk has one or more atoms assigned to it.

Two possible use cases are as follows. If a large simulation box is mostly empty space, then the \textit{binning} style may produce many bins with no atoms. If \textit{compress} is set to \textit{yes}, only bins with atoms will be contribute to \(\textit{Nchunk}\). Likewise, the \textit{molecule} or \textit{compute/fix/variable} styles may produce large \(\textit{Nchunk}\) values. For example, the \textit{compute cluster/atom} command assigns every atom an atom ID for one of the atoms it is clustered with. For a million-atom system with 5 clusters, there would only be 5 unique chunk IDs, but the largest chunk ID might be 1 million, resulting in \(\textit{Nchunk} = 1\) million. If \textit{compress} is set to \textit{yes}, \(\textit{Nchunk}\) will be reset to 5.

If \textit{compress} is set to \textit{no}, which is the default, no compression is done. If it is set to \textit{yes}, all chunk IDs with no atoms are removed from the list of chunk IDs, and the list is sorted. The remaining chunk IDs are renumbered from 1 to \(\textit{Nchunk}\).
where $N_{\text{chunk}}$ is the new length of the list. The chunk IDs assigned to each atom reflect the new renumbering from 1 to $N_{\text{chunk}}$.

The original chunk IDs (before renumbering) can be accessed by the `compute property/chunk` command and its `id` keyword, or by the `fix ave/chunk` command which outputs the original IDs as one of the columns in its global output array. For example, using the “compute cluster/atom” command discussed above, the original 5 unique chunk IDs might be atom IDs (27,4982,58374,857838,1000000). After compression, these will be renumbered to (1,2,3,4,5). The original values (27,...,1000000) can be output to a file by the `fix ave/chunk` command, or by using the `fix ave/time` command in conjunction with the `compute property/chunk` command.

**Note:** The compression operation requires global communication across all processors to share their chunk ID values. It can require large memory on every processor to store them, even after they are compressed, if there are a large number of unique chunk IDs with atoms assigned to them. It uses a STL map to find unique chunk IDs and store them in sorted order. Each time an atom is assigned a compressed chunk ID, it must access the STL map. All of this means that compression can be expensive, both in memory and CPU time. The use of the `limit` keyword in conjunction with the `compress` keyword can affect these costs, depending on which keyword is used first. So use this option with care.

The `discard` keyword applies to all chunk styles. It affects what chunk IDs are assigned to atoms that do not match one of the valid chunk IDs from 1 to $N_{\text{chunk}}$. Note that it does not apply to atoms that are not in the specified group or optionally specified region. Those atoms are always assigned a chunk ID = 0.

If the calculated chunk ID for an atom is not within the range 1 to $N_{\text{chunk}}$ then it is a “discard” atom. Note that $N_{\text{chunk}}$ may have been shrunk by the `limit` keyword. Or the `compress` keyword may have eliminated chunk IDs that were valid before the compression took place, and are now not in the compressed list. Also note that for the `molecule` chunk style, if new molecules are added to the system, their chunk IDs may exceed a previously calculated $N_{\text{chunk}}$. Likewise, evaluation of a compute/fix/variable on a later timestep may return chunk IDs that are invalid for the previously calculated $N_{\text{chunk}}$.

All the chunk styles except the `binning` styles, must use `discard` set to either `yes` or `no`. If `discard` is set to `yes`, which is the default, then every “discard” atom has its chunk ID set to 0. If `discard` is set to `no`, every “discard” atom has its chunk ID set to $N_{\text{chunk}}$. I.e. it becomes part of the last chunk.

The `binning` styles use the `discard` keyword to decide whether to discard atoms outside the spatial domain covered by bins, or to assign them to the bin they are nearest to.

For the `bin/1d`, `bin/2d`, `bin/3d` styles the details are as follows. If `discard` is set to `yes`, an out-of-domain atom will have its chunk ID set to 0. If `discard` is set to `no`, the atom will have its chunk ID set to the first or last bin in that dimension. If `discard` is set to `mixed`, which is the default, it will only have its chunk ID set to the first or last bin if bins extend to the simulation box boundary in that dimension. This is the case if the `bound` keyword settings are `lower` and `upper`, which is the default. If the `bound` keyword settings are numeric values, then the atom will have its chunk ID set to 0 if it is outside the bounds of any bin. Note that in this case, it is possible that the first or last bin extends beyond the numeric `bounds` settings, depending on the specified `origin`. If this is the case, the chunk ID of the atom is only set to 0 if it is outside the first or last bin, not if it is simply outside the numeric `bounds` setting.

For the `bin/sphere` style the details are as follows. If `discard` is set to `yes`, an out-of-domain atom will have its chunk ID set to 0. If `discard` is set to `no` or `mixed`, the atom will have its chunk ID set to the first or last bin, i.e. the innermost or outermost spherical shell. If the distance of the atom from the origin is less than `rmin`, it will be assigned to the first bin. If the distance of the atom from the origin is greater than `rmax`, it will be assigned to the last bin.

For the `bin/cylinder` style the details are as follows. If `discard` is set to `yes`, an out-of-domain atom will have its chunk ID set to 0. If `discard` is set to `no`, the atom will have its chunk ID set to the first or last bin in both the radial and axis dimensions. If `discard` is set to `mixed`, which is the default, the radial dimension is treated the same as for `discard` = `no`. But for the axis dimension, it will only have its chunk ID set to the first or last bin if bins extend to the simulation box boundary in the axis dimension. This is the case if the `bound` keyword settings are `lower` and `upper`, which is the default. If the `bound` keyword settings are numeric values, then the atom will have its chunk ID set to 0 if it is outside
the bounds of any bin. Note that in this case, it is possible that the first or last bin extends beyond the numeric bounds settings, depending on the specified origin. If this is the case, the chunk ID of the atom is only set to 0 if it is outside the first or last bin, not if it is simply outside the numeric bounds setting.

If discard is set to no or mixed, the atom will have its chunk ID set to the first or last bin, i.e. the innermost or outermost spherical shell. If the distance of the atom from the origin is less than rmin, it will be assigned to the first bin. If the distance of the atom from the origin is greater than rmax, it will be assigned to the last bin.

The bound keyword only applies to the bin/1d, bin/2d, bin/3d styles and to the axis dimension of the bin/cylinder style; otherwise it is ignored. It can be used one or more times to limit the extent of bin coverage in a specified dimension, i.e. to only bin a portion of the box. If the lo setting is lower or the hi setting is upper, the bin extent in that direction extends to the box boundary. If a numeric value is used for lo and/or hi, then the bin extent in the lo or hi direction extends only to that value, which is assumed to be inside (or at least near) the simulation box boundaries, though LAMMPS does not check for this. Note that using the bound keyword typically reduces the total number of bins and thus the number of chunks Nchunk.

The pbc keyword only applies to the bin/sphere and bin/cylinder styles. If set to yes, the distance an atom is from the sphere origin or cylinder axis is calculated in a minimum image sense with respect to periodic dimensions, when determining which bin the atom is in. I.e. if x is a periodic dimension and the distance between the atom and the sphere center in the x dimension is greater than 0.5 * simulation box length in x, then a box length is subtracted to give a distance < 0.5 * simulation box length. This allows the sphere or cylinder center to be near a box edge, and atoms on the other side of the periodic box will still be close to the center point/axis. Note that with a setting of yes, the outer sphere or cylinder radius must also be <= 0.5 * simulation box length in any periodic dimension except for the cylinder axis dimension, or an error is generated.

The units keyword only applies to the binning styles; otherwise it is ignored. For the bin/1d, bin/2d, bin/3d styles, it determines the meaning of the distance units used for the bin sizes delta and for origin and bounds values if they are coordinate values. For the bin/sphere style it determines the meaning of the distance units used for xorig,yorig,zorig and the radii srmin and srmax. For the bin/cylinder style it determines the meaning of the distance units used for delta,c1,c2 and the radii crmin and crmax.

For orthogonal simulation boxes, any of the 3 options may be used. For non-orthogonal (triclinic) simulation boxes, only the reduced option may be used.

A box value selects standard distance units as defined by the units command, e.g. Angstroms for units = real or metal. A lattice value means the distance units are in lattice spacings. The lattice command must have been previously used to define the lattice spacing. A reduced value means normalized unitless values between 0 and 1, which represent the lower and upper faces of the simulation box respectively. Thus an origin value of 0.5 means the center of the box in any dimension. A delta value of 0.1 means 10 bins span the box in that dimension.

Note that for the bin/sphere style, the radii srmin and srmax are scaled by the lattice spacing or reduced value of the x dimension.

Note that for the bin/cylinder style, the radii crmin and crmax are scaled by the lattice spacing or reduced value of the first dimension perpendicular to the cylinder axis. E.g. y for an x-axis cylinder, x for a y-axis cylinder, and z for a z-axis cylinder.
18.13.4 Output info

This compute calculates a per-atom vector (the chunk ID), which can be accessed by any command that uses per-atom values from a compute as input. It also calculates a global scalar (the number of chunks), which can be similarly accessed everywhere outside of a per-atom context. See the Howto output page for an overview of LAMMPS output options.

The per-atom vector values are unitless chunk IDs, ranging from 1 to \( N_{\text{chunk}} \) (inclusive) for atoms assigned to chunks, and 0 for atoms not belonging to a chunk. The scalar contains the value of \( N_{\text{chunk}} \).

18.13.5 Restrictions

Even if the \( n_{\text{chunk}} \) keyword is set to once, the chunk IDs assigned to each atom are not stored in a restart files. This means you cannot expect those assignments to persist in a restarted simulation. Instead you must re-specify this command and assign atoms to chunks when the restarted simulation begins.

18.13.6 Related commands

\textit{fix ave/chunk, compute global/atom}

18.13.7 Default

The option defaults are as follows:

- region = none
- \( n_{\text{chunk}} \) = every, if compress is yes, overriding other defaults listed here
- \( n_{\text{chunk}} \) = once, for type style
- \( n_{\text{chunk}} \) = once, for mol style if region is none
- \( n_{\text{chunk}} \) = every, for mol style if region is set
- \( n_{\text{chunk}} \) = once, for binning style if the simulation box size is static or units = reduced
- \( n_{\text{chunk}} \) = every, for binning style if the simulation box size is dynamic and units is lattice or box
- \( n_{\text{chunk}} \) = every, for compute/fix/variable style
- limit = 0
- ids = every
- compress = no
- discard = yes, for all styles except binning
- discard = mixed, for binning styles
- bound = lower and upper in all dimensions
- pbc = no
- units = lattice
18.14 compute chunk/spread/atom command

18.14.1 Syntax

```
compute ID group-ID chunk/spread/atom chunkID input1 input2 ...
```

- ID, group-ID are documented in `compute` command
- chunk/spread/atom = style name of this compute command
- chunkID = ID of `compute chunk/atom` command
- one or more inputs can be listed
- input = c_ID, c_ID[N], f_ID, f_ID[N]

- `c_ID` = global vector calculated by a compute with ID
- `c_ID[I]` = Ith column of global array calculated by a compute with ID, I can include wildcard (see below)
- `f_ID` = global vector calculated by a fix with ID
- `f_ID[I]` = Ith column of global array calculated by a fix with ID, I can include wildcard (see below)

18.14.2 Examples

```
compute 1 all chunk/spread/atom mychunk c_com[*] c_gyration
```

18.14.3 Description

Define a calculation that “spreads” one or more per-chunk values to each atom in the chunk. This can be useful in several scenarios:

- For creating a dump file where each atom lists info about the chunk it is in, e.g., for post-processing purposes.
- To access chunk value in atom-style variables that need info about the chunk each atom is in.
- To use the fix ave/chunk command to spatially average per-chunk values calculated by a per-chunk compute.

Examples are given below.

In LAMMPS, chunks are collections of atoms defined by a `compute chunk/atom` command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the `compute chunk/atom` and `How to chunk` doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

For inputs that are computes, they must be a compute that calculates per-chunk values. These are computes whose style names end in “chunk”.

For inputs that are fixes, they should be a fix that calculates per-chunk values. For example, fix ave/chunk or fix ave/time (assuming it is time-averaging per-chunk data).

For each atom, this compute accesses its chunk ID from the specified chunkID compute, then accesses the per-chunk value in each input. Those values are copied to this compute to become the output for that atom.

The values generated by this compute will be 0.0 for atoms not in the specified compute group group-ID. They will also be 0.0 if the atom is not in a chunk, as assigned by the chunkID compute. They will also be 0.0 if the current chunk ID for the atom is out-of-bounds with respect to the number of chunks stored by a particular input compute or fix.
Note: LAMMPS does not check that a compute or fix which calculates per-chunk values uses the same definition of chunks as this compute. It’s up to you to be consistent. Likewise, for a fix input, LAMMPS does not check that it is per-chunk data. It only checks that the fix produces a global vector or array.

Each listed input is operated on independently.

If a bracketed index I is used, it can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “*n” or “n*” or “m*n”. If N = the number of columns in the array, then an asterisk with no numeric values means all indices from 1 to N. A leading asterisk means all indices from 1 to n (inclusive). A trailing asterisk means all indices from n to N (inclusive). A middle asterisk means all indices from m to n (inclusive).

Using a wildcard is the same as if the individual columns of the array had been listed one by one. E.g. these 2 compute chunk/spread/atom commands are equivalent, since the compute com/chunk command creates a per-atom array with 3 columns:

```plaintext
compute com all com/chunk mychunk
compute 10 all chunk/spread/atom mychunk c_com[*]
```

Here is an example of writing a dump file the with the center-of-mass (COM) for the chunk each atom is in. The commands below can be added to the bench/in.chain script.

```plaintext
compute cmol all chunk/atom molecule
compute com all com/chunk cmol
compute comchunk all chunk/spread/atom cmol c_com[*]
dump 1 all custom 50 tmp.dump id mol type x y z c_comchunk[*]
dump_modify 1 sort id
```

The same per-chunk data for each atom could be used to define per-atom forces for the fix addforce command. In this example the forces act to pull atoms of an extended polymer chain towards its COM in an attractive manner.

```plaintext
compute prop all property/atom xu yu zu
variable k equal 0.1
variable fx atom v_k*(c_comchunk[1]-c_prop[1])
variable fy atom v_k*(c_comchunk[2]-c_prop[2])
variable fz atom v_k*(c_comchunk[3]-c_prop[3])
fix 3 all addforce v_fx v_fy v_fz
```

Note that compute property/atom is used to generate unwrapped coordinates for use in the per-atom force calculation, so that the effect of periodic boundaries is accounted for properly.

Over time this applied force could shrink each polymer chain’s radius of gyration in a polymer mixture simulation. Here is output from the bench/in.chain script. Thermo output is shown for 1000 steps, where the last column is the average radius of gyration over all 320 chains in the 32000 atom system:

```plaintext
compute gyr all gyration/chunk cmol
variable ave equal ave(c_gyr)
thermo_style custom step etotal press v_ave
```

(continues on next page)
Here is an example for using one set of chunks, defined for molecules, to compute the dipole moment vector for each chunk. E.g. for water molecules. Then spreading those values to each atom in each chunk. Then defining a second set of chunks based on spatial bins. And finally, using the `fix ave/chunk` command to calculate an average dipole moment vector per spatial bin.

</tbody>
</table>

Note that the `fix ave/chunk` command requires per-atom values as input. That is why the compute chunk/spread/atom command is used to assign per-chunk values to each atom in the chunk. If a molecule straddles bin boundaries, each of its atoms contributes in a weighted manner to the average dipole moment of the spatial bin it is in.

**18.14.4 Output info**

This compute calculates a per-atom vector or array, which can be accessed by any command that uses per-atom values from a compute as input. See the `Howto output` page for an overview of LAMMPS output options.

The output is a per-atom vector if a single input value is specified, otherwise a per-atom array is output. The number of columns in the array is the number of inputs provided. The per-atom values for the vector or each column of the array will be in whatever units the corresponding input value is in.

The vector or array values are “intensive”.

18.17 compute aggregate/atom command

18.17.1 Syntax

```
compute ID group-ID cluster/atom cutoff  
compute ID group-ID fragment/atom keyword value ...  
compute ID group-ID aggregate/atom cutoff
```

- ID, group-ID are documented in `compute` command
- `cluster/atom` or `fragment/atom` or `aggregate/atom` = style name of this compute command
- `cutoff` = distance within which to label atoms as part of same cluster (distance units)
- zero or more keyword/value pairs may be appended to `fragment/atom`
- `keyword = single`
  
  `single value = yes` or `no` to treat single atoms (no bonds) as fragments

18.17.2 Examples

```
compute 1 all cluster/atom 3.5  
compute 1 all fragment/atom  
compute 1 all fragment/atom single no  
compute 1 all aggregate/atom 3.5
```

18.17.3 Description

Define a computation that assigns each atom a cluster, fragment, or aggregate ID. Only atoms in the compute group are clustered and assigned cluster IDs. Atoms not in the compute group are assigned an ID = 0.

A cluster is defined as a set of atoms, each of which is within the cutoff distance from one or more other atoms in the cluster. If an atom has no neighbors within the cutoff distance, then it is a 1-atom cluster.

A fragment is similarly defined as a set of atoms, each of which has a bond to another atom in the fragment. Bonds can be defined initially via the `data file` or `create_bonds` commands, or dynamically by fixes which create or break bonds
like **fix bond/react**, **fix bond/create**, **fix bond/swap**, or **fix bond/break**. The cluster ID or fragment ID of every atom in the cluster will be set to the smallest atom ID of any atom in the cluster or fragment, respectively.

For the **fragment/atom** style, the **single** keyword determines whether single atoms (not bonded to another atom) are treated as one-atom fragments or not, based on the **yes** or **no** setting. If the setting is **no** (the default), their fragment IDs are set to 0.

An aggregate is defined by combining the rules for clusters and fragments, i.e. a set of atoms, where each of it is within the cutoff distance from one or more atoms within a fragment that is part of the same cluster. This measure can be used to track molecular assemblies like micelles.

For computes **cluster/atom** and **aggregate/atom** a neighbor list needed to compute cluster IDs is constructed each time the compute is invoked. Thus it can be inefficient to compute/dump this quantity too frequently or to have multiple **cluster/atom** or **aggregate/atom** style computes.

**Note:** If you have a bonded system, then the settings of **special_bonds** command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the **special_bonds** command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses the neighbor list, it also means those pairs will not be included when computing the clusters. This does not apply when using long-range coulomb (**coul/long**, **coul/msm**, **coul/wolf** or similar). One way to get around this would be to set special_bond scaling factors to very tiny numbers that are not exactly zero (e.g. 1.0e-50). Another workaround is to write a dump file, and use the **rerun** command to compute the clusters for snapshots in the dump file. The rerun script can use a **special_bonds** command that includes all pairs in the neighbor list.

**Note:** For the compute **fragment/atom** style, each fragment is identified using the current bond topology. This will not account for bonds broken by the **bond_style quartic** command because it does not perform a full update of the bond topology data structures within LAMMPS.

### 18.17.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The per-atom vector values will be an ID > 0, as explained above.

18.18 compute cna/atom command

18.18.1 Syntax

```
compute ID group-ID cna/atom cutoff
```

- ID, group-ID are documented in `compute` command
- cna/atom = style name of this compute command
- cutoff = cutoff distance for nearest neighbors (distance units)

18.18.2 Examples

```
compute 1 all cna/atom 3.08
```

18.18.3 Description

Define a computation that calculates the CNA (Common Neighbor Analysis) pattern for each atom in the group. In solid-state systems the CNA pattern is a useful measure of the local crystal structure around an atom. The CNA methodology is described in (Faken) and (Tsuzuki).

Currently, there are five kinds of CNA patterns LAMMPS recognizes:

- fcc = 1
- hcp = 2
- bcc = 3
- icosahedral = 4
- unknown = 5

The value of the CNA pattern will be 0 for atoms not in the specified compute group. Note that normally a CNA calculation should only be performed on mono-component systems.

The CNA calculation can be sensitive to the specified cutoff value. You should insure the appropriate nearest neighbors of an atom are found within the cutoff distance for the presumed crystal structure. E.g. 12 nearest neighbor for perfect FCC and HCP crystals, 14 nearest neighbors for perfect BCC crystals. These formulas can be used to obtain a good cutoff distance:

\[
r_{cc}^{fcc} = \frac{1}{2} \left( \frac{\sqrt{2}}{2} + 1 \right) \approx 0.8536 \ a
\]

\[
r_{cc}^{bcc} = \frac{1}{2} (\sqrt{2} + 1) a \approx 1.207 \ a
\]

\[
r_{cc}^{hcp} = \frac{1}{2} \left( 1 + \sqrt{\frac{4 + 2x^2}{3}} \right) a
\]
where $a$ is the lattice constant for the crystal structure concerned and in the HCP case, $x = (c/a) / 1.633$, where 1.633 is the ideal $c/a$ for HCP crystals.

Also note that since the CNA calculation in LAMMPS uses the neighbors of an owned atom to find the nearest neighbors of a ghost atom, the following relation should also be satisfied:

$$r_c + r_s > 2 \times \text{cutoff}$$

where $r_c$ is the cutoff distance of the potential, $r_s$ is the skin distance as specified by the `neighbor` command, and cutoff is the argument used with the compute cna/atom command. LAMMPS will issue a warning if this is not the case.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (e.g. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently or to have multiple compute/dump commands, each with a `cna/atom` style.

### 18.18.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The per-atom vector values will be a number from 0 to 5, as explained above.

- `cutoff` = cutoff distance for nearest neighbors (distance units)
18.19.2 Examples

\textbf{compute} 1 all cnp/atom 3.08

18.19.3 Description

Define a computation that calculates the Common Neighborhood Parameter (CNP) for each atom in the group. In solid-state systems the CNP is a useful measure of the local crystal structure around an atom and can be used to characterize whether the atom is part of a perfect lattice, a local defect (e.g. a dislocation or stacking fault), or at a surface.

The value of the CNP parameter will be 0.0 for atoms not in the specified compute group. Note that normally a CNP calculation should only be performed on single component systems.

This parameter is computed using the following formula from \textit{(Tsuzuki)}

$$Q_i = \frac{1}{n_i} \sum_{j=1}^{n_i} \sum_{k=1}^{n_{ij}} \left| \vec{R}_{ik} + \vec{R}_{jk} \right|^2$$

where the index \(j\) goes over the \(n_i\) nearest neighbors of atom \(i\), and the index \(k\) goes over the \(n_{ij}\) common nearest neighbors between atom \(i\) and atom \(j\). \(\vec{R}_{ik}\) and \(\vec{R}_{jk}\) are the vectors connecting atom \(k\) to atoms \(i\) and \(j\). The quantity in the double sum is computed for each atom.

The CNP calculation is sensitive to the specified cutoff value. You should ensure that the appropriate nearest neighbors of an atom are found within the cutoff distance for the presumed crystal structure. E.g. 12 nearest neighbor for perfect FCC and HCP crystals, 14 nearest neighbors for perfect BCC crystals. These formulas can be used to obtain a good cutoff distance:

$$r_{fcc}^c = \frac{1}{2} \left( \frac{\sqrt{2}}{2} + 1 \right) a \approx 0.8536 a$$

$$r_{bcc}^c = \frac{1}{2} (\sqrt{2} + 1) a \approx 1.207 a$$

$$r_{hcp}^c = \frac{1}{2} \left( 1 + \sqrt{\frac{4 + 2x^2}{3}} \right) a$$

where \(a\) is the lattice constant for the crystal structure concerned and in the HCP case, \(x = (c/a) / 1.633\), where 1.633 is the ideal \(c/a\) for HCP crystals.

Also note that since the CNP calculation in LAMMPS uses the neighbors of an owned atom to find the nearest neighbors of a ghost atom, the following relation should also be satisfied:

$$r_c + r_s > 2 \ast \text{cutoff}$$

where \(r_c\) is the cutoff distance of the potential, \(r_s\) is the skin distance as specified by the \textit{neighbor} command, and cutoff is the argument used with the compute cnp/atom command. LAMMPS will issue a warning if this is not the case.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (e.g. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently or to have multiple compute/dump commands, each with a \textit{cnp/atom} style.
18.19.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The per-atom vector values will be real positive numbers. Some typical CNP values:

<table>

- ID, group-ID are documented in compute command
- com = style name of this compute command
18.20.2 Examples

```plaintext
compute 1 all com
```

18.20.3 Description

Define a computation that calculates the center-of-mass of the group of atoms, including all effects due to atoms passing through periodic boundaries.

A vector of three quantities is calculated by this compute, which are the x,y,z coordinates of the center of mass.

**Note:** The coordinates of an atom contribute to the center-of-mass in “unwrapped” form, by using the image flags associated with each atom. See the `dump custom` command for a discussion of “unwrapped” coordinates. See the Atoms section of the `read_data` command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the `set image` command.

18.20.4 Output info

This compute calculates a global vector of length 3, which can be accessed by indices 1-3 by any command that uses global vector values from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

The vector values are “intensive”. The vector values will be in distance *units*.

18.20.5 Restrictions

none

18.20.6 Related commands

```
compute com/chunk

18.20.7 Default

none

18.21 compute com/chunk command

18.21.1 Syntax

```
compute ID group-ID com/chunk chunkID
```

- ID, group-ID are documented in `compute` command
- `com/chunk` = style name of this compute command
- `chunkID` = ID of `compute chunk/atom` command
18.21.2 Examples

```
compute 1 fluid com/chunk molchunk
```

18.21.3 Description

Define a computation that calculates the center-of-mass for multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a `compute chunk/atom` command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the `compute chunk/atom` and `Howto chunk` doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the x,y,z coordinates of the center-of-mass for each chunk, which includes all effects due to atoms passing through periodic boundaries.

Note that only atoms in the specified group contribute to the calculation. The `compute chunk/atom` command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

**Note:** The coordinates of an atom contribute to the chunk’s center-of-mass in “unwrapped” form, by using the image flags associated with each atom. See the `dump custom` command for a discussion of “unwrapped” coordinates. See the Atoms section of the `read_data` command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the `set image` command.

The simplest way to output the results of the compute com/chunk calculation to a file is to use the `fix ave/time` command, for example:

```
compute ccl all chunk/atom molecule
compute myChunk all com/chunk ccl
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
```

18.21.4 Output info

This compute calculates a global array where the number of rows = the number of chunks $N_{chunk}$ as calculated by the specified `compute chunk/atom` command. The number of columns = 3 for the x,y,z center-of-mass coordinates of each chunk. These values can be accessed by any command that uses global array values from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in distance units.

18.22 compute contact/atom command

18.22.1 Syntax

```
compute ID group-ID contact/atom
```

- ID, group-ID are documented in compute command
- contact/atom = style name of this compute command

18.22.2 Examples

```
compute 1 all contact/atom
```

18.22.3 Description

Define a computation that calculates the number of contacts for each atom in a group.

The contact number is defined for finite-size spherical particles as the number of neighbor atoms which overlap the central particle, meaning that their distance of separation is less than or equal to the sum of the radii of the two particles.

The value of the contact number will be 0.0 for atoms not in the specified compute group.

18.22.4 Output info

This compute calculates a per-atom vector, whose values can be accessed by any command that uses per-atom values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The per-atom vector values will be a number \( \geq 0.0 \), as explained above.
18.22.5 Restrictions

This compute is part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This compute requires that atoms store a radius as defined by the atom_style sphere command.

18.22.6 Related commands

compute coord/atom

18.22.7 Default

none

18.23 compute coord/atom command

Accelerator Variants: coord/atom/kk

18.23.1 Syntax

compute ID group-ID coord/atom cstyle args ...

- ID, group-ID are documented in compute command
- coord/atom = style name of this compute command
- cstyle = cutoff or orientorder
  
  cutoff args = cutoff [group group2-ID] typeN
  cutoff = distance within which to count coordination neighbors (distance units)
  group group2-ID = select group-ID to restrict which atoms to consider for coordination number (optional)
  typeN = atom type for Nth coordination count (see asterisk form below)
  orientorder args = orientorderID threshold
  orientorderID = ID of an orientorder/atom compute
  threshold = minimum value of the product of two "connected" atoms

18.23.2 Examples

```
compute 1 all coord/atom cutoff 2.0
compute 1 all coord/atom cutoff 6.0 1 2
compute 1 all coord/atom cutoff 6.0 2*4 5*8 *
compute 1 solute coord/atom cutoff 2.0 group solvent
compute 1 all coord/atom orientorder 2 0.5
```
18.23.3 Description

This compute performs calculations between neighboring atoms to determine a coordination value. The specific calculation and the meaning of the resulting value depend on the cstyle keyword used.

The cutoff cstyle calculates one or more traditional coordination numbers for each atom. A coordination number is defined as the number of neighbor atoms with specified atom type(s), and optionally within the specified group, that are within the specified cutoff distance from the central atom. The compute group selects only the central atoms; all neighboring atoms, unless selected by type, type range, or group option, are included in the coordination number tally.

The optional group keyword allows to specify from which group atoms contribute to the coordination number. Default setting is group ‘all’.

The typeN keywords allow specification of which atom types contribute to each coordination number. One coordination number is computed for each of the typeN keywords listed. If no typeN keywords are listed, a single coordination number is calculated, which includes atoms of all types (same as the ‘*’ format, see below).

The typeN keywords can be specified in one of two ways. An explicit numeric value can be used, as in the second example above. Or a wild-card asterisk can be used to specify a range of atom types. This takes the form ‘*’ or ‘*n’ or ‘n*’ or ‘m*n’. If N = the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive).

The orientorder cstyle calculates the number of “connected” neighbor atoms J around each central atom I. For this cstyle, connected is defined by the orientational order parameter calculated by the compute orientorder/atom command. This cstyle thus allows one to apply the ten Wolde’s criterion to identify crystal-like atoms in a system, as discussed in ten Wolde.

The ID of the previously specified compute orientorder/atom command is specified as orientorderID. The compute must invoke its components option to calculate components of the Ybar_lm vector for each atoms, as described in its documentation. Note that orientorder/atom compute defines its own criteria for identifying neighboring atoms. If the scalar product \((Ybar_{lm}(i),*Ybar_{lm}(j))\), calculated by the orientorder/atom compute is larger than the specified threshold, then I and J are connected, and the coordination value of I is incremented by one.

For all cstyle settings, all coordination values will be 0.0 for atoms not in the specified compute group.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently.

Note: If you have a bonded system, then the settings of special_bonds command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the special_bonds command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses the neighbor list, it also means those pairs will not be included in the coordination count. One way to get around this, is to write a dump file, and use the rerun command to compute the coordination for snapshots in the dump file. The rerun script can use a special_bonds command that includes all pairs in the neighbor list.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.
See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

### 18.23.4 Output info

For *cstyle* cutoff, this compute can calculate a per-atom vector or array. If single *type1* keyword is specified (or if none are specified), this compute calculates a per-atom vector. If multiple *typeN* keywords are specified, this compute calculates a per-atom array, with N columns.

For *cstyle* orientorder, this compute calculates a per-atom vector.

These values can be accessed by any command that uses per-atom values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

The per-atom vector or array values will be a number >= 0.0, as explained above.

#### 18.24.1 Syntax

```
compute ID group-ID damage/atom
```

- ID, group-ID are documented in *compute* command
- damage/atom = style name of this compute command
18.24.2 Examples

```
compute 1 all damage/atom
```

18.24.3 Description

Define a computation that calculates the per-atom damage for each atom in a group. This is a quantity relevant for Peridynamics models. See this document for an overview of LAMMPS commands for Peridynamics modeling.

The “damage” of a Peridynamics particles is based on the bond breakage between the particle and its neighbors. If all the bonds are broken the particle is considered to be fully damaged.

See the PDLAMMPS user guide for a formal definition of “damage” and more details about Peridynamics as it is implemented in LAMMPS.

This command can be used with all the Peridynamic pair styles.

The damage value will be 0.0 for atoms not in the specified compute group.

18.24.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The per-atom vector values are unitless numbers (damage) \( >= 0.0 \).

18.24.5 Restrictions

This compute is part of the PERI package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

```

- ID, group-ID are documented in `compute` command
- dihedral/local = style name of this compute command
- one or more values may be appended
- value = `phi` or `v_name`
  - `phi` = tabulate dihedral angles
  - `v_name` = equal-style variable with name (see below)
LAMMPS Documentation, Release patch 23Jun2022

- zero or more keyword/args pairs may be appended
- keyword = set

```plaintext
set args = phi name
phi = only currently allowed arg
name = name of variable to set with phi
```

18.26.2 Examples

```plaintext
compute 1 all dihedral/local phi
compute 1 all dihedral/local phi v_cos set phi p
```

18.26.3 Description

Define a computation that calculates properties of individual dihedral interactions. The number of datums generated, aggregated across all processors, equals the number of dihedral angles in the system, modified by the group parameter as explained below.

The value $\phi$ is the dihedral angle, as defined in the diagram on the dihedral_style doc page.

The value $v_{\text{name}}$ can be used together with the set keyword to compute a user-specified function of the dihedral angle $\phi$. The name specified for the $v_{\text{name}}$ value is the name of an equal-style variable which should evaluate a formula based on a variable which will store the angle phi. This other variable must be an internal-style variable defined in the input script; its initial numeric value can be anything. It must be an internal-style variable, because this command resets its value directly. The set keyword is used to identify the name of this other variable associated with $\phi$.

Note that the value of $\phi$ for each angle which stored in the internal variable is in radians, not degrees.

As an example, these commands can be added to the bench/in.rhodo script to compute the cosine and cosine^2 of every dihedral angle in the system and output the statistics in various ways:

```plaintext
variable p internal 0.0
variable cos equal cos(v_p)
variable cossq equal cos(v_p)^2 * cos(v_p)

compute 1 all property/local datom1 datom2 datom3 datom4 dtype
compute 2 all dihedral/local phi v_cos v_cossq set phi p
dump 1 all local 100 tmp.dump c_1[\*] c_2[\*]

compute 3 all reduce ave c_2[\*]
thermo_style custom step temp press c_3[\*]

fix 10 all ave/histo 10 10 100 -1 1 20 c_2[2] mode vector file tmp.histo
```

The dump local command will output the angle, cosine(angle), cosine^2(angle) for every dihedral in the system. The thermo_style command will print the average of those quantities via the compute reduce command with thermo output. And the fix ave/histo command will histogram the cosine(angle) values and write them to a file.

The local data stored by this command is generated by looping over all the atoms owned on a processor and their dihedrals. A dihedral will only be included if all 4 atoms in the dihedral are in the specified compute group.
Note that as atoms migrate from processor to processor, there will be no consistent ordering of the entries within the local vector or array from one timestep to the next. The only consistency that is guaranteed is that the ordering on a particular timestep will be the same for local vectors or arrays generated by other compute commands. For example, dihedral output from the `compute property/local` command can be combined with data from this command and output by the `dump local` command in a consistent way.

Here is an example of how to do this:

```plaintext
compute 1 all property/local dtype datom1 datom2 datom3 datom4
calculate 2 all dihedral/local phi
```

### 18.26.4 Output info

This compute calculates a local vector or local array depending on the number of values. The length of the vector or number of rows in the array is the number of dihedrals. If a single value is specified, a local vector is produced. If two or more values are specified, a local array is produced where the number of columns = the number of values. The vector or array can be accessed by any command that uses local values from a compute as input. See the `Howto output` page for an overview of LAMMPS output options.

The output for `phi` will be in degrees.

### 18.27 compute dilatation/atom command

#### 18.27.1 Syntax

```plaintext
compute ID group-ID dilatation/atom
```

- ID, group-ID are documented in compute command
- dilatation/atom = style name of this compute command
18.27.2 Examples

`compute 1 all dilatation/atom`

18.27.3 Description

Define a computation that calculates the per-atom dilatation for each atom in a group. This is a quantity relevant for Peridynamics models. See this document for an overview of LAMMPS commands for Peridynamics modeling.

For small deformation, dilatation of is the measure of the volumetric strain.

The dilatation “theta” for each peridynamic particle I is calculated as a sum over its neighbors with unbroken bonds, where the contribution of the IJ pair is a function of the change in bond length (versus the initial length in the reference state), the volume fraction of the particles and an influence function. See the PDLAMMPS user guide for a formal definition of dilatation.

This command can only be used with a subset of the Peridynamic pair styles: peri/lps, peri/ves and peri/eps.

The dilatation value will be 0.0 for atoms not in the specified compute group.

18.27.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The per-atom vector values are unitless numbers (theta) >= 0.0.

18.27.5 Restrictions

This compute is part of the PERI package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

18.28 compute dipole command

18.28.1 Syntax

`compute ID group-ID dipole charge-correction`

- ID, group-ID are documented in compute command
- dipole = style name of this compute command
• charge-correction = mass or geometry, use COM or geometric center for charged chunk correction (optional)

18.28.2 Examples

```plaintext
compute 1 fluid dipole
compute dw water dipole geometry
```

18.28.3 Description

Define a computation that calculates the dipole vector and total dipole for a group of atoms.

This compute calculates the x,y,z coordinates of the dipole vector and the total dipole moment for the atoms in the compute group. This includes all effects due to atoms passing through periodic boundaries. For a group with a net charge the resulting dipole is made position independent by subtracting the position vector of the center of mass or geometric center times the net charge from the computed dipole vector. Both per-atom charges and per-atom dipole moments, if present, contribute to the computed dipole.

**Note:** The coordinates of an atom contribute to the dipole in “unwrapped” form, by using the image flags associated with each atom. See the `dump custom` command for a discussion of “unwrapped” coordinates. See the Atoms section of the `read_data` command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the `set image` command.

18.28.4 Output info

This compute calculations a global scalar containing the magnitude of the computed dipole moment and a global vector of length 3 with the dipole vector. See the `Howto output` page for an overview of LAMMPS output options.

The computed values are “intensive”. The array values will be in dipole units, i.e. charge units times distance units.

18.28.5 Restrictions

none

18.28.6 Related commands

`compute dipole/chunk`

18.28.7 Default

Using the center of mass is the default setting for the net charge correction.
18.29 compute dipole/chunk command

18.29.1 Syntax

```
compute ID group-ID dipole/chunk chunkID charge-correction
```

- ID, group-ID are documented in `compute` command
- dipole/chunk = style name of this compute command
- chunkID = ID of `compute chunk/atom` command
- charge-correction = `mass` or `geometry`, use COM or geometric center for charged chunk correction (optional)

18.29.2 Examples

```
compute 1 fluid dipole/chunk molchunk
compute dw water dipole/chunk 1 geometry
```

18.29.3 Description

Define a computation that calculates the dipole vector and total dipole for multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a `compute chunk/atom` command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the `compute chunk/atom` and `Howto chunk` doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the x,y,z coordinates of the dipole vector and the total dipole moment for each chunk, which includes all effects due to atoms passing through periodic boundaries. For chunks with a net charge the resulting dipole is made position independent by subtracting the position vector of the center of mass or geometric center times the net charge from the computed dipole vector. Both per-atom charges and per-atom dipole moments, if present, contribute to the computed dipole.

Note that only atoms in the specified group contribute to the calculation. The `compute chunk/atom` command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

Note: The coordinates of an atom contribute to the chunk’s dipole in “unwrapped” form, by using the image flags associated with each atom. See the `dump custom` command for a discussion of “unwrapped” coordinates. See the Atoms section of the `read_data` command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the `set image` command.

The simplest way to output the results of the compute com/chunk calculation to a file is to use the `fix ave/time` command, for example:

```
compute ccl all chunk/atom molecule
compute myChunk all dipole/chunk ccl
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
```
18.29.4 Output info

This compute calculates a global array where the number of rows = the number of chunks \( N_{\text{chunk}} \) as calculated by the specified compute chunk/atom command. The number of columns = 4 for the x,y,z dipole vector components and the total dipole of each chunk. These values can be accessed by any command that uses global array values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in dipole units, i.e. charge units times distance units.

18.29.5 Restrictions

```
18.30.3 Description

Define a computation that calculates the current displacement of each atom in the group from its original (reference) coordinates, including all effects due to atoms passing through periodic boundaries.

A vector of four quantities per atom is calculated by this compute. The first 3 elements of the vector are the dx,dy,dz displacements. The fourth component is the total displacement, i.e. sqrt(dx*dx + dy*dy + dz*dz).

The displacement of an atom is from its original position at the time the compute command was issued. The value of the displacement will be 0.0 for atoms not in the specified compute group.

Note: Initial coordinates are stored in “unwrapped” form, by using the image flags associated with each atom. See the dump custom command for a discussion of “unwrapped” coordinates. See the Atoms section of the read_data command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the set image command.

Note: If you want the quantities calculated by this compute to be continuous when running from a restart file, then you should use the same ID for this compute, as in the original run. This is so that the fix this compute creates to store per-atom quantities will also have the same ID, and thus be initialized correctly with time=0 atom coordinates from the restart file.

The refresh option can be used in conjunction with the “dump_modify refresh” command to generate incremental dump files.

The definition and motivation of an incremental dump file is as follows. Instead of outputting all atoms at each snapshot (with some associated values), you may only wish to output the subset of atoms with a value that has changed in some way compared to the value the last time that atom was output. In some scenarios this can result in a dramatically smaller dump file. If desired, by post-processing the sequence of snapshots, the values for all atoms at all timesteps can be inferred.

A concrete example using this compute, is a simulation of atom diffusion in a solid, represented as atoms on a lattice. Diffusive hops are rare. Imagine that when a hop occurs an atom moves more than a distance \( D_{hop} \). For any snapshot we only want to output atoms that have hopped since the last snapshot. This can be accomplished with something like the following commands:

```
write_dump          all custom tmp.dump id type x y z      # see comment below
variable            Dhop equal 0.6
variable            check atom "c_dsp[4] > v_Dhop"
compute             dsp all displace/atom refresh check
dump                1 all custom 100 tmp.dump id type x y z
dump_modify         1 append yes thresh c_dsp[4] > ${Dhop} &
                      refresh c_dsp delay 100
```

The dump_modify thresh command will only output atoms that have displaced more than 0.6 Angstroms on each snapshot (assuming metal units). The dump_modify refresh option triggers a call to this compute at the end of every dump.

The refresh argument for this compute is the ID of an atom-style variable which calculates a Boolean value (0 or 1) based on the same criterion used by dump_modify thresh. This compute evaluates the atom-style variable. For each atom that returns 1 (true), the original (reference) coordinates of the atom (stored by this compute) are updated.
The effect of these commands is that a particular atom will only be output in the dump file on the snapshot after it makes a diffusive hop. It will not be output again until it makes another hop.

Note that in the first snapshot of a subsequent run, no atoms will be typically be output. That is because the initial displacement for all atoms is 0.0. If an initial dump snapshot is desired, containing the initial reference positions of all atoms, one way to do this is illustrated above. An initial write_dump command can be used before the first run. It will contain the positions of all the atoms, Options in the dump_modify command above will append new output to that same file and delay the output until a later timestep. The delay setting avoids a second time = 0 snapshot which would be empty.

### 18.30.4 Output info

This compute calculates a per-atom array with 4 columns, which can be accessed by indices 1-4 by any command that uses per-atom values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The per-atom array values will be in distance units.

This compute supports the refresh option as explained above, for use in conjunction with dump_modify refresh to generate incremental dump files.

### 18.30.5 Restrictions

### 18.31 compute dpd command

#### 18.31.1 Syntax

```latex
compute ID group-ID dpd
```

- ID, group-ID are documented in compute command
- dpd = style name of this compute command
18.31.2 Examples

```
compute 1 all dpd
```

18.31.3 Description

Define a computation that accumulates the total internal conductive energy ($U_{\text{cond}}$), the total internal mechanical energy ($U_{\text{mech}}$), the total chemical energy ($U_{\text{chem}}$) and the harmonic average of the internal temperature ($\theta_{\text{avg}}$) for the entire system of particles. See the `compute dpd/atom` command if you want per-particle internal energies and internal temperatures.

The system internal properties are computed according to the following relations:

\[
U_{\text{cond}} = \sum_{i=1}^{N} u_{i}^{\text{cond}} \\
U_{\text{mech}} = \sum_{i=1}^{N} u_{i}^{\text{mech}} \\
U_{\text{chem}} = \sum_{i=1}^{N} u_{i}^{\text{chem}} \\
U = \sum_{i=1}^{N} (u_{i}^{\text{cond}} + u_{i}^{\text{mech}} + u_{i}^{\text{chem}}) \\
\theta_{\text{avg}} = \frac{1}{N} \left( \sum_{i=1}^{N} \frac{1}{\theta_{i}} \right)^{-1}
\]

where $N$ is the number of particles in the system.

18.31.4 Output info

This compute calculates a global vector of length 5 ($U_{\text{cond}}, U_{\text{mech}}, U_{\text{chem}}, \theta_{\text{avg}}, N$), which can be accessed by indices 1-5. See the Howto output page for an overview of LAMMPS output options.

The vector values will be in energy and temperature units.

18.31.5 Restrictions

This command is part of the DPD-REACT package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This command also requires use of the `atom_style dpd` command.

18.32.2 Examples

\[
\text{compute 1 all dpd/atom}
\]

18.32.3 Description

Define a computation that accesses the per-particle internal conductive energy ($u^{\text{cond}}$), internal mechanical energy ($u^{\text{mech}}$), internal chemical energy ($u^{\text{chem}}$) and internal temperatures ($\theta$) for each particle in a group. See the compute dpd command if you want the total internal conductive energy, the total internal mechanical energy, the total chemical energy and average internal temperature of the entire system or group of dpd particles.

18.32.4 Output info

This compute calculates a per-particle array with 4 columns ($u^{\text{cond}}$, $u^{\text{mech}}$, $u^{\text{chem}}$, $\theta$), which can be accessed by indices 1-4 by any command that uses per-particle values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The per-particle array values will be in energy ($u^{\text{cond}}$, $u^{\text{mech}}$, $u^{\text{chem}}$) and temperature ($\theta\text{ units}$).
18.32.5 Restrictions

This command is part of the DPD-REACT package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This command also requires use of the atom_style dpd command.

- efield/atom = style name of this compute command

18.34.2 Examples

```
compute 1 all efield/atom
compute 1 all efield/atom pair yes kspace no
```

Used in input scripts:

```
examples/PACKAGES/dielectric/in.confined
examples/PACKAGES/dielectric/in.nopbc
```
18.34.3 Description

Define a computation that calculates the electric field at each atom in a group. The compute should only enabled with pair and kspace styles that are provided by the DIELECTRIC package because only these styles compute the per-atom electric field at every time step.

The electric field is a 3-component vector. The value of the electric field components will be 0.0 for atoms not in the specified compute group.

The keyword/value option pairs are used in the following ways.

For the pair and kspace keywords, the real-space and reciprocal-space contributions to the electric field can be turned off and on.

18.34.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The per-atom vector values will be in electric field units.

18.34.5 Restrictions

This compute is part of the DIELECTRIC package. It is only enabled if LAMMPS was built with that package.

18.34.6 Related commands

18.34.7 Default

The option defaults are pair = yes and kspace = yes.

18.35 compute entropy/atom command

18.35.1 Syntax

```plaintext
compute ID group-ID entropy/atom sigma cutoff keyword value ...
```

- ID, group-ID are documented in compute command
- entropy/atom = style name of this compute command
- sigma = width of gaussians used in the g(r) smoothing
- cutoff = cutoff for the g(r) calculation
- one or more keyword/value pairs may be appended
keyword = avg or local
avg values = yes or no
cutoff2 = yes
no = do not average the pair entropy over neighbors
cutoff2 = cutoff for the averaging over neighbors
local values = yes or no = use the local density around each atom to normalize the g(r)

18.35.2 Examples

```
compute 1 all entropy/atom 0.25 5.
compute 1 all entropy/atom 0.25 5. avg yes 5.
compute 1 all entropy/atom 0.125 7.3 avg yes 5.1 local yes
```

18.35.3 Description

Define a computation that calculates the pair entropy fingerprint for each atom in the group. The fingerprint is useful to
distinguish between ordered and disordered environments, for instance liquid and solid-like environments, or glassy and
crystalline-like environments. Some applications could be the identification of grain boundaries, a melt-solid interface,
or a solid cluster emerging from the melt. The advantage of this parameter over others is that no a priori information
about the solid structure is required.

This parameter for atom i is computed using the following formula from (Piaggi) and (Nettleton),

\[ s_i^S = -2\pi\rho k_B \int_0^r \left[ g(r) \ln g(r) - g(r) + 1 \right] r^2 dr \]

where \( r \) is a distance, \( g(r) \) is the radial distribution function of atom i and rho is the density of the system. The \( g(r) \)
computed for each atom i can be noisy and therefore it is smoothed using:

\[ g_m^i(r) = \frac{1}{4\pi\rho r^2} \sum_j \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\left(\frac{r-r_{ij}}{\sigma}\right)^2/(2\sigma^2)} \]

where the sum in j goes through the neighbors of atom i, and \( \sigma \) is a parameter to control the smoothing.

The input parameters are sigma the smoothing parameter \( \sigma \), and the cutoff for the calculation of \( g(r) \).

If the keyword avg has the setting yes, then this compute also averages the parameter over the neighbors of atom i
according to:

\[ \langle s_S^k \rangle = \frac{\sum_j s_j^S + s_i^S}{N + 1} \]

where the sum j goes over the neighbors of atom i and N is the number of neighbors. This procedure provides a
sharper distinction between order and disorder environments. In this case the input parameter cutoff2 is the cutoff for
the averaging over the neighbors and must also be specified.

If the avg yes option is used, the effective cutoff of the neighbor list should be cutoff+cutoff2 and therefore it might be
necessary to increase the skin of the neighbor list with:

```
neighbor <skin distance> bin
```

See neighbor for details.

If the local yes option is used, the \( g(r) \) is normalized by the local density around each atom, that is to say the density
around each atom is the number of neighbors within the neighbor list cutoff divided by the corresponding volume. This
option can be useful when dealing with inhomogeneous systems such as those that have surfaces.

18.35. compute entropy/atom command
Here are typical input parameters for fcc aluminum (lattice constant 4.05 Angstroms),

```
compute 1 all entropy/atom 0.25 5.7 avg yes 3.7
```

and for bcc sodium (lattice constant 4.23 Angstroms),

```
compute 1 all entropy/atom 0.25 7.3 avg yes 5.1
```

### 18.35.4 Output info

By default, this compute calculates the pair entropy value for each atom as a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The pair entropy values have units of the Boltzmann constant. They are always negative, and lower values (lower entropy) correspond to more ordered environments.

### 18.35.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

### 18.35.6 Related commands

### 18.36 compute erotate/asphere command

#### 18.36.1 Syntax

```
compute ID group-ID erotate/asphere
```

- ID, group-ID are documented in *compute* command
- erotate/asphere = style name of this compute command
18.36.2 Examples

compute 1 all erotate/asphere

18.36.3 Description

Define a computation that calculates the rotational kinetic energy of a group of aspherical particles. The aspherical particles can be ellipsoids, or line segments, or triangles. See the atom_style and read_data commands for descriptions of these options.

For all 3 types of particles, the rotational kinetic energy is computed as \( \frac{1}{2} w^2 \), where \( I \) is the inertia tensor for the aspherical particle and \( w \) is its angular velocity, which is computed from its angular momentum if needed.

Note: For 2d models, ellipsoidal particles are treated as ellipsoids, not ellipses, meaning their moments of inertia will be the same as in 3d.

18.36.4 Output info

This compute calculates a global scalar (the KE). This value can be used by any command that uses a global scalar value from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “extensive”. The scalar value will be in energy units.

18.36.5 Restrictions

This compute requires that ellipsoidal particles atoms store a shape and quaternion orientation and angular momentum as defined by the atom_style ellipsoid command.

This compute requires that line segment particles atoms store a length and orientation and angular velocity as defined by the atom_style line command.

This compute requires that triangular particles atoms store a size and shape and quaternion orientation and angular momentum as defined by the atom_style tri command.

All particles in the group must be finite-size. They cannot be point particles.

18.37 compute erotate/rigid command

18.37.1 Syntax

```
compute ID group-ID erotate/rigid fix-ID
```

- ID, group-ID are documented in `compute` command
- `erotate/rigid` = style name of this compute command
- `fix-ID` = ID of rigid body fix

18.37.2 Examples

```
compute 1 all erotate/rigid myRigid
```

18.37.3 Description

Define a computation that calculates the rotational kinetic energy of a collection of rigid bodies, as defined by one of the `fix rigid` command variants.

The rotational energy of each rigid body is computed as \( \frac{1}{2} I W_{\text{body}}^2 \), where \( I \) is the inertia tensor for the rigid body, and \( W_{\text{body}} \) is its angular velocity vector. Both \( I \) and \( W_{\text{body}} \) are in the frame of reference of the rigid body, i.e. \( I \) is diagonalized.

The `fix-ID` should be the ID of one of the `fix rigid` commands which defines the rigid bodies. The group specified in the compute command is ignored. The rotational energy of all the rigid bodies defined by the `fix rigid` command is included in the calculation.

18.37.4 Output info

This compute calculates a global scalar (the summed rotational energy of all the rigid bodies). This value can be used by any command that uses a global scalar value from a compute as input. See the `Howto output` page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “extensive”. The scalar value will be in energy units.
18.37.5 Restrictions

This compute is part of the RIGID package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

```

- ID, group-ID are documented in compute command
- erotate/sphere = style name of this compute command

18.38.2 Examples

```
compute 1 all erotate/sphere
```

18.38.3 Description

Define a computation that calculates the rotational kinetic energy of a group of spherical particles.

The rotational energy is computed as $\frac{1}{2} I w^2$, where $I$ is the moment of inertia for a sphere and $w$ is the particle’s angular velocity.

Note: For 2d models, particles are treated as spheres, not disks, meaning their moment of inertia will be the same as in 3d.
18.38.4 Output info

This compute calculates a global scalar (the KE). This value can be used by any command that uses a global scalar value from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “extensive”. The scalar value will be in energy units.

18.38.5 Restrictions

This compute requires that atoms store a radius and angular velocity (omega) as defined by the atom_style sphere command.

All particles in the group must be finite-size spheres or point particles. They cannot be aspherical. Point particles will not contribute to the rotational energy.

18.38.6 Related commands

### 18.40 compute event/displace command

#### 18.40.1 Syntax

```
compute ID group-ID event/displace threshold
```

- ID, group-ID are documented in *compute* command
- event/displace = style name of this compute command
- threshold = minimum distance any particle must move to trigger an event (distance units)

#### 18.40.2 Examples

```
compute 1 all event/displace 0.5
```

#### 18.40.3 Description

Define a computation that flags an “event” if any particle in the group has moved a distance greater than the specified threshold distance when compared to a previously stored reference state (i.e. the previous event). This compute is typically used in conjunction with the *prd* and *tad* commands, to detect if a transition to a new minimum energy basin has occurred.

This value calculated by the compute is equal to 0 if no particle has moved far enough, and equal to 1 if one or more particles have moved further than the threshold distance.
Note: If the system is undergoing significant center-of-mass motion, due to thermal motion, an external force, or an initial net momentum, then this compute will not be able to distinguish that motion from local atom displacements and may generate “false positives.”

18.40.4 Output info

This compute calculates a global scalar (the flag). This value can be used by any command that uses a global scalar value from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The scalar value will be a 0 or 1 as explained above.

18.40.5 Restrictions

This command can only be used if LAMMPS was built with the REPLICA package. See the Build package doc page for more info.

18.41 compute fabric command

18.41.1 Syntax

```
compute ID group-ID fabric cutoff attribute1 attribute2 ... keyword values ...
```

- ID, group-ID are documented in compute command
- fabric = style name of this compute command
- cutoff = type or radius
  - type = cutoffs determined based on atom types
  - radius = cutoffs determined based on atom diameters (atom style sphere)
- one or more attributes may be appended
  - contact = contact tensor
  - branch = branch tensor
  - force/normal = normal force tensor
  - force/tangential = tangential force tensor
- zero or more keyword/value pairs may be appended
- keyword = type/include
type/include value = arg1 arg2
arg = separate lists of types (see below)

18.41.2 Examples

compute 1 all fabric type contact force/normal type/include 1,2 3*4
compute 1 all fabric radius force/normal force/tangential

18.41.3 Description

Define a compute that calculates various fabric tensors for pairwise interaction (Ouadfel). Fabric tensors are commonly used to quantify the anisotropy or orientation of granular contacts but can also be used to characterize the direction of pairwise interactions in general systems. The type and radius settings are used to select whether interactions cutoffs are determined by atom types or by the sum of atomic radii (atom style sphere), respectively. Calling this compute is roughly the cost of a pair style invocation as it involves a loop over the neighbor list. If the normal or tangential force tensors are requested, it will be more expensive than a pair style invocation as it will also recalculate all pair forces.

Four fabric tensors are available: the contact, branch, normal force, or tangential force tensor. The contact tensor is calculated as

\[
C_{ab} = \frac{15}{2} (\phi_{ab} - \text{tr}(\phi)\delta_{ab})
\]

where \( a \) and \( b \) are the \( x, y, z \) directions, \( \delta_{ab} \) is the Kronecker delta function, and the tensor \( \phi \) is defined as

\[
\phi_{ab} = \sum_{n=1}^{N_p} \frac{r_a r_b}{r^2}
\]

where \( n \) loops over the \( N_p \) pair interactions in the simulation, \( r_a \) is the \( a \) component of the radial vector between the two pairwise interacting particles, and \( r \) is the magnitude of the radial vector.

The branch tensor is calculated as

\[
B_{ab} = \frac{15}{6\text{tr}(D)}(D_{ab} - \text{tr}(D)\delta_{ab})
\]

where the tensor \( D \) is defined as

\[
D_{ab} = \sum_{n=1}^{N_p} \frac{1}{N_c(r^2 + C_{cd} r_c r_d)} \frac{r_a r_b}{r^2}
\]

where \( N_c \) is the total number of contacts in the system and the subscripts \( c \) and \( d \) indices are summed according to Einstein notation.

The normal force fabric tensor is calculated as

\[
F_{ab}^n = \frac{15}{6\text{tr}(N)}(N_{ab} - \text{tr}(N)\delta_{ab})
\]

where the tensor \( N \) is defined as

\[
N_{ab} = \sum_{n=1}^{N_p} \frac{1}{N_c(r^2 + C_{cd} r_c r_d)} \frac{r_a r_b}{r^2} f_n
\]

and \( f_n \) is the magnitude of the normal, central-body force between the two atoms.
Finally, the tangential force fabric tensor is only defined for pair styles that apply tangential forces to particles, namely granular pair styles. It is calculated as

\[ F_{ab}^{t} = \frac{15}{9\text{tr}(N)}(T_{ab} - \text{tr}(T)\delta_{ab}) \]

where the tensor \( T \) is defined as

\[ T_{ab} = \sum_{n=1}^{N_p} \frac{1}{N_c(r^2 + C_{cd}r_cr_d)} \frac{r_ar_b}{r^2} f_t \]

and \( f_t \) is the magnitude of the tangential force between the two atoms.

The \textit{type/include} keyword filters interactions based on the types of the two atoms. Interactions between two atoms are only included in calculations if the atom types are in the two lists. Each list consists of a series of type ranges separated by commas. The range can be specified as a single numeric value, or a wildcard asterisk can be used to specify a range of values. This takes the form “*n” or “n*” or “n*n” or “m*n”. For example, if \( M \) = the number of atom types, then an asterisk with no numeric values means all types from 1 to \( M \). A leading asterisk means all types from 1 to \( n \) (inclusive). A trailing asterisk means all types from \( n \) to \( M \) (inclusive). A middle asterisk means all types from \( m \) to \( n \) (inclusive). Multiple \textit{type/include} keywords may be added.

### 18.41.4 Output info

This compute calculates a local vector of doubles and a scalar. The vector stores the unique components of the first requested tensor in the order xx, yy, zz, xy, xz, yz followed by the same components for all subsequent tensors. The length of the vector is therefore six times the number of requested tensors. The scalar output is the number of pairwise interactions included in the calculation of the fabric tensor.

### 18.41.5 Restrictions

This fix is part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the \textit{Build package} doc page for more info.

Currently, compute fabric does not support pair styles with many-body interactions. It also does not support models with long-range Coulombic or dispersion forces, i.e. the kspace_style command in LAMMPS. It also does not support the following fixes which add rigid-body constraints: \textit{fix shake}, \textit{fix rattle}, \textit{fix rigid}, \textit{fix rigid/small}. It does not support granular pair styles that extend beyond the contact of atomic radii (e.g. JKR and DMT).

compute 1 all fep 300 atom charge 2 v_delta
```

Example input scripts available: examples/PACKAGES/fep

18.42.3 Description

Apply a perturbation to parameters of the interaction potential and recalculate the pair potential energy without changing the atomic coordinates from those of the reference, unperturbed system. This compute can be used to calculate free energy differences using several methods, such as free-energy perturbation (FEP), finite-difference thermodynamic integration (FDTI) or Bennet’s acceptance ratio method (BAR).

The potential energy of the system is decomposed in three terms: a background term corresponding to interaction sites whose parameters remain constant, a reference term \( U_0 \) corresponding to the initial interactions of the atoms that will
undergo perturbation, and a term $U_1$ corresponding to the final interactions of these atoms:

$$U(\lambda) = U_{bg} + U_1(\lambda) + U_0(\lambda)$$

A coupling parameter $\lambda$ varying from 0 to 1 connects the reference and perturbed systems:

$$\lambda = 0 \implies U = U_{bg} + U_0$$
$$\lambda = 1 \implies U = U_{bg} + U_1$$

It is possible but not necessary that the coupling parameter (or a function thereof) appears as a multiplication factor of the potential energy. Therefore, this compute can apply perturbations to interaction parameters that are not directly proportional to the potential energy (e.g. $\sigma$ in Lennard-Jones potentials).

This command can be combined with fix adapt to perform multistage free-energy perturbation calculations along step-wise alchemical transformations during a simulation run:

$$\Delta^1_0 A = \sum_{i=0}^{n-1} \Delta^\lambda_{i+1} A = -kT \sum_{i=0}^{n-1} \ln \left\langle \exp \left( -\frac{U(\lambda_{i+1}) - U(\lambda_i)}{kT} \right) \right\rangle_{\lambda_i}$$

This compute is suitable for the finite-difference thermodynamic integration (FDTI) method (Mezei), which is based on an evaluation of the numerical derivative of the free energy by a perturbation method using a very small $\delta$:

$$\Delta^1_0 A = \int_{\lambda=0}^{\lambda=1} \left( \frac{\partial A(\lambda)}{\partial \lambda} \right)_\lambda d\lambda \approx \sum_{i=0}^{n-1} w_i \frac{A(\lambda_i + \delta) - A(\lambda_i)}{\delta}$$

where $w_i$ are weights of a numerical quadrature. The fix adapt command can be used to define the stages of $\lambda$ at which the derivative is calculated and averaged.

The compute fep calculates the exponential Boltzmann term and also the potential energy difference $U_1 - U_0$. By choosing a very small perturbation $\delta$ the thermodynamic integration method can be implemented using a numerical evaluation of the derivative of the potential energy with respect to $\lambda$:

$$\Delta^1_0 A = \int_{\lambda=0}^{\lambda=1} \left\langle \frac{\partial U(\lambda)}{\partial \lambda} \right\rangle_{\lambda} d\lambda \approx \sum_{i=0}^{n-1} w_i \left\langle \frac{U(\lambda_i + \delta) - U(\lambda_i)}{\delta} \right\rangle_{\lambda_i}$$

Another technique to calculate free energy differences is the acceptance ratio method (Bennet), which can be implemented by calculating the potential energy differences with $\delta = 1.0$ on both the forward and reverse routes:

$$\left\langle \frac{1}{1 + \exp \left[ \frac{(U_1 - U_0 - \Delta^1_0 A)/kT}{} \right]} \right\rangle_0 = \left\langle \frac{1}{1 + \exp \left[ \frac{(U_0 - U_1 + \Delta^1_0 A)/kT}{} \right]} \right\rangle_1$$

The value of the free energy difference is determined by numerical root finding to establish the equality.

Concerning the choice of how the atomic parameters are perturbed in order to setup an alchemical transformation route, several strategies are available, such as single-topology or double-topology strategies (Pearlman). The latter does not require modification of bond lengths, angles or other internal coordinates.

NOTES: This compute command does not take kinetic energy into account, therefore the masses of the particles should not be modified between the reference and perturbed states, or along the alchemical transformation route. This compute command does not change bond lengths or other internal coordinates (Boresch, Karplus).

The pair attribute enables various parameters of potentials defined by the pair_style and pair_coeff commands to be changed, if the pair style supports it.

The pstyle argument is the name of the pair style. For example, pstyle could be specified as “lj/cut”. The pparam argument is the name of the parameter to change. This is a list of pair styles and parameters that can be used with this compute. See the doc pages for individual pair styles and their energy formulas for the meaning of these parameters.
Note that it is easy to add new potentials and their parameters to this list. All it typically takes is adding an extract() method to the pair_.cpp file associated with the potential.

Similar to the pair_coeff command, I and J can be specified in one of two ways. Explicit numeric values can be used for each, as in the first example above. I <= J is required. LAMMPS sets the coefficients for the symmetric J,I interaction to the same values. A wild-card asterisk can be used in place of or in conjunction with the I,J arguments to set the coefficients for multiple pairs of atom types. This takes the form "*" or "*n" or "n*" or "m*n". If N = the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive). Note that only type pairs with I <= J are considered; if asterisks imply type pairs where J < I, they are ignored.

If pair_style hybrid or hybrid/overlay is being used, then the pstyle will be a sub-style name. You must specify I,J arguments that correspond to type pair values defined (via the pair_coeff command) for that sub-style.

The v_name argument for keyword pair is the name of an equal-style variable which will be evaluated each time this compute is invoked. It should be specified as v_name, where name is the variable name.

The atom attribute enables atom properties to be changed. The aparam argument is the name of the parameter to change. This is the current list of atom parameters that can be used with this compute:

  • charge = charge on particle

The v_name argument for keyword pair is the name of an equal-style variable which will be evaluated each time this compute is invoked. It should be specified as v_name, where name is the variable name.

18.42. compute fep command 1709
The tail keyword controls the calculation of the tail correction to “van der Waals” pair energies beyond the cutoff, if this has been activated via the pair_modify command. If the perturbation is small, the tail contribution to the energy difference between the reference and perturbed systems should be negligible.

If the keyword volume = yes, then the Boltzmann term is multiplied by the volume so that correct ensemble averaging can be performed over trajectories during which the volume fluctuates or changes (Allen and Tildesley):

\[
\Delta_0^1 A = -kT \sum_{i=0}^{n-1} \ln \left( \frac{V \exp \left( \frac{U(\lambda_{i+1}) - U(\lambda_i)}{kT} \right)}{(V)_{\lambda_i}} \right)_{\lambda_i}
\]

18.42.4 Output info

This compute calculates a global vector of length 3 which contains the energy difference \((U_1 - U_0)\) as c_ID[1], the Boltzmann factor \(\exp(- (U_1 - U_0) / kT)\), or \(V \exp(- (U_1 - U_0) / kT)\), as c_ID[2] and the volume of the simulation box \(V\) as c_ID[3]. \(U_1\) is the pair potential energy obtained with the perturbed parameters and \(U_0\) is the pair potential energy obtained with the unperturbed parameters. The energies include kspace terms if these are used in the simulation.

These output results can be used by any command that uses a global scalar or vector from a compute as input. See the Howto output page for an overview of LAMMPS output options. For example, the computed values can be averaged using fix ave/time.

The values calculated by this compute are “extensive”.

18.42.5 Restrictions

This compute is distributed as the FEP package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

18.42.6 Related commands

fix adapt/fep, fix ave/time, pair_style .../soft

18.42.7 Default

The option defaults are tail = no, volume = no.

(Bennet) Bennet, J Comput Phys, 22, 245 (1976)
18.43 compute fep/ta command

18.43.1 Syntax

```
compute ID group-ID fep/ta temp plane scale_factor keyword value ...
```

- ID, group-ID are documented in the `compute` command
- `fep/ta` = name of this compute command
- `temp` = external temperature (as specified for constant-temperature run)
- `plane` = `xy` or `xz` or `yz`
- `scale_factor` = multiplicative factor for change in plane area
- `zero or more keyword/value pairs may be appended`
- `keyword = tail`
  - `tail value = no` or `yes`
    - `no` = ignore tail correction to pair energies (usually small in fep)
    - `yes` = include tail correction to pair energies

18.43.2 Examples

```
compute 1 all fep/ta 298 xy 1.0005
```

18.43.3 Description

Define a computation that calculates the change in the free energy due to a test-area (TA) perturbation (Gloor). The test-area approach can be used to determine the interfacial tension of the system in a single simulation:

\[
\gamma = \lim_{\Delta A \to 0} \left( \frac{\Delta A_{0-1}}{\Delta A} \right)_{N,V,T} = -\frac{kT}{\Delta A} \ln \langle \exp(- (U_1 - U_0)/kT) \rangle_0
\]

During the perturbation, both axes of `plane` are scaled by multiplying \( \sqrt{\text{scale}_{-factor}} \), while the other axis divided by `scale_factor` such that the overall volume of the system is maintained.

The `tail` keyword controls the calculation of the tail correction to “van der Waals” pair energies beyond the cutoff, if this has been activated via the `pair_modify` command. If the perturbation is small, the tail contribution to the energy difference between the reference and perturbed systems should be negligible.

18.43.4 Output info

This compute calculates a global vector of length 3 which contains the energy difference \( (U_1 - U_0) \) as `c_ID[1]`, the Boltzmann factor \( \exp(-(U_1 - U_0)/kT) \), as `c_ID[2]` and the change in the `plane` area \( \Delta A \) as `c_ID[3]`. \( U_1 \) is the potential energy of the perturbed state and \( U_0 \) is the potential energy of the reference state. The energies include kspace terms if these are used in the simulation.

These output results can be used by any command that uses a global scalar or vector from a compute as input. See the `Howto output` page for an overview of LAMMPS output options. For example, the computed values can be averaged using `fix ave/time`.
18.43.5 Restrictions

Constraints, like fix shake, may lead to incorrect values for energy difference.

This compute is distributed as the FEP package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

```

1712 Chapter 18. Computes
18.44.2 Examples

| compute 1 all global/atom c_chunk c_com[*] |

18.44.3 Description

Define a calculation that assigns global values to each atom from vectors or arrays of global values. The specified index parameter is used to determine which global value is assigned to each atom.

The index parameter must reference a per-atom vector or array from a compute or fix or the evaluation of an atom-style variable. Each input value must reference a global vector or array from a compute or fix or the evaluation of a vector-style variable. Details are given below.

The index value for an atom is used as a index I (from 1 to N) into the vector associated with each of the input values. The Ith value from the input vector becomes one output value for that atom. If the atom is not in the specified group, or the index I < 1 or I > M, where M is the actual length of the input vector, then an output value of 0.0 is assigned to the atom.

An example of how this command is useful, is in the context of “chunks” which are static or dynamic subsets of atoms. The compute chunk/atom command assigns unique chunk IDs to each atom. It’s output can be used as the index parameter for this command. Various other computes with “chunk” in their style name, such as compute com/chunk or compute msd/chunk, calculate properties for each chunk. The output of these commands are global vectors or arrays, with one or more values per chunk, and can be used as input values for this command. This command will then assign the global chunk value to each atom in the chunk, producing a per-atom vector or per-atom array as output. The per-atom values can then be output to a dump file or used by any command that uses per-atom values from a compute as input, as discussed on the Howto output doc page.

As a concrete example, these commands will calculate the displacement of each atom from the center-of-mass of the molecule it is in, and dump those values to a dump file. In this case, each molecule is a chunk.

| compute cchl all chunk/atom molecule |
| compute myChunk all com/chunk cchl |
| compute prop all property/atom xu yu zu |
| compute glob all global/atom c_cchl c_myChunk[*] |
| variable dx atom c_prop[1]-c_globe[1] |
| variable dy atom c_prop[2]-c_globe[2] |
| variable dz atom c_prop[3]-c_globe[3] |
| variable dist atom sqrt(v_dx^2+v_dy^2+v_dz^2) |
| dump_modify 1 sort id |

You can add these commands to the bench/in.chain script to see how they work.

Note that for input values from a compute or fix, the bracketed index I can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “*” or “n*” or “n*m” or “m*n”. If N = the size of the vector (for mode = scalar) or the number of columns in the array (for mode = vector), then an asterisk with no numeric values means all indices from 1 to N. A leading asterisk means all indices from 1 to n (inclusive). A trailing asterisk means all indices from n to N (inclusive). A middle asterisk means all indices from m to n (inclusive).

Using a wildcard is the same as if the individual columns of the array had been listed one by one. E.g. these 2 compute global/atom commands are equivalent, since the compute com/chunk command creates a global array with 3 columns:
This section explains the *index* parameter. Note that it must reference per-atom values, as contrasted with the *input* values which must reference global values.

Note that all of these options generate floating point values. When they are used as an index into the specified input vectors, they simply rounded down to convert the value to integer indices. The final values should range from 1 to N (inclusive), since they are used to access values from N-length vectors.

If *index* begins with “c_”, a compute ID must follow which has been previously defined in the input script. The compute must generate per-atom quantities. See the individual *compute* doc page for details. If no bracketed integer is appended, the per-atom vector calculated by the compute is used. If a bracketed integer is appended, the Ith column of the per-atom array calculated by the compute is used. Users can also write code for their own compute styles and *add them to LAMMPS*. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If *index* begins with “f_”, a fix ID must follow which has been previously defined in the input script. The Fix must generate per-atom quantities. See the individual *fix* page for details. Note that some fixes only produce their values on certain timesteps, which must be compatible with when compute global/atom references the values, else an error results. If no bracketed integer is appended, the per-atom vector calculated by the fix is used. If a bracketed integer is appended, the Ith column of the per-atom array calculated by the fix is used. Users can also write code for their own fix style and *add them to LAMMPS*. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If *index* begins with “v_”, a variable name must follow which has been previously defined in the input script. It must be an *atom-style variable*. Atom-style variables can reference thermodynamic keywords and various per-atom attributes, or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of generating per-atom quantities to use as *index*.

This section explains the kinds of *input* values that can be used. Note that inputs reference global values, as contrasted with the *index* parameter which must reference per-atom values.

If a value begins with “c_”, a compute ID must follow which has been previously defined in the input script. The compute must generate a global vector or array. See the individual *compute* doc page for details. If no bracketed integer is appended, the vector calculated by the compute is used. If a bracketed integer is appended, the Ith column of the array calculated by the compute is used. Users can also write code for their own compute styles and *add them to LAMMPS*. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “f_”, a fix ID must follow which has been previously defined in the input script. The fix must generate a global vector or array. See the individual *fix* doc page for details. Note that some fixes only produce their values on certain timesteps, which must be compatible with when compute global/atom references the values, else an error results. If no bracketed integer is appended, the vector calculated by the fix is used. If a bracketed integer is appended, the Ith column of the array calculated by the fix is used. Users can also write code for their own fix style and *add them to LAMMPS*. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “v_”, a variable name must follow which has been previously defined in the input script. It must be a *vector-style variable*. Vector-style variables can reference thermodynamic keywords and various other attributes of atoms, or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of generating a vector of global quantities which the *index* parameter will reference for assignment of global values to atoms.
18.44.4 Output info

If a single input is specified this compute produces a per-atom vector. If multiple inputs are specified, this compute produces a per-atom array values, where the number of columns is equal to the number of inputs specified. These values can be used by any command that uses per-atom vector or array values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The per-atom vector or array values will be in whatever units the corresponding input values are in.

18.45 compute group/group command

18.45.1 Syntax

```
compute ID group-ID group/group group2-ID keyword value ...
```

- ID, group-ID are documented in *compute* command
- group/group = style name of this compute command
- group2-ID = group ID of second (or same) group
- zero or more keyword/value pairs may be appended
- keyword = *pair* or *kspace* or *boundary* or *molecule*
  - *pair* value = yes or no
  - *kspace* value = yes or no
  - *boundary* value = yes or no
  - *molecule* value = off or inter or intra
18.45.2 Examples

```
compute 1 lower group/group upper
compute 1 lower group/group upper kspace yes
compute mine fluid group/group wall
```

18.45.3 Description

Define a computation that calculates the total energy and force interaction between two groups of atoms: the compute group and the specified group2. The two groups can be the same.

If the `pair` keyword is set to `yes`, which is the default, then the interaction energy will include a pair component which is defined as the pairwise energy between all pairs of atoms where one atom in the pair is in the first group and the other is in the second group. Likewise, the interaction force calculated by this compute will include the force on the compute group atoms due to pairwise interactions with atoms in the specified group2.

**Note:** The energies computed by the `pair` keyword do not include tail corrections, even if they are enabled via the `pair_modify` command.

If the `molecule` keyword is set to `inter` or `intra` than an additional check is made based on the molecule IDs of the two atoms in each pair before including their pairwise interaction energy and force. For the `inter` setting, the two atoms must be in different molecules. For the `intra` setting, the two atoms must be in the same molecule.

If the `kspace` keyword is set to `yes`, which is not the default, and if a `kspace_style` is defined, then the interaction energy will include a Kspace component which is the long-range Coulombic energy between all the atoms in the first group and all the atoms in the second group. Likewise, the interaction force calculated by this compute will include the force on the compute group atoms due to long-range Coulombic interactions with atoms in the specified group2.

Normally the long-range Coulombic energy converges only when the net charge of the unit cell is zero. However, one can assume the net charge of the system is neutralized by a uniform background plasma, and a correction to the system energy can be applied to reduce artifacts. For more information see (Bogusz). If the `boundary` keyword is set to `yes`, which is the default, and `kspace` contributions are included, then this energy correction term will be added to the total group-group energy. This correction term does not affect the force calculation and will be zero if one or both of the groups are charge neutral. This energy correction term is the same as that included in the regular Ewald and PPPM routines.

**Note:** The `molecule` setting only affects the group/group contributions calculated by the `pair` keyword. It does not affect the group/group contributions calculated by the `kspace` keyword.

This compute does not calculate any bond or angle or dihedral or improper interactions between atoms in the two groups.

The pairwise contributions to the group-group interactions are calculated by looping over a neighbor list. The Kspace contribution to the group-group interactions require essentially the same amount of work (FFTs, Ewald summation) as computing long-range forces for the entire system. Thus it can be costly to invoke this compute too frequently.

**Note:** If you have a bonded system, then the settings of `special_bonds` command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the `special_bonds` command, and means those pairwise interactions do not appear in the neighbor list. Because this compute uses a neighbor list, it
also means those pairs will not be included in the group/group interaction. This does not apply when using long-
range coulomb interactions (coul/long, coul/msm, coul/wolf) or similar. One way to get around this would be to set special_bond scaling factors to very tiny numbers that are not exactly zero (e.g. 1.0e-50). Another workaround is to write a dump file, and use the rerun command to compute the group/group interactions for snapshots in the dump file. The rerun script can use a special_bonds command that includes all pairs in the neighbor list.

If you desire a breakdown of the interactions into a pairwise and Kspace component, simply invoke the compute twice with the appropriate yes/no settings for the pair and kspace keywords. This is no more costly than using a single compute with both keywords set to yes. The individual contributions can be summed in a variable if desired.

This document describes how the long-range group-group calculations are performed.

### 18.45.4 Output info

This compute calculates a global scalar (the energy) and a global vector of length 3 (force), which can be accessed by indices 1-3. These values can be used by any command that uses global scalar or vector values from a compute as input. See the [How to output page](#) for an overview of LAMMPS output options.

Both the scalar and vector values calculated by this compute are “extensive”. The scalar value will be in energy units. The vector values will be in force units.

### 18.45.5 Restrictions

Not all pair styles can be evaluated in a pairwise mode as required by this compute. For example, 3-body and other many-body potentials, such as Tersoff and Stillinger-Weber cannot be used. EAM potentials will re-use previously computed embedding term contributions, so the computed pairwise forces and energies are based on the whole system and not valid if particles have been moved since.

Not all Kspace styles support the calculation of group/group interactions. The regular ewald and pppm styles do.

### 18.45.6 Related commands

none

### 18.45.7 Default

The option defaults are pair = yes, kspace = no, boundary = yes, molecule = off.

---

18.46 compute gyration command

18.46.1 Syntax

```
compute ID group-ID gyration
```

- ID, group-ID are documented in `compute` command
- gyration = style name of this compute command

18.46.2 Examples

```
compute 1 molecule gyration
```

18.46.3 Description

Define a computation that calculates the radius of gyration \( R_g \) of the group of atoms, including all effects due to atoms passing through periodic boundaries.

\( R_g \) is a measure of the size of the group of atoms, and is computed as the square root of the \( R_g^2 \) value in this formula

\[
R_g^2 = \frac{1}{M} \sum_i m_i (r_i - r_{cm})^2
\]

where \( M \) is the total mass of the group, \( r_{cm} \) is the center-of-mass position of the group, and the sum is over all atoms in the group.

A \( R_g^2 \) tensor, stored as a 6-element vector, is also calculated by this compute. The formula for the components of the tensor is the same as the above formula, except that \( (r_i - r_{cm})^2 \) is replaced by \( (r_i.x - r_{cm.x}) \cdot (r_i.y - r_{cm.y}) \) for the xy component, and so on. The 6 components of the vector are ordered xx, yy, zz, xy, xz, yz. Note that unlike the scalar \( R_g \), each of the 6 values of the tensor is effectively a “squared” value, since the cross-terms may be negative and taking a \( \sqrt{\text{()}} \) would be invalid.

**Note:** The coordinates of an atom contribute to \( R_g \) in “unwrapped” form, by using the image flags associated with each atom. See the `dump custom` command for a discussion of “unwrapped” coordinates. See the Atoms section of the `read_data` command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the `set image` command.

18.46.4 Output info

This compute calculates a global scalar \( (R_g) \) and a global vector of length 6 \( (R_g^2) \) tensor), which can be accessed by indices 1-6. These values can be used by any command that uses a global scalar value or vector values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The scalar and vector values calculated by this compute are “intensive”. The scalar and vector values will be in distance and distance^2 units respectively.

- zero or more keyword/value pairs may be appended
- keyword = tensor
  tensor value = none

18.47.2 Examples

compute 1 molecule gyration/chunk molchunk
compute 2 molecule gyration/chunk molchunk tensor

18.47.3 Description

Define a computation that calculates the radius of gyration Rg for multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a compute chunk/atom command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the compute chunk/atom and Howto chunk doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the radius of gyration Rg for each chunk, which includes all effects due to atoms passing through periodic boundaries.

Rg is a measure of the size of a chunk, and is computed by this formula

\[ R_g^2 = \frac{1}{M} \sum m_i (r_i - r_{cm})^2 \]
where \( M \) is the total mass of the chunk, \( r_{cm} \) is the center-of-mass position of the chunk, and the sum is over all atoms in the chunk.

Note that only atoms in the specified group contribute to the calculation. The `compute chunk/atom` command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

If the `tensor` keyword is specified, then the scalar \( R_g \) value is not calculated, but an \( R_g \) tensor is instead calculated for each chunk. The formula for the components of the tensor is the same as the above formula, except that \((r_i - r_{cm})^2\) is replaced by \((r_i,x - r_{cm,x}) \cdot (r_i,y - r_{cm,y})\) for the xy component, and so on. The 6 components of the tensor are ordered xx, yy, zz, xy, xz, yz.

Note: The coordinates of an atom contribute to \( R_g \) in “unwrapped” form, by using the image flags associated with each atom. See the `dump custom` command for a discussion of “unwrapped” coordinates. See the Atoms section of the `read_data` command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the `set image` command.

The simplest way to output the results of the compute gyration/chunk calculation to a file is to use the `fix ave/time` command, for example:

```
compute cc1 all chunk/atom molecule
compute myChunk all gyration/chunk cc1
fix 1 all ave/time 100 1 100 c_myChunk file tmp.out mode vector
```

### 18.47.4 Output info

This compute calculates a global vector if the `tensor` keyword is not specified and a global array if it is. The length of the vector or number of rows in the array = the number of chunks \( N_{chunk} \) as calculated by the specified `compute chunk/atom` command. If the `tensor` keyword is specified, the global array has 6 columns. The vector or array can be accessed by any command that uses global values from a compute as input. See the `Howto output` page for an overview of LAMMPS output options.

All the vector or array values calculated by this compute are “intensive”. The vector or array values will be in distance units, since they are the square root of values represented by the formula above.

### 18.47.5 Restrictions

18.48.2 Examples

```plaintext
compute 1 molecule gyration/shape pe
```

18.48.3 Description

Define a computation that calculates the eigenvalues of the gyration tensor of a group of atoms and three shape parameters. The computation includes all effects due to atoms passing through periodic boundaries.

The three computed shape parameters are the asphericity, b, the acylindricity, c, and the relative shape anisotropy, k:

\[
\begin{align*}
  c &= l_z - 0.5(l_y + l_x) \\
  b &= l_y - l_x \\
  k &= \frac{3}{2} \frac{l_x^2 + l_y^2 + l_z^2}{(l_x + l_y + l_z)^2} - \frac{1}{2}
\end{align*}
\]

where \(l_x \leq l_y \leq l_z\) are the three eigenvalues of the gyration tensor. A general description of these parameters is provided in (Mattice) while an application to polymer systems can be found in (Theodorou). The asphericity is always non-negative and zero only when the three principal moments are equal. This zero condition is met when the distribution of particles is spherically symmetric (hence the name asphericity) but also whenever the particle distribution is symmetric with respect to the three coordinate axes, e.g., when the particles are distributed uniformly on a cube, tetrahedron or other Platonic solid. The acylindricity is always non-negative and zero only when the two principal moments are equal. This zero condition is met when the distribution of particles is cylindrically symmetric (hence the name, acylindricity), but also whenever the particle distribution is symmetric with respect to the two coordinate axes, e.g., when the particles are distributed uniformly on a regular prism. The relative shape anisotropy is bounded between zero (if all points are spherically symmetric) and one (if all points lie on a line).

Note: The coordinates of an atom contribute to the gyration tensor in “unwrapped” form, by using the image flags associated with each atom. See the dump custom command for a discussion of “unwrapped” coordinates. See the Atoms section of the read_data command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g., to 0) before invoking this compute by using the set image command.
18.48.4 Output info

This compute calculates a global vector of length 6, which can be accessed by indices 1-6. The first three values are the eigenvalues of the gyration tensor followed by the asphericity, the acylindricity and the relative shape anisotropy. The computed values can be used by any command that uses global vector values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The vector values calculated by this compute are “intensive”. The first five vector values will be in distance^2 units while the sixth one is dimensionless.

18.48.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

18.50 compute heat/flux command

18.50.1 Syntax

compute ID group-ID heat/flux ke-ID pe-ID stress-ID

- ID, group-ID are documented in compute command
- heat/flux = style name of this compute command
- ke-ID = ID of a compute that calculates per-atom kinetic energy
- pe-ID = ID of a compute that calculates per-atom potential energy
- stress-ID = ID of a compute that calculates per-atom stress

18.50.2 Examples

compute myFlux all heat/flux myKE myPE myStress

18.50.3 Description

Define a computation that calculates the heat flux vector based on contributions from atoms in the specified group. This can be used by itself to measure the heat flux through a set of atoms (e.g. a region between two thermostatted reservoirs held at different temperatures), or to calculate a thermal conductivity using the equilibrium Green-Kubo formalism.

For other non-equilibrium ways to compute a thermal conductivity, see the Howto kappa doc page. These include use of the fix thermal/conductivity command for the Muller-Plathe method. Or the fix heat command which can add or subtract heat from groups of atoms.

The compute takes three arguments which are IDs of other computes. One calculates per-atom kinetic energy (ke-ID), one calculates per-atom potential energy (pe-ID), and the third calculates per-atom stress (stress-ID).

Note: These other computes should provide values for all the atoms in the group this compute specifies. That means the other computes could use the same group as this compute, or they can just use group “all” (or any group whose atoms are superset of the atoms in this compute’s group). LAMMPS does not check for this.
In case of two-body interactions, the heat flux is defined as:

\[
J = \frac{1}{V} \left[ \sum_i e_i v_i - \sum_i S_i v_i \right]
= \frac{1}{V} \left[ \sum_i e_i v_i + \sum_{i<j} (F_{ij} \cdot v_j) r_{ij} \right]
= \frac{1}{V} \left[ \sum_i e_i v_i + \frac{1}{2} \sum_{i<j} (F_{ij} \cdot (v_i + v_j)) r_{ij} \right]
\]

\(e_i\) in the first term of the equation is the per-atom energy (potential and kinetic). This is calculated by the computes \textit{ke-ID} and \textit{pe-ID}. \(S_i\) in the second term is the per-atom stress tensor calculated by the compute \textit{stress-ID}. See compute \textit{stress/atom} and compute \textit{centroid/stress/atom} for possible definitions of atomic stress \(S_i\) in the case of bonded and many-body interactions. The tensor multiplies \(v_i\) as a 3x3 matrix-vector multiply to yield a vector. Note that as discussed below, the \(1/V\) scaling factor in the equation for \(J\) is NOT included in the calculation performed by these computes; you need to add it for a volume appropriate to the atoms included in the calculation.

**Note:** The \textit{compute pe/atom} and \textit{compute stress/atom} commands have options for which terms to include in their calculation (pair, bond, etc). The heat flux calculation will thus include exactly the same terms. Normally you should use \textit{compute stress/atom virial} or \textit{compute centroid/stress/atom virial} so as not to include a kinetic energy term in the heat flux.

**Warning:** The compute \textit{heat/flux} has been reported to produce unphysical values for angle, dihedral, improper and constraint force contributions when used with \textit{compute stress/atom}, as discussed in \textit{(Surblys2019)}, \textit{(Boone)} and \textit{(Surblys2021)}. You are strongly advised to use \textit{compute centroid/stress/atom}, which has been implemented specifically for such cases.

**Warning:** Due to an implementation detail, the \(y\) and \(z\) components of heat flux from \textit{fix rigid} contribution when computed via \textit{compute stress/atom} are highly unphysical and should not be used.

The Green-Kubo formulas relate the ensemble average of the auto-correlation of the heat flux \(J\) to the thermal conductivity \(\kappa\):

\[
\kappa = \frac{V}{k_BT^2} \int_0^\infty \langle J_x(0)J_x(t) \rangle \, dt = \frac{V}{3k_BT^2} \int_0^\infty \langle J(0) \cdot J(t) \rangle \, dt
\]

The heat flux can be output every so many timesteps (e.g. via the \textit{thermo_style custom} command). Then as a post-processing operation, an auto-correlation can be performed, its integral estimated, and the Green-Kubo formula above evaluated.

The \textit{fix ave/correlate} command can calculate the auto-correlation. The \text{trap()} function in the \textit{variable} command can calculate the integral.

An example LAMMPS input script for solid Ar is appended below. The result should be: average conductivity \(\sim 0.29\) in W/mK.

---

18.50. \textbf{compute heat/flux command}
18.50.4 Output info

This compute calculates a global vector of length 6. The first 3 components are the \( x, y, z \) components of the full heat flux vector, i.e. \( (J_x, J_y, J_z) \). The next 3 components are the \( x, y, z \) components of just the convective portion of the flux, i.e. the first term in the equation for \( J \). Each component can be accessed by indices 1-6. These values can be used by any command that uses global vector values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The vector values calculated by this compute are “extensive”, meaning they scale with the number of atoms in the simulation. They can be divided by the appropriate volume to get a flux, which would then be an “intensive” value, meaning independent of the number of atoms in the simulation. Note that if the compute is “all”, then the appropriate volume to divide by is the simulation box volume. However, if a sub-group is used, it should be the volume containing those atoms.

The vector values will be in energy*velocity units. Once divided by a volume the units will be that of flux, namely energy/area/time units.

18.50. compute heat/flux command
18.51 compute hexorder/atom command

18.51.1 Syntax

```compute ID group-ID hexorder/atom keyword values ...
```

- ID, group-ID are documented in `compute` command
- `hexorder/atom` = style name of this compute command
- one or more keyword/value pairs may be appended
  
  **keyword** = **degree** or **nnn** or **cutoff**
  
  **cutoff** value = distance cutoff
  
  **nnn** value = number of nearest neighbors
  
  **degree** value = degree n of order parameter

18.51.2 Examples

```compute 1 all hexorder/atom
compute 1 all hexorder/atom degree 4 nnn 4 cutoff 1.2
```

18.51.3 Description

Define a computation that calculates $q_n$, the bond-orientational order parameter for each atom in a group. The hexatic ($n = 6$) order parameter was introduced by Nelson and Halperin as a way to detect hexagonal symmetry in two-dimensional systems. For each atom, $q_n$ is a complex number (stored as two real numbers) defined as follows:

$$q_n = \frac{1}{n_{nn}} \sum_{j=1}^{n_{nn}} e^{i\theta(r_{ij})}$$

where the sum is over the $n_{nn}$ nearest neighbors of the central atom. The angle $\theta$ is formed by the bond vector $r_{ij}$ and the $x$ axis. $\theta$ is calculated only using the $x$ and $y$ components, whereas the distance from the central atom is calculated using all three $x$, $y$, and $z$ components of the bond vector. Neighbor atoms not in the group are included in the order parameter of atoms in the group.

The optional keyword **cutoff** defines the distance cutoff used when searching for neighbors. The default value, also the maximum allowable value, is the cutoff specified by the pair style.

The optional keyword **nnn** defines the number of nearest neighbors used to calculate $q_n$. The default value is 6. If the value is NULL, then all neighbors up to the distance cutoff are used.

The optional keyword **degree** sets the degree $n$ of the order parameter. The default value is 6. For a perfect hexagonal lattice with $n_{nn} = 6$, $q_6 = e^{6i\phi}$ for all atoms, where the constant $0 < \phi < \frac{\pi}{3}$ depends only on the orientation of the lattice relative to the $x$ axis. In an isotropic liquid, local neighborhoods may still exhibit weak hexagonal symmetry, but because the orientational correlation decays quickly with distance, the value of $\phi$ will be different for different atoms, and so when $q_6$ is averaged over all the atoms in the system, $|\langle q_6 \rangle| << 1$.

The value of $q_n$ is set to zero for atoms not in the specified compute group, as well as for atoms that have less than $n_{nn}$ neighbors within the distance cutoff.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently.
Note: If you have a bonded system, then the settings of `special_bonds` command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the `special_bonds` command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses the neighbor list, it also means those pairs will not be included in the order parameter. This difficulty can be circumvented by writing a dump file, and using the `rerun` command to compute the order parameter for snapshots in the dump file. The rerun script can use a `special_bonds` command that includes all pairs in the neighbor list.

### 18.51.4 Output info

This compute calculates a per-atom array with 2 columns, giving the real and imaginary parts $q_n$, a complex number restricted to the unit disk of the complex plane i.e. $Re(q_n)^2 + Im(q_n)^2 \leq 1$.

These values can be accessed by any command that uses per-atom values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

### 18.51.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

#### 18.52.1 Syntax

```
compute ID group-ID hma temp-ID keyword ...
```

- ID, group-ID are documented in `compute` command
- `hma` = style name of this compute command
- `temp-ID` = ID of fix that specifies the set temperature during canonical simulation
- `keyword` = `anharmonic u p Pharm cv`

(18.52. compute hma command) 1729
anharmonic = compute will return anharmonic property values
u = compute will return potential energy
p = compute will return pressure. the following keyword must be the difference between the harmonic pressure and lattice pressure as described below
cv = compute will return the heat capacity

18.52.2 Examples

```plaintext
compute 2 all hma 1 u
compute 2 all hma 1 anharmonic u p 0.9
compute 2 all hma 1 u cv
```

18.52.3 Description

Define a computation that calculates the properties of a solid (potential energy, pressure or heat capacity), using the harmonically-mapped averaging (HMA) method. This command yields much higher precision than the equivalent compute commands (compute pe, compute pressure, etc.) commands during a canonical simulation of an atomic crystal. Specifically, near melting HMA can yield averages of a given precision an order of magnitude faster than conventional methods, and this only improves as the temperatures is lowered. This is particularly important for evaluating the free energy by thermodynamic integration, where the low-temperature contributions are the greatest source of statistical uncertainty. Moreover, HMA has other advantages, including smaller potential-truncation effects, finite-size effects, smaller timestep inaccuracy, faster equilibration and shorter decorrelation time.

HMA should not be used if atoms are expected to diffuse. It is also restricted to simulations in the NVT ensemble. While this compute may be used with any potential in LAMMPS, it will provide inaccurate results for potentials that do not go to 0 at the truncation distance; pair_style lj/smooth/linear and Ewald summation should work fine, while pair_style lj/cut will perform poorly unless the potential is shifted (via pair_modify shift) or the cutoff is large. Furthermore, computation of the heat capacity with this compute is restricted to those that implement the single_hessian method in Pair. Implementing single_hessian in additional pair styles is simple. Please contact Andrew Schultz (ajs42 at buffalo.edu) and David Kofke (kofke at buffalo.edu) if your desired pair style does not have this method. This is the list of pair styles that currently implement single_hessian:

- pair_style lj/smooth/linear

In this method, the analytically known harmonic behavior of a crystal is removed from the traditional ensemble averages, which leads to an accurate and precise measurement of the anharmonic contributions without contamination by noise produced by the already-known harmonic behavior. A detailed description of this method can be found in (Moustafa). The potential energy is computed by the formula:

\[
\langle U \rangle_{HMA} = \frac{d}{2}(N-1)k_B T + \left\langle U + \frac{1}{2} F \cdot \Delta r \right\rangle
\]

where \(N\) is the number of atoms in the system, \(k_B\) is Boltzmann’s constant, \(T\) is the temperature, \(d\) is the dimensionality of the system (2 or 3 for 2d/3d), \(F \cdot \Delta r\) is the sum of dot products of the atomic force vectors and displacement (from lattice sites) vectors, and \(U\) is the sum of pair, bond, angle, dihedral, improper, kspace (long-range), and fix energies.

The pressure is computed by the formula:

\[
\langle P \rangle_{HMA} = \Delta \hat{P} + \left\langle P_{\text{vir}} + \frac{\beta \Delta \hat{P} - \rho}{d(N-1)} F \cdot \Delta r \right\rangle
\]

where \(\rho\) is the number density of the system, \(\Delta \hat{P}\) is the difference between the harmonic and lattice pressure, \(P_{\text{vir}}\) is the virial pressure computed as the sum of pair, bond, angle, dihedral, improper, kspace (long-range), and fix contributions to the force on each atom, and \(k_B = 1/k_B T\). Although the method will work for any value of \(\Delta \hat{P}\) specified (use
pressure units), the precision of the resultant pressure is sensitive to \( \Delta \hat{P} \); the precision tends to be best when \( \Delta \hat{P} \) is the actual difference between the lattice pressure and harmonic pressure.

\[
\langle CV \rangle_{HMA} = \frac{d}{2} (N-1) k_B + \frac{1}{k_B T^2} \left( \langle U_{HMA}^2 \rangle - \langle U_{HMA} \rangle^2 \right) + \frac{1}{4 T} \langle F \cdot \Delta r + \Delta r \cdot \Phi \cdot \Delta r \rangle
\]

where \( \Phi \) is the Hessian matrix. The compute hma command computes the full expression for \( CV \) except for the \( \langle U_{HMA}^2 \rangle \) in the variance term, which can be obtained by passing the \( u \) keyword; you must add this extra contribution to the \( CV \) value reported by this compute. The variance term can cause significant round-off error when computing \( CV \). To address this, the anharmonic keyword can be passed and/or the output format can be specified with more digits.

```plaintext
thermo_modify format float '%22.15e'
```

The anharmonic keyword will instruct the compute to return anharmonic properties rather than the full properties, which include lattice, harmonic and anharmonic contributions. When using this keyword, the compute must be first active (it must be included via a thermo_style custom command) while the atoms are still at their lattice sites (before equilibration).

The temp-ID specified with compute hma command should be same as the fix-ID of Nose-Hoover (fix nvt) or Berendsen (fix temp/berendsen) thermostat used for the simulation. While using this command, Langevin thermostat (fix langevin) should be avoided as its extra forces interfere with the HMA implementation.

**Note:** Compute hma command should be used right after the energy minimization, when the atoms are at their lattice sites. The simulation should not be started before this command has been used in the input script.

The following example illustrates the placement of this command in the input script:

```plaintext
min_style cg
minimize 1e-35 1e-15 50000 500000
compute 1 all hma thermostatid u
fix thermostatid all nvt temp 600.0 600.0 100.0
```

**Note:** Compute hma should be used when the atoms of the solid do not diffuse. Diffusion will reduce the precision in the potential energy computation.

**Note:** The fix_modify energy yes command must also be specified if a fix is to contribute potential energy to this command.

An example input script that uses this compute is included in examples/PACKAGES/hma/ along with corresponding LAMMPS output showing that the HMA properties fluctuate less than the corresponding conventional properties.

### 18.52.4 Output info

This compute calculates a global vector that includes the \( n \) properties requested as arguments to the command (the potential energy, pressure and/or heat capacity). The elements of the vector can be accessed by indices 1-\( n \) by any command that uses global vector values as input. See the Howto output page for an overview of LAMMPS output options.

The vector values calculated by this compute are “extensive”. The scalar value will be in energy units.
18.52.5 Restrictions

This compute is part of the EXTRA-COMPUTE package. It is enabled only if LAMMPS was built with that package. See the Build package page for more info.

18.53 compute improper command

18.53.1 Syntax

compute ID group-ID improper

- ID, group-ID are documented in compute command
- improper = style name of this compute command

18.53.2 Examples

compute 1 all improper

18.53.3 Description

Define a computation that extracts the improper energy calculated by each of the improper sub-styles used in the improper_style hybrid command. These values are made accessible for output or further processing by other commands. The group specified for this command is ignored.

This compute is useful when using improper_style hybrid if you want to know the portion of the total energy contributed by one or more of the hybrid sub-styles.
18.53.4 Output info

This compute calculates a global vector of length \( N \) where \( N \) is the number of sub_styles defined by the \textit{improper_style hybrid} command, which can be accessed by indices 1-\( N \). These values can be used by any command that uses global scalar or vector values from a compute as input. See the \textit{Howto output} page for an overview of LAMMPS output options.

The vector values are “extensive” and will be in energy \textit{units}.

18.54 compute improper/local command

18.54.1 Syntax

\begin{verbatim}
compute ID group-ID improper/local value1 value2 ...
\end{verbatim}

- \( \text{ID, group-ID are documented in compute command} \)
- \( \text{improper/local = style name of this compute command} \)
- \( \text{one or more values may be appended} \)
- \( \text{value = chi} \)
  \( \text{chi = tabulate improper angles} \)

18.54.2 Examples

\begin{verbatim}
compute 1 all improper/local chi
\end{verbatim}
18.54.3 Description

Define a computation that calculates properties of individual improper interactions. The number of datums generated, aggregated across all processors, equals the number of impropers in the system, modified by the group parameter as explained below.

The value \( \chi \) is the improper angle, as defined in the doc pages for the individual improper styles listed on improper_style doc page.

The local data stored by this command is generated by looping over all the atoms owned on a processor and their impropers. An improper will only be included if all 4 atoms in the improper are in the specified compute group.

Note that as atoms migrate from processor to processor, there will be no consistent ordering of the entries within the local vector or array from one timestep to the next. The only consistency that is guaranteed is that the ordering on a particular timestep will be the same for local vectors or arrays generated by other compute commands. For example, improper output from the compute property/local command can be combined with data from this command and output by the dump local command in a consistent way.

Here is an example of how to do this:

```plaintext
compute 1 all property/local itype iatom1 iatom2 iatom3 iatom4
compute 2 all improper/local chi
```

18.54.4 Output info

This compute calculates a local vector or local array depending on the number of keywords. The length of the vector or number of rows in the array is the number of impropers. If a single keyword is specified, a local vector is produced. If two or more keywords are specified, a local array is produced where the number of columns = the number of keywords.

The vector or array can be accessed by any command that uses local values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The output for \( \chi \) will be in degrees.

18.55 compute inertia/chunk command

18.55.1 Syntax

```
compute ID group-ID inertia/chunk chunkID
```

- ID, group-ID are documented in `compute` command
- inertia/chunk = style name of this compute command
- chunkID = ID of `compute chunk/atom` command

18.55.2 Examples

```
compute 1 fluid inertia/chunk molchunk
```

18.55.3 Description

Define a computation that calculates the inertia tensor for multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a `compute chunk/atom` command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the `compute chunk/atom` and *How to chunk* doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the 6 components of the symmetric inertia tensor for each chunk, ordered $I_{xx}, I_{yy}, I_{zz}, I_{xy}, I_{yz}, I_{xz}$. The calculation includes all effects due to atoms passing through periodic boundaries.

Note that only atoms in the specified group contribute to the calculation. The `compute chunk/atom` command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

Note: The coordinates of an atom contribute to the chunk’s inertia tensor in “unwrapped” form, by using the image flags associated with each atom. See the `dump custom` command for a discussion of “unwrapped” coordinates. See the Atoms section of the `read_data` command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the `set image` command.

The simplest way to output the results of the compute inertia/chunk calculation to a file is to use the `fix ave/time` command, for example:

```
compute cc1 all chunk/atom molecule
compute myChunk all inertia/chunk cc1
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
```
18.55.4 Output info

This compute calculates a global array where the number of rows = the number of chunks \( N_{\text{chunk}} \) as calculated by the specified \texttt{compute chunk/atom} command. The number of columns = 6 for the 6 components of the inertia tensor for each chunk, ordered as listed above. These values can be accessed by any command that uses global array values from a compute as input. See the \textit{How to output} page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in mass*distance^2 units.

\end{verbatim}

- ID, group-ID are documented in \texttt{compute} command
- \texttt{ke} = style name of this compute command

18.56.2 Examples

\begin{verbatim}
compute 1 all ke
\end{verbatim}

18.56.3 Description

Define a computation that calculates the translational kinetic energy of a group of particles.

The kinetic energy of each particle is computed as \( \frac{1}{2}mv^2 \), where \( m \) and \( v \) are the mass and velocity of the particle.

There is a subtle difference between the quantity calculated by this compute and the kinetic energy calculated by the \texttt{ke} or \texttt{etotal} keyword used in thermodynamic output, as specified by the \texttt{thermo_style} command. For this compute, kinetic energy is “translational” kinetic energy, calculated by the simple formula above. For thermodynamic output, the \texttt{ke} keyword infers kinetic energy from the temperature of the system with \( \frac{1}{2}k_B T \) of energy for each degree of freedom. For the default temperature computation via the \texttt{compute temp} command, these are the same. But different computes that calculate temperature can subtract out different non-thermal components of velocity and/or include different degrees of freedom (translational, rotational, etc).
18.56.4 Output info

This compute calculates a global scalar (the summed KE). This value can be used by any command that uses a global scalar value from a compute as input. See the Howto output doc page for an overview of LAMMPS output options. The scalar value calculated by this compute is “extensive”. The scalar value will be in energy units.

18.58.1 Syntax

Compute ID group-ID ke/atom/eff

• ID, group-ID are documented in compute command
• ke/atom/eff = style name of this compute command

18.58.2 Examples

compute 1 all ke/atom/eff

18.58.3 Description

Define a computation that calculates the per-atom translational (nuclei and electrons) and radial kinetic energy (electron only) in a group. The particles are assumed to be nuclei and electrons modeled with the electronic force field.

The kinetic energy for each nucleus is computed as $\frac{1}{2}mv^2$, where $m$ corresponds to the corresponding nuclear mass, and the kinetic energy for each electron is computed as $\frac{1}{2}(m_e v^2 + \frac{3}{4}m_e s^2)$, where $m_e$ and $v$ correspond to the mass and translational velocity of each electron, and $s$ to its radial velocity, respectively.

There is a subtle difference between the quantity calculated by this compute and the kinetic energy calculated by the ke or etotal keyword used in thermodynamic output, as specified by the thermo_style command. For this compute, kinetic energy is “translational” plus electronic “radial” kinetic energy, calculated by the simple formula above. For thermodynamic output, the ke keyword infers kinetic energy from the temperature of the system with $\frac{1}{2}k_B T$ of energy for each (nuclear-only) degree of freedom in eFF.
Note: The temperature in eFF should be monitored via the `compute temp/eff` command, which can be printed with thermodynamic output by using the `thermo_modify` command, as shown in the following example:

```plaintext
compute effTemp all temp/eff
thermo_style custom step etotal pe ke temp press
thermo_modify temp effTemp
```

The value of the kinetic energy will be 0.0 for atoms (nuclei or electrons) not in the specified compute group.

### 18.58.4 Output info

This compute calculates a scalar quantity for each atom, which can be accessed by any command that uses per-atom computes as input. See the Howto output page for an overview of LAMMPS output options.

The per-atom vector values will be in energy units.

18.59.2 Examples

```
compute 1 all ke/eff
```

18.59.3 Description

Define a computation that calculates the kinetic energy of motion of a group of eFF particles (nuclei and electrons), as modeled with the electronic force field.

The kinetic energy for each nucleus is computed as \( \frac{1}{2}mv^2 \) and the kinetic energy for each electron is computed as \( \frac{1}{2}(m_e v^2 + \frac{3}{2} m_e s^2) \), where \( m \) corresponds to the nuclear mass, \( m_e \) to the electron mass, \( v \) to the translational velocity of each particle, and \( s \) to the radial velocity of the electron, respectively.

There is a subtle difference between the quantity calculated by this compute and the kinetic energy calculated by the \textit{ke} or \textit{etotal} keyword used in thermodynamic output, as specified by the \textit{thermo_style} command. For this compute, kinetic energy is “translational” and “radial” (only for electrons) kinetic energy, calculated by the simple formula above. For thermodynamic output, the \textit{ke} keyword infers kinetic energy from the temperature of the system with \( \frac{1}{2} k_B T \) of energy for each degree of freedom. For the eFF temperature computation via the \textit{compute temp/eff} command, these are the same. But different computes that calculate temperature can subtract out different non-thermal components of velocity and/or include other degrees of freedom.

\textbf{Warning:} The temperature in eFF models should be monitored via the \textit{compute temp/eff} command, which can be printed with thermodynamic output by using the \textit{thermo_modify} command, as shown in the following example:

```
compute effTemp all temp/eff
thermo_style custom step etotal pe ke temp press
thermo_modify temp effTemp
```

See \textit{compute temp/eff}.

18.59.4 Output info

This compute calculates a global scalar (the KE). This value can be used by any command that uses a global scalar value from a compute as input. See the \textit{Howto output} page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “extensive”. The scalar value will be in energy units.

18.62 compute mliap command

18.62.1 Syntax

```
compute ID group-ID mliap ... keyword values ...
```

- ID, group-ID are documented in compute command
- mliap = style name of this compute command
- two or more keyword/value pairs must be appended
- keyword = model or descriptor or gradgradflag
  
  **model values = style**
  
  style = linear or quadratic or mliappy
  
  **descriptor values = style filename**
  
  style = sna
  
  filename = name of file containing descriptor definitions
  
  **gradgradflag value = 0/1**
  
  toggle gradgrad method for force gradient

18.62.2 Examples

```
compute mliap model linear descriptor sna Ta06A.mliap.descriptor
```

18.62.3 Description

Compute style mliap provides a general interface to the gradient of machine-learning interatomic potentials w.r.t. model parameters. It is used primarily for calculating the gradient of energy, force, and stress components w.r.t. model parameters, which is useful when training mliap pair_style models to match target data. It provides separate definitions of the interatomic potential functional form (model) and the geometric quantities that characterize the atomic positions (descriptor). By defining model and descriptor separately, it is possible to use many different models with a given descriptor, or many different descriptors with a given model. Currently, the compute supports just two models, linear and quadratic, and one descriptor, sna, the SNAP descriptor used by pair_style snap, including the linear, quadratic,
and chem variants. Work is currently underway to extend the interface to handle neural network energy models, and it is also straightforward to add new descriptor styles.

The compute mliap command must be followed by two keywords model and descriptor in either order.

The model keyword is followed by the model style (linear, quadratic or mliappy). The mliappy model is only available if LAMMPS is built with the mliappy python module. There are specific installation instructions for that.

The descriptor keyword is followed by a descriptor style, and additional arguments. The compute currently supports two descriptor styles sna and so3, but it is is straightforward to add additional descriptor styles. The SNAP descriptor style sna is the same as that used by pair_style snap, including the linear, quadratic, and chem variants. A single additional argument specifies the descriptor filename containing the parameters and setting used by the SNAP descriptor. The descriptor filename usually ends in the .mliap.descriptor extension. The format of this file is identical to the descriptor file in the pair_style mliap, and is described in detail there.

Note: The number of LAMMPS atom types (and the value of nelems in the model) must match the value of nelems in the descriptor file.

Compute mliap calculates a global array containing gradient information. The number of columns in the array is \( \text{nelems} \times \text{nparams} + 1 \). The first row of the array contain the derivative of potential energy w.r.t. to each parameter and each element. The last six rows of the array contain the corresponding derivatives of the virial stress tensor, listed in Voigt notation: \( pxx, pyy, pzz, pyz, pxz, pxy \). In between the energy and stress rows are the \( 3 \times N \) rows containing the derivatives of the force components. See section below on output for a detailed description of how rows and columns are ordered.

The element in the last column of each row contains the potential energy, force, or stress, according to the row. These quantities correspond to the user-specified reference potential that must be subtracted from the target data when training a model. The potential energy calculation uses the built in compute thermo_pe. The stress calculation uses a compute called mliap_press that is automatically created behind the scenes, according to the following command:

```
compute mliap_press all pressure NULL virial
```

See section below on output for a detailed explanation of the data layout in the global array.

The optional keyword gradgradflag controls how the force gradient is calculated. A value of 1 requires that the model provide the matrix of double gradients of energy w.r.t. both parameters and descriptors. For the linear and quadratic models this matrix is sparse and so is easily calculated and stored. For other models, this matrix may be prohibitively expensive to calculate and store. A value of 0 requires that the descriptor provide the derivative of the descriptors w.r.t. the position of every neighbor atom. This is not optimal for linear and quadratic models, but may be a better choice for more complex models.

Atoms not in the group do not contribute to this compute. Neighbor atoms not in the group do not contribute to this compute. The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently.

Note: If the user-specified reference potentials includes bonded and non-bonded pairwise interactions, then the settings of special_bonds command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the special_bonds command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses the neighbor list, it also means those pairs will not be included in the calculation. The rerun command is not an option here, since the reference potential is required for the last column of the global array. A work-around is to prevent pairwise interactions from being removed by explicitly adding a tiny positive value for every pairwise interaction that would otherwise be set to zero in the special_bonds command.
18.62.4 Output info

Compute mliap evaluates a global array. The columns are arranged into nelems blocks, listed in order of element \( I \). Each block contains one column for each of the nparams model parameters. A final column contains the corresponding energy, force component on an atom, or virial stress component. The rows of the array appear in the following order:

- 1 row: Derivatives of potential energy w.r.t. each parameter of each element.
- 3*N rows: Derivatives of force components. \( x, y, \) and \( z \) components of force on atom \( i \) appearing in consecutive rows. The atoms are sorted based on atom ID.
- 6 rows: Derivatives of virial stress tensor w.r.t. each parameter of each element. The ordering of the rows follows Voigt notation: \( p_{xx}, p_{yy}, p_{zz}, p_{yz}, p_{xz}, p_{xy} \).

These values can be accessed by any command that uses a global array from a compute as input. See the Howto output doc page for an overview of LAMMPS output options. To see how this command can be used within a Python workflow to train machine-learning interatomic potentials, see the examples in FitSNAP.

18.62.5 Restrictions

This compute is part of the ML-IAP package. It is only enabled if LAMMPS was built with that package. In addition, building LAMMPS with the ML-IAP package requires building LAMMPS with the ML-SNAP package. The mliappy model also requires building LAMMPS with the PYTHON package. See the Build package page for more info.

18.64 compute msd command

18.64.1 Syntax

\texttt{compute ID group-ID msd keyword values ...}

- ID, group-ID are documented in \textit{compute} command
- msd = style name of this compute command
- zero or more keyword/value pairs may be appended
- keyword = \texttt{com} or \texttt{average}
  - \texttt{com} value = \texttt{yes} or \texttt{no}
  - \texttt{average} value = \texttt{yes} or \texttt{no}
18.64.2 Examples

```
compute 1 all  msd
compute 1 upper msd com yes average yes
```

18.64.3 Description

Define a computation that calculates the mean-squared displacement (MSD) of the group of atoms, including all effects due to atoms passing through periodic boundaries. For computation of the non-Gaussian parameter of mean-squared displacement, see the `compute msd/nongauss` command.

A vector of four quantities is calculated by this compute. The first 3 elements of the vector are the squared dx,dy,dz displacements, summed and averaged over atoms in the group. The fourth element is the total squared displacement, i.e. \((dx^2 + dy^2 + dz^2)\), summed and averaged over atoms in the group.

The slope of the mean-squared displacement (MSD) versus time is proportional to the diffusion coefficient of the diffusing atoms.

The displacement of an atom is from its reference position. This is normally the original position at the time the compute command was issued, unless the `average` keyword is set to `yes`. The value of the displacement will be 0.0 for atoms not in the specified compute group.

If the `com` option is set to `yes` then the effect of any drift in the center-of-mass of the group of atoms is subtracted out before the displacement of each atom is calculated.

If the `average` option is set to `yes` then the reference position of an atom is based on the average position of that atom, corrected for center-of-mass motion if requested. The average position is a running average over all previous calls to the compute, including the current call. So on the first call it is current position, on the second call it is the arithmetic average of the current position and the position on the first call, and so on. Note that when using this option, the precise value of the mean square displacement will depend on the number of times the compute is called. So, for example, changing the frequency of thermo output may change the computed displacement. Also, the precise values will be changed if a single simulation is broken up into two parts, using either multiple run commands or a restart file. It only makes sense to use this option if the atoms are not diffusing, so that their average positions relative to the center of mass of the system are stationary. The most common case is crystalline solids undergoing thermal motion.

**Note:** Initial coordinates are stored in “unwrapped” form, by using the image flags associated with each atom. See the `dump custom` command for a discussion of “unwrapped” coordinates. See the Atoms section of the `read_data` command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the `set image` command.

**Note:** If you want the quantities calculated by this compute to be continuous when running from a restart file, then you should use the same ID for this compute, as in the original run. This is so that the fix this compute creates to store per-atom quantities will also have the same ID, and thus be initialized correctly with atom reference positions from the restart file. When `average` is set to `yes`, then the atom reference positions are restored correctly, but not the number of samples used obtain them. As a result, the reference positions from the restart file are combined with subsequent positions as if they were from a single sample, instead of many, which will change the values of msd somewhat.
18.64.4 Output info

This compute calculates a global vector of length 4, which can be accessed by indices 1-4 by any command that uses global vector values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The vector values are “intensive”. The vector values will be in distance^2 units.

18.64.5 Restrictions

Compute msd cannot be used with a dynamic group.

```

18.65.3 Description

Define a computation that calculates the mean-squared displacement (MSD) for multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a compute chunk/atom command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the compute chunk/atom and Howto chunk doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

Four quantities are calculated by this compute for each chunk. The first 3 quantities are the squared dx,dy,dz displacements of the center-of-mass. The fourth component is the total squared displacement, i.e. (dx*dx + dy*dy + dz*dz) of the center-of-mass. These calculations include all effects due to atoms passing through periodic boundaries.
Note that only atoms in the specified group contribute to the calculation. The `compute chunk/atom` command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

The slope of the mean-squared displacement (MSD) versus time is proportional to the diffusion coefficient of the diffusing chunks.

The displacement of the center-of-mass of the chunk is from its original center-of-mass position, calculated on the timestep this compute command was first invoked.

**Note:** The number of chunks $N_{chunk}$ calculated by the `compute chunk/atom` command must remain constant each time this compute is invoked, so that the displacement for each chunk from its original position can be computed consistently. If $N_{chunk}$ does not remain constant, an error will be generated. If needed, you can enforce a constant $N_{chunk}$ by using the `nchunk once` or `ids once` options when specifying the `compute chunk/atom` command.

**Note:** This compute stores the original position (of the center-of-mass) of each chunk. When a displacement is calculated on a later timestep, it is assumed that the same atoms are assigned to the same chunk ID. However LAMMPS has no simple way to insure this is the case, though you can use the `ids once` option when specifying the `compute chunk/atom` command. Note that if this is not the case, the MSD calculation does not have a sensible meaning.

**Note:** The initial coordinates of the atoms in each chunk are stored in “unwrapped” form, by using the image flags associated with each atom. See the `dump custom` command for a discussion of “unwrapped” coordinates. See the Atoms section of the `read_data` command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the `set image` command.

**Note:** If you want the quantities calculated by this compute to be continuous when running from a restart file, then you should use the same ID for this compute, as in the original run. This is so that the fix this compute creates to store per-chunk quantities will also have the same ID, and thus be initialized correctly with chunk reference positions from the restart file.

The simplest way to output the results of the compute msd/chunk calculation to a file is to use the `fix ave/time` command, for example:

```
compute ccl all chunk/atom molecule
compute myChunk all msd/chunk ccl
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
```

### 18.65.4 Output info

This compute calculates a global array where the number of rows = the number of chunks $N_{chunk}$ as calculated by the specified `compute chunk/atom` command. The number of columns = 4 for dx,dy,dz and the total displacement. These values can be accessed by any command that uses global array values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in distance^2 units.
18.65.5 Restrictions

none

18.65.6 Related commands

18.66 compute msd/nongauss command

18.66.1 Syntax

```
compute ID group-ID msd/nongauss keyword values ...
```

- ID, group-ID are documented in `compute` command
- msd/nongauss = style name of this compute command
- zero or more keyword/value pairs may be appended
- keyword = com
  - com value = yes or no

18.66.2 Examples

```
compute 1 all msd/nongauss
compute 1 upper msd/nongauss com yes
```

18.66.3 Description

Define a computation that calculates the mean-squared displacement (MSD) and non-Gaussian parameter (NGP) of the group of atoms, including all effects due to atoms passing through periodic boundaries.

A vector of three quantities is calculated by this compute. The first element of the vector is the total squared dx,dy,dz displacements 
\[ \text{drsquared} = (dx*dx + dy*dy + dz*dz) \]
of atoms, and the second is the fourth power of these displacements 
\[ \text{drfourth} = (dx*dx + dy*dy + dz*dz)*(dx*dx + dy*dy + dz*dz) \]
summed and averaged over atoms in the group. The third component is the non-Gaussian diffusion parameter 
\[ \text{NGP} = \frac{3*\text{drfourth}}{5*\text{drsquared}^2} - 1 \]

The NGP is a commonly used quantity in studies of dynamical heterogeneity. Its minimum theoretical value (-0.4) occurs when all atoms have the same displacement magnitude. NGP=0 for Brownian diffusion, while NGP > 0 when some mobile atoms move faster than others.

If the com option is set to yes then the effect of any drift in the center-of-mass of the group of atoms is subtracted out before the displacement of each atom is calculated.
See the *compute msd* page for further important NOTEs, which also apply to this compute.

18.66.4 Output info

This compute calculates a global vector of length 3, which can be accessed by indices 1-3 by any command that uses global vector values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

The vector values are “intensive”. The first vector value will be in distance^2 units, the second is in distance^4 units, and the third is dimensionless.

18.66.5 Restrictions

Compute *msd/nongauss* cannot be used with a dynamic group.

This compute is part of the EXTRA-COMPUTE package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

18.66.6 Related commands

*compute msd*

18.66.7 Default

The option default is com = no.

18.67 compute nbond/atom command

18.67.1 Syntax

```plaintext
compute ID group-ID nbond/atom
```

- ID, group-ID are documented in *compute* command
- nbond/atom = style name of this compute command

18.67.2 Examples

```plaintext
compute 1 all nbond/atom
```
18.67.3 Description

Define a computation that computes the number of bonds each atom is part of. Bonds which are broken are not counted in the tally. See the How to broken bonds page for more information. The number of bonds will be zero for atoms not in the specified compute group. This compute does not depend on Newton bond settings.

18.67.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the How to output doc page for an overview of LAMMPS output options.

18.67.5 Restrictions

This fix can only be used if LAMMPS was built with the BPM package. See the Build package doc page for more info.

18.68 compute omega/chunk command

18.68.1 Syntax

```
compute ID group-ID omega/chunk chunkID
```

- ID, group-ID are documented in compute command
- omega/chunk = style name of this compute command
- chunkID = ID of compute chunk/atom command

18.68.2 Examples

```
compute 1 fluid omega/chunk molchunk
```

18.68.3 Description

Define a computation that calculates the angular velocity (omega) of multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a compute chunk/atom command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the compute chunk/atom and How to chunk doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.
This compute calculates the 3 components of the angular velocity vector for each chunk, via the formula $L = Iw$ where $L$ is the angular momentum vector of the chunk, $I$ is its moment of inertia tensor, and $w$ is the angular velocity of the chunk. The calculation includes all effects due to atoms passing through periodic boundaries.

Note that only atoms in the specified group contribute to the calculation. The `compute chunk/atom` command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

**Note:** The coordinates of an atom contribute to the chunk’s angular velocity in “unwrapped” form, by using the image flags associated with each atom. See the `dump custom` command for a discussion of “unwrapped” coordinates. See the Atoms section of the `read_data` command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the `set image` command.

The simplest way to output the results of the compute omega/chunk calculation to a file is to use the `fix ave/time` command, for example:

```
compute ccl all chunk/atom molecule
compute myChunk all omega/chunk ccl
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
```

### 18.68.4 Output info

This compute calculates a global array where the number of rows = the number of chunks $N_{chunk}$ as calculated by the specified `compute chunk/atom` command. The number of columns = 3 for the 3 xyz components of the angular velocity for each chunk. These values can be accessed by any command that uses global array values from a compute as input. See the `How to output` page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in velocity/distance units.

18.69 compute orientorder/atom command

Accelerator Variants: orientorder/atom/kk

18.69.1 Syntax

```
compute ID group-ID orientorder/atom keyword values ...
```

- ID, group-ID are documented in `compute` command
- orientorder/atom = style name of this compute command
- one or more keyword/value pairs may be appended

- `keyword = cutoff or nnn or degrees or components or chunksize`
- `cutoff` value = distance cutoff
- `nnn` value = number of nearest neighbors
- `degrees` values = nlvalues, l1, l2,...
- `wl` value = yes or no
- `wl/hat` value = yes or no
- `components` value = ldegree
- `chunksize` value = number of atoms in each pass

18.69.2 Examples

```
compute 1 all orientorder/atom
compute 1 all orientorder/atom degrees 5 4 6 8 10 12 nnn NULL cutoff 1.5
compute 1 all orientorder/atom wl/hat yes
compute 1 all orientorder/atom components 6
```

18.69.3 Description

Define a computation that calculates a set of bond-orientational order parameters $Q_l$ for each atom in a group. These order parameters were introduced by Steinhardt et al. as a way to characterize the local orientational order in atomic structures. For each atom, $Q_l$ is a real number defined as follows:

$$
\bar{Y}_{lm} = \frac{1}{nnn} \sum_{j=1}^{nnn} Y_{lm}(\theta(r_{ij}), \phi(r_{ij}))
$$

$$
Q_l = \sqrt{\frac{4\pi}{2l+1} \sum_{m=-l}^{m=l} \bar{Y}_{lm} \bar{Y}_{lm}^*}
$$

The first equation defines the local order parameters as averages of the spherical harmonics $Y_{lm}$ for each neighbor. These are complex number components of the 3D analog of the 2D order parameter $q_n$, which is implemented as LAMMPS compute `hexorder/atom`. The summation is over the $nnn$ nearest neighbors of the central atom. The angles $\theta$ and $\phi$ are the standard spherical polar angles defining the direction of the bond vector $r_{ij}$. The phase and sign of $Y_{lm}$ follow the standard conventions, so that $\text{sign}(Y_{l0}(0, 0)) = (-1)^l$. The second equation defines $Q_l$, which is a rotationally invariant non-negative amplitude obtained by summing over all the components of degree $l$.

The optional keyword `cutoff` defines the distance cutoff used when searching for neighbors. The default value, also the maximum allowable value, is the cutoff specified by the pair style.
The optional keyword *n*nn defines the number of nearest neighbors used to calculate *Q*ₙ. The default value is 12. If the value is NULL, then all neighbors up to the specified distance cutoff are used.

The optional keyword *degrees* defines the list of order parameters to be computed. The first argument *nlvalues* is the number of order parameters. This is followed by that number of non-negative integers giving the degree of each order parameter. Because *Q*₂ and all odd-degree order parameters are zero for atoms in cubic crystals (see Steinhardt), the default order parameters are *Q*₄, *Q*₆, *Q*₈, *Q*₁₀, and *Q*₁₂. For the FCC crystal with *n*nn =12, *Q*₄ = √(7/192) = 0.19094....

The numerical values of all order parameters up to *Q*₁₂ for a range of commonly encountered high-symmetry structures are given in Table I of Mickel et al., and these can be reproduced with this compute.

The optional keyword *wl* will output the third-order invariants *W*ₙ (see Eq. 1.4 in Steinhardt) for the same degrees as for the *Q*ₙ parameters. For the FCC crystal with *n*nn =12, *W*₄ = -sqrt(14/143);(49/4096)/Pi^1.5 = -0.0006722136...

The optional keyword *wl/what* will output the normalized third-order invariants *W*ₙ (see Eq. 2.2 in Steinhardt) for the same degrees as for the *Q*ₙ parameters. For the FCC crystal with *n*nn =12, *W*₄ = -7/3 *sqrt(2/49) = -0.159317...

The numerical values of *W*ₙ for a range of commonly encountered high-symmetry structures are given in Table I of Steinhardt, and these can be reproduced with this keyword.

The optional keyword *components* will output the components of the normalized complex vector *Y*ₙₙₙₙ = *Y*ₙₙₙₙ/|*Y*ₙₙₙₙ| of degree *ldegree*, which must be included in the list of order parameters to be computed. This option can be used in conjunction with compute coord_atom to calculate the ten Wolde’s criterion to identify crystal-like particles, as discussed in ten Wolde.

The optional keyword *chunksize* is only applicable when using the the KOKKOS package and is ignored otherwise. This keyword controls the number of atoms in each pass used to compute the bond-orientational order parameters and is used to avoid running out of memory. For example if there are 32768 atoms in the simulation and the *chunksize* is set to 16384, the parameter calculation will be broken up into two passes.

The value of *Q*ₙ is set to zero for atoms not in the specified compute group, as well as for atoms that have less than *n*nn neighbors within the distance cutoff, unless *n*nn is NULL.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently.

**Note:** If you have a bonded system, then the settings of *special_bonds* command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the *special_bonds* command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses the neighbor list, it also means those pairs will not be included in the order parameter. This difficulty can be circumvented by writing a dump file, and using the rerun command to compute the order parameter for snapshots in the dump file. The rerun script can use a *special_bonds* command that includes all pairs in the neighbor list.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
18.69.4 Output info

This compute calculates a per-atom array with \( nl \) values columns, giving the \( Q_l \) values for each atom, which are real numbers on the range \( 0 \leq Q_l \leq 1 \).

If the keyword \( wl \) is set to yes, then the \( W_l \) values for each atom will be added to the output array, which are real numbers.

If the keyword \( wl/hat \) is set to yes, then the \( \hat{W}_l \) values for each atom will be added to the output array, which are real numbers.

If the keyword \( components \) is set, then the real and imaginary parts of each component of normalized \( \hat{Y}_{lm} \) will be added to the output array in the following order: \( \text{Re}(\hat{Y}_{-m}), \text{Im}(\hat{Y}_{-m}), \text{Re}(\hat{Y}_{m+1}), \text{Im}(\hat{Y}_{m+1}), \ldots, \text{Re}(\hat{Y}_m), \text{Im}(\hat{Y}_m) \).

In summary, the per-atom array will contain \( nl \) values columns, followed by an additional \( nl \) values columns if \( wl \) is set to yes, followed by an additional \( nl \) values columns if \( wl/hat \) is set to yes, followed by an additional \( 2*(2* \text{ldegree}+1) \) columns if the \( components \) keyword is set.

These values can be accessed by any command that uses per-atom values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

18.70 compute pair command

18.70.1 Syntax

\[ \text{compute ID group-ID pair pstyle [nstyle] [evalue]} \]

- \( \text{ID, group-ID are documented in compute command} \)
- \( \text{pair = style name of this compute command} \)
- \( \text{pstyle = style name of a pair style that calculates additional values} \)
- \( \text{nsub = n-instance of a sub-style, if a pair style is used multiple times in a hybrid style} \)
• `evalue = epair or evdwl or ecoul` or blank (optional)

### 18.70.2 Examples

```plaintext
compute 1 all pair gauss
compute 1 all pair lj/cut/coul/cut ecul
compute 1 all pair tersoff 2 epair
compute 1 all pair reaxff
```

### 18.70.3 Description

Define a computation that extracts additional values calculated by a pair style, and makes them accessible for output or further processing by other commands.

**Note:** The group specified for this command is ignored.

The specified `pstyle` must be a pair style used in your simulation either by itself or as a sub-style in a `pair_style hybrid` or `hybrid/overlay` command. If the sub-style is used more than once, an additional number `nsub` has to be specified in order to choose which instance of the sub-style will be used by the compute. Not specifying the number in this case will cause the compute to fail.

The `evalue` setting is optional. All pair styles tally a potential energy `epair` which may be broken into two parts: `evdwl` and `ecoul` such that `epair = evdwl + ecoul`. If the pair style calculates Coulombic interactions, their energy will be tallied in `ecoul`. Everything else (whether it is a Lennard-Jones style van der Waals interaction or not) is tallied in `evdwl`. If `evalue` is blank or specified as `epair`, then `epair` is stored as a global scalar by this compute. This is useful when using `pair_style hybrid` if you want to know the portion of the total energy contributed by one sub-style. If `evalue` is specified as `evdwl` or `ecoul`, then just that portion of the energy is stored as a global scalar.

**Note:** The energy returned by the `evdwl` keyword does not include tail corrections, even if they are enabled via the `pair_modify` command.

Some pair styles tally additional quantities, e.g. a breakdown of potential energy into 14 components is tallied by the `pair_style reaxff` command. These values (1 or more) are stored as a global vector by this compute. See the page for individual pair styles for info on these values.

### 18.70.4 Output info

This compute calculates a global scalar which is `epair` or `evdwl` or `ecoul`. If the pair style supports it, it also calculates a global vector of length >= 1, as determined by the pair style. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The scalar and vector values calculated by this compute are “extensive”.

The scalar value will be in energy units. The vector values will typically also be in energy units, but see the page for the pair style for details.

compute 1 all pair/local dist eng force
compute 1 all pair/local dist eng fx fy fz
compute 1 all pair/local dist fx fy fz p1 p2 p3
\end{verbatim}
18.71.3 Description

Define a computation that calculates properties of individual pairwise interactions. The number of datums generated, aggregated across all processors, equals the number of pairwise interactions in the system.

The local data stored by this command is generated by looping over the pairwise neighbor list. Info about an individual pairwise interaction will only be included if both atoms in the pair are in the specified compute group, and if the current pairwise distance is less than the force cutoff distance for that interaction, as defined by the `pair_style` and `pair_coeff` commands.

The value `dist` is the distance between the pair of atoms. The values `dx`, `dy`, and `dz` are the xyz components of the `distance` between the pair of atoms. This value is always the distance from the atom of lower to the one with the higher id.

The value `eng` is the interaction energy for the pair of atoms.

The value `force` is the force acting between the pair of atoms, which is positive for a repulsive force and negative for an attractive force. The values `fx`, `fy`, and `fz` are the xyz components of `force` on atom I.

A pair style may define additional pairwise quantities which can be accessed as `p1` to `pN`, where N is defined by the pair style. Most pair styles do not define any additional quantities, so N = 0. An example of ones that do are the granular pair styles which calculate the tangential force between two particles and return its components and magnitude acting on atom I for N = 1,2,3,4. See individual pair styles for details.

When using `pN` with pair style `hybrid`, the output will be the Nth quantity from the sub-style that computes the pairwise interaction (based on atom types). If that sub-style does not define a `pN`, the output will be 0.0. The maximum allowed N is the maximum number of quantities provided by any sub-style.

When using `pN` with pair style `hybrid/overlay` the quantities from all sub-styles that provide them are concatenated together into one long list. For example, if there are 3 sub-styles and 2 of them have additional output (with 3 and 4 quantities, respectively), then 7 values (p1 up to p7) are defined. The values p1 to p3 refer to quantities defined by the first of the two sub-styles. Values p4 to p7 refer to quantities from the second of the two sub-styles. If the referenced `pN` is not computed for the specific pairwise interaction (based on atom types), then the output will be 0.0.

The value `dist`, `dx`, `dy` and `dz` will be in distance `units`. The value `eng` will be in energy `units`. The values `force`, `fx`, `fy`, and `fz` will be in force `units`. The values `pN` will be in whatever units the pair style defines.

The optional `cutoff` keyword determines how the force cutoff distance for an interaction is determined. For the default setting of `type`, the pairwise cutoff defined by the `pair_style` command for the types of the two atoms is used. For the `radius` setting, the sum of the radii of the two particles is used as a cutoff. For example, this is appropriate for granular particles which only interact when they are overlapping, as computed by granular pair styles. Note that if a granular model defines atom types such that all particles of a specific type are monodisperse (same diameter), then the two settings are effectively identical.

Note that as atoms migrate from processor to processor, there will be no consistent ordering of the entries within the local vector or array from one timestep to the next. The only consistency that is guaranteed is that the ordering on a particular timestep will be the same for local vectors or arrays generated by other compute commands. For example, pair output from the `compute property/local` command can be combined with data from this command and output by the `dump local` command in a consistent way.

Here is an example of how to do this:

```
compute 1 all property/local patom1 patom2
compute 2 all pair/local dist eng force
```

Note: For pairs, if two atoms I,J are involved in 1-2, 1-3, 1-4 interactions within the molecular topology, their pairwise interaction may be turned off, and thus they may not appear in the neighbor list, and will not be part of the local data created by this command. More specifically, this will be true of I,J pairs with a weighting factor of 0.0; pairs with
a non-zero weighting factor are included. The weighting factors for 1-2, 1-3, and 1-4 pairwise interactions are set
by the special_bonds command. An exception is if long-range Coulombics are being computed via the kspace_style
command, then atom pairs with weighting factors of zero are still included in the neighbor list, so that a portion of the
long-range interaction contribution can be computed in the pair style. Hence in that case, those atom pairs will be part
of the local data created by this command.

18.71.4 Output info

This compute calculates a local vector or local array depending on the number of keywords. The length of the vector
or number of rows in the array is the number of pairs. If a single keyword is specified, a local vector is produced. If
two or more keywords are specified, a local array is produced where the number of columns = the number of keywords.
The vector or array can be accessed by any command that uses local values from a compute as input. See the Howto
output page for an overview of LAMMPS output options.

The output for dist will be in distance units. The output for eng will be in energy units. The output for force, fx, fy, and
fz will be in force units. The output for pN will be in whatever units the pair style defines.

```

18.72.3 Description

Define a computation that calculates the potential energy of the entire system of atoms. The specified group must be “all”. See the `compute pe/atom` command if you want per-atom energies. These per-atom values could be summed for a group of atoms via the `compute reduce` command.

The energy is calculated by the various pair, bond, etc potentials defined for the simulation. If no extra keywords are listed, then the potential energy is the sum of pair, bond, angle, dihedral, improper, kspace (long-range), and fix energy. I.e. it is as if all the keywords were listed. If any extra keywords are listed, then only those components are summed to compute the potential energy.

The Kspace contribution requires 1 extra FFT each timestep the energy is calculated, if using the PPPM solver via the `kspace_style pppm` command. Thus it can increase the cost of the PPPM calculation if it is needed on a large fraction of the simulation timesteps.

Various fixes can contribute to the total potential energy of the system if the fix contribution is included. See the doc pages for individual fixes for details of which ones compute a potential energy.

**Note:** The `fix_modify energy yes` command must also be specified if a fix is to contribute potential energy to this command.

A compute of this style with the ID of “thermo_pe” is created when LAMMPS starts up, as if this command were in the input script:

```
compute thermo_pe all pe
```

See the “thermo_style” command for more details.

18.72.4 Output info

This compute calculates a global scalar (the potential energy). This value can be used by any command that uses a global scalar value from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “extensive”. The scalar value will be in energy units.
18.72.5 Restrictions

none

18.73 compute pe/atom command

18.73.1 Syntax

compute ID group-ID pe/atom keyword ...

- ID, group-ID are documented in compute command
- pe/atom = style name of this compute command
- zero or more keywords may be appended
- keyword = pair or bond or angle or dihedral or improper or kspace or fix

18.73.2 Examples

compute 1 all pe/atom
compute 1 all pe/atom pair
compute 1 all pe/atom pair bond

18.73.3 Description

Define a computation that computes the per-atom potential energy for each atom in a group. See the compute pe command if you want the potential energy of the entire system.

The per-atom energy is calculated by the various pair, bond, etc potentials defined for the simulation. If no extra keywords are listed, then the potential energy is the sum of pair, bond, angle, dihedral,improper, kspace (long-range), and fix energy. I.e. it is as if all the keywords were listed. If any extra keywords are listed, then only those components are summed to compute the potential energy.

Note that the energy of each atom is due to its interaction with all other atoms in the simulation, not just with other atoms in the group.

For an energy contribution produced by a small set of atoms (e.g. 4 atoms in a dihedral or 3 atoms in a Tersoff 3-body interaction), that energy is assigned in equal portions to each atom in the set. E.g. 1/4 of the dihedral energy to each of the 4 atoms.

The dihedral_style charm m style calculates pairwise interactions between 1-4 atoms. The energy contribution of these terms is included in the pair energy, not the dihedral energy.
The KSpace contribution is calculated using the method in (Heyes) for the Ewald method and a related method for PPPM, as specified by the kspace_style ppm command. For PPPM, the calculation requires 1 extra FFT each timestep that per-atom energy is calculated. This document describes how the long-range per-atom energy calculation is performed.

Various fixes can contribute to the per-atom potential energy of the system if the fix contribution is included. See the doc pages for individual fixes for details of which ones compute a per-atom potential energy.

Note: The fix_modify energy yes command must also be specified if a fix is to contribute per-atom potential energy to this command.

As an example of per-atom potential energy compared to total potential energy, these lines in an input script should yield the same result in the last 2 columns of thermo output:

```plaintext
compute     peratom all pe/atom
compute     pe all reduce sum c_peratom
thermo_style custom step temp etotal press pe c_pe
```

Note: The per-atom energy does not include any Lennard-Jones tail corrections to the energy added by the pair_modify tail yes command, since those are contributions to the global system energy.

### 18.73.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The per-atom vector values will be in energy units.

- ID, group-ID are documented in compute command
- plasticity/atom = style name of this compute command

18.74.2 Examples

```
compute 1 all plasticity/atom
```

18.74.3 Description

Define a computation that calculates the per-atom plasticity for each atom in a group. This is a quantity relevant for Peridynamics models. See this document for an overview of LAMMPS commands for Peridynamics modeling.

The plasticity for a Peridynamic particle is the so-called consistency parameter (lambda). For elastic deformation lambda = 0, otherwise lambda > 0 for plastic deformation. For details, see (Mitchell) and the PDF doc included in the LAMMPS distribution in doc/PDF/PDLammps_EPS.pdf.

This command can be invoked for one of the Peridynamic pair styles: peri/eps.

The plasticity value will be 0.0 for atoms not in the specified compute group.

18.74.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The per-atom vector values are unitless numbers (lambda) >= 0.0.

18.74.5 Restrictions

This compute is part of the PERI package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

\]

- ID, group-ID are documented in compute command
- pressure = style name of this compute command
- temp-ID = ID of compute that calculates temperature, can be NULL if not needed
- zero or more keywords may be appended
- keyword = ke or pair or bond or angle or dihedral or improper or kspace or fix or virial or pair/hybrid

18.75.2 Examples

\[
\begin{align*}
\text{compute} & \quad 1 \text{ all} \quad \text{pressure thermo_temp} \\
\text{compute} & \quad 1 \text{ all} \quad \text{pressure NULL pair bond} \\
\text{compute} & \quad 1 \text{ all} \quad \text{pressure NULL pair/hybrid lj/cut}
\end{align*}
\]

18.75.3 Description

Define a computation that calculates the pressure of the entire system of atoms. The specified group must be “all”. See the compute stress/atom command if you want per-atom pressure (stress). These per-atom values could be summed for a group of atoms via the compute reduce command.

The pressure is computed by the formula

\[
P = \frac{N k_B T}{V} + \frac{\sum_{i} N' r_i \cdot f_i}{dV}
\]

where \( N \) is the number of atoms in the system (see discussion of DOF below), \( k_B \) is the Boltzmann constant, \( T \) is the temperature, \( d \) is the dimensionality of the system (2 or 3 for 2d/3d), and \( V \) is the system volume (or area in 2d). The second term is the virial, equal to -dU/dV, computed for all pairwise as well as 2-body, 3-body, 4-body, many-body, and long-range interactions, where \( r_i \) and \( f_i \) are the position and force vector of atom \( i \), and the black dot indicates a dot product. This is computed in parallel for each sub-domain and then summed over all parallel processes. Thus \( N' \) necessarily includes atoms from neighboring sub-domains (so-called ghost atoms) and the position and force vectors of ghost atoms are thus included in the summation. Only when running in serial and without periodic boundary conditions is \( N' = N = \) the number of atoms in the system. Fixes that impose constraints (e.g. the fix shake command) may also contribute to the virial term.

A symmetric pressure tensor, stored as a 6-element vector, is also calculated by this compute. The 6 components of the vector are ordered xx, yy, zz, xy, xz, yz. The equation for the IJ components (where I and J = x,y,z) is similar to
the above formula, except that the first term uses components of the kinetic energy tensor and the second term uses components of the virial tensor:

\[ P_{IJ} = \sum_{k} N_{k} m_{k} v_{kI} v_{kJ} + \sum_{k} N'_{k} f_{kI} f_{kJ} \]

If no extra keywords are listed, the entire equations above are calculated. This includes a kinetic energy (temperature) term and the virial as the sum of pair, bond, angle, dihedral, improper, kspace (long-range), and fix contributions to the force on each atom. If any extra keywords are listed, then only those components are summed to compute temperature or ke and/or the virial. The \textit{virial} keyword means include all terms except the kinetic energy \textit{ke}.

The \textit{pair/hybrid} keyword means to only include contribution from a sub-style in a \textit{hybrid} or \textit{hybrid/overlay} pair style.

Details of how LAMMPS computes the virial efficiently for the entire system, including for many-body potentials and accounting for the effects of periodic boundary conditions are discussed in (Thompson).

The temperature and kinetic energy tensor is not calculated by this compute, but rather by the temperature compute specified with the command. If the kinetic energy is not included in the pressure, than the temperature compute is not used and can be specified as NULL. Normally the temperature compute used by compute pressure should calculate the temperature of all atoms for consistency with the virial term, but any compute style that calculates temperature can be used, e.g. one that excludes frozen atoms or other degrees of freedom.

Note that if desired the specified temperature compute can be one that subtracts off a bias to calculate a temperature using only the thermal velocity of the atoms, e.g. by subtracting a background streaming velocity. See the doc pages for individual \textit{compute commands} to determine which ones include a bias.

Also note that the N in the first formula above is really degrees-of-freedom divided by \( d = \) dimensionality, where the DOF value is calculated by the temperature compute. See the various \textit{compute temperature} styles for details.

A compute of this style with the ID of “thermo_press” is created when LAMMPS starts up, as if this command were in the input script:

```
compute thermo_press all pressure thermo_temp
```

where “thermo_temp” is the ID of a similarly defined compute of style “temp”. See the “thermo_style” command for more details.

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Accelerator packages} page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \textit{-suffix command-line switch} when you invoke LAMMPS, or you can use the \textit{suffix} command in your input script.

See the \textit{Accelerator packages} page for more instructions on how to use the accelerated styles effectively.
18.75.4 Output info

This compute calculates a global scalar (the pressure) and a global vector of length 6 (pressure tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The ordering of values in the symmetric pressure tensor is as follows: pxx, pyy, pzz, pxy, pxz, pyz.

The scalar and vector values calculated by this compute are “intensive”. The scalar and vector values will be in pressure units.

```

18.77.3 Description

Define a computation that simply stores atom attributes for each atom in the group. This is useful so that the values can be used by other output commands that take computes as inputs. See for example, the compute reduce, fix ave/atom, fix ave/histo, fix ave/chunk, and atom-style variable commands.

The list of possible attributes is essentially the same as that used by the dump custom command, which describes their meaning, with some additional quantities that are only defined for certain atom styles. The goal of this augmented list gives an input script access to any per-atom quantity stored by LAMMPS.

The values are stored in a per-atom vector or array as discussed below. Zeroes are stored for atoms not in the specified group or for quantities that are not defined for a particular particle in the group (e.g. shapex if the particle is not an ellipsoid).

Attributes \( i\_name \), \( d\_name \), \( i2\_name \), \( d2\_name \) refer to custom per-atom integer and floating-point vectors or arrays that have been added via the fix property/atom command. When that command is used specific names are given to each attribute which are the “name” portion of these attributes. For arrays \( i2\_name \) and \( d2\_name \), the column of the array must also be included following the name in brackets: e.g. \( d2\_xyz[2] \), \( i2\_mySpin[3] \).

The additional quantities only accessible via this command, and not directly via the dump custom command, are as follows.

\( N\_bonds \) is available for all molecular atom styles and refers to the number of explicit bonds assigned to an atom. Note that if the newton bond command is set to on, which is the default, then every bond in the system is assigned to only one of the two atoms in the bond. Thus a bond between atoms I,J may be tallied for either atom I or atom J. If newton bond off is set, it will be tallied with both atom I and atom J.

\( Shapex \), \( shapey \), and \( shapez \) are defined for ellipsoidal particles and define the 3d shape of each particle.

\( Quatw \), \( quati \), \( quatj \), and \( quatk \) are defined for ellipsoidal particles and body particles and store the 4-vector quaternion representing the orientation of each particle. See the set command for an explanation of the quaternion vector.

\( End1x \), \( end1y \), \( end1z \), \( end2x \), \( end2y \), \( end2z \), are defined for line segment particles and define the end points of each line segment.

\( Corner1x \), \( corner1y \), \( corner1z \), \( corner2x \), \( corner2y \), \( corner2z \), \( corner3x \), \( corner3y \), \( corner3z \), are defined for triangular particles and define the corner points of each triangle.

In addition, the various per-atom quantities listed above for specific packages are only accessible by this command.
18.77.4 Output info

This compute calculates a per-atom vector or per-atom array depending on the number of input values. If a single input is specified, a per-atom vector is produced. If two or more inputs are specified, a per-atom array is produced where the number of columns = the number of inputs. The vector or array can be accessed by any command that uses per-atom values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The vector or array values will be in whatever units the corresponding attribute is in, e.g. velocity units for vx, charge units for q, etc.

For the spin quantities, sp is in the units of the Bohr magneton, spx, spy, and spz are unitless quantities, and fmx, fmy and fmx are given in rad/THz.

18.78 compute property/chunk command

18.78.1 Syntax

| compute ID group-ID property/chunk chunkID input1 input2 ...

- ID, group-ID are documented in compute command
- property/chunk = style name of this compute command
- input = one or more attributes
  - attributes = count, id, coord1, coord2, coord3
  - count = # of atoms in chunk
  - id = original chunk IDs before compression by compute chunk/atom
  - coord123 = coordinates for spatial bins calculated by compute chunk/atom
18.78.2 Examples

```
compute 1 all property/chunk count
compute 1 all property/chunk ID coord1
```

18.78.3 Description

Define a computation that stores the specified attributes of chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a `compute chunk/atom` command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the `compute chunk/atom` and `Howto chunk` doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates and stores the specified attributes of chunks as global data so they can be accessed by other output commands and used in conjunction with other commands that generate per-chunk data, such as `compute com/chunk` or `compute msd/chunk`.

Note that only atoms in the specified group contribute to the calculation of the `count` attribute. The `compute chunk/atom` command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

The `count` attribute is the number of atoms in the chunk.

The `id` attribute stores the original chunk ID for each chunk. It can only be used if the `compress` keyword was set to `yes` for the `compute chunk/atom` command referenced by chunkID. This means that the original chunk IDs (e.g. molecule IDs) will have been compressed to remove chunk IDs with no atoms assigned to them. Thus a compressed chunk ID of 3 may correspond to an original chunk ID (molecule ID in this case) of 415. The `id` attribute will then be 415 for the third chunk.

The `coordN` attributes can only be used if a `binning` style was used in the `compute chunk/atom` command referenced by chunkID. For `bin/1d`, `bin/2d`, and `bin/3d` styles the attribute is the center point of the bin in the corresponding dimension. Style `bin/1d` only defines a `coord1` attribute. Style `bin/2d` adds a `coord2` attribute. Style `bin/3d` adds a `coord3` attribute.

Note that if the value of the `units` keyword used in the `compute chunk/atom command is box` or `lattice`, the `coordN` attributes will be in distance `units`. If the value of the `units` keyword is `reduced`, the `coordN` attributes will be in unitless reduced units (0-1).

The simplest way to output the results of the compute property/chunk calculation to a file is to use the `fix ave/time` command, for example:

```
compute ccl all chunk/atom molecule
compute myChunk1 all property/chunk ccl count
compute myChunk2 all com/chunk ccl
fix 1 all ave/time 100 1 100 c_myChunk1 c_myChunk2[*] file tmp.out mode vector
```
18.78.4 Output info

This compute calculates a global vector or global array depending on the number of input values. The length of the vector or number of rows in the array is the number of chunks.

This compute calculates a global vector or global array where the number of rows = the number of chunks \( N_{\text{chunk}} \) as calculated by the specified compute chunk/atom command. If a single input is specified, a global vector is produced. If two or more inputs are specified, a global array is produced where the number of columns = the number of inputs. The vector or array can be accessed by any command that uses global values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The vector or array values are “intensive”. The values will be unitless or in the units discussed above.

• keyword = cutoff
cutoff arg = type or radius

18.79.2 Examples

```compute 1 all property/local btype batom1 batom2
compute 1 all property/local atype aatom2```

18.79.3 Description

Define a computation that stores the specified attributes as local data so it can be accessed by other output commands. If the input attributes refer to bond information, then the number of datums generated, aggregated across all processors, equals the number of bonds in the system. Ditto for pairs, angles, etc.

If multiple attributes are specified then they must all generate the same amount of information, so that the resulting local array has the same number of rows for each column. This means that only bond attributes can be specified together, or angle attributes, etc. Bond and angle attributes can not be mixed in the same compute property/local command.

If the inputs are pair attributes, the local data is generated by looping over the pairwise neighbor list. Info about an individual pairwise interaction will only be included if both atoms in the pair are in the specified compute group. For natom1 and natom2, all atom pairs in the neighbor list are considered (out to the neighbor cutoff = force cutoff + neighbor skin). For patom1 and patom2, the distance between the atoms must be less than the force cutoff distance for that pair to be included, as defined by the pair_style and pair_coeff commands.

The optional cutoff keyword determines how the force cutoff distance for an interaction is determined for the patom1 and patom2 attributes. For the default setting of type, the pairwise cutoff defined by the pair_style command for the types of the two atoms is used. For the radius setting, the sum of the radii of the two particles is used as a cutoff. For example, this is appropriate for granular particles which only interact when they are overlapping, as computed by granular pair styles. Note that if a granular model defines atom types such that all particles of a specific type are monodisperse (same diameter), then the two settings are effectively identical.

If the inputs are bond, angle, etc attributes, the local data is generated by looping over all the atoms owned on a processor and extracting bond, angle, etc info. For bonds, info about an individual bond will only be included if both atoms in the bond are in the specified compute group. Likewise for angles, dihedrals, etc.

For bonds and angles, a bonds/angles that have been broken by setting their bond/angle type to 0 will not be included. Bonds/angles that have been turned off (see the fix shake or delete_bonds commands) by setting their bond/angle type negative are written into the file. This is consistent with the compute bond/local and compute angle/local commands.

Note that as atoms migrate from processor to processor, there will be no consistent ordering of the entries within the local vector or array from one timestep to the next. The only consistency that is guaranteed is that the ordering on a particular timestep will be the same for local vectors or arrays generated by other compute commands. For example, output from the compute bond/local command can be combined with bond atom indices from this command and output by the dump local command in a consistent way.
The `natom1` and `natom2`, or `patom1` and `patom2` attributes refer to the atom IDs of the 2 atoms in each pairwise interaction computed by the `pair_style` command. The `ntype1` and `ntype2`, or `ptype1` and `ptype2` attributes refer to the atom types of the 2 atoms in each pairwise interaction.

**Note:** For pairs, if two atoms I,J are involved in 1-2, 1-3, 1-4 interactions within the molecular topology, their pairwise interaction may be turned off, and thus they may not appear in the neighbor list, and will not be part of the local data created by this command. More specifically, this may be true of I,J pairs with a weighting factor of 0.0; pairs with a non-zero weighting factor are included. The weighting factors for 1-2, 1-3, and 1-4 pairwise interactions are set by the `special_bonds` command.

The `batom1` and `batom2` attributes refer to the atom IDs of the 2 atoms in each bond. The `btype` attribute refers to the type of the bond, from 1 to Ntypes = # of bond types. The number of bond types is defined in the data file read by the `read_data` command.

The attributes that start with “a”, “d”, “i”, refer to similar values for angles, dihedrals, and impropers.

### 18.79.4 Output info

This compute calculates a local vector or local array depending on the number of input values. The length of the vector or number of rows in the array is the number of bonds, angles, etc. If a single input is specified, a local vector is produced. If two or more inputs are specified, a local array is produced where the number of columns = the number of inputs. The vector or array can be accessed by any command that uses local values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The vector or array values will be integers that correspond to the specified attribute.

### 18.79.5 Restrictions

none

### 18.79.6 Related commands

dump local, compute reduce

### 18.79.7 Default

The keyword default is `cutoff = type`.

### 18.80 compute ptm/atom command

#### 18.80.1 Syntax

```
compute ID group-ID ptm/atom structures threshold group2-ID
```

- ID, group-ID are documented in compute command
- `ptm/atom` = style name of this compute command
- `structures` = structure types to search for
• threshold = lattice distortion threshold (RMSD)
• group2-ID determines which group is used for neighbor selection (optional, default “all”)

18.80.2 Examples

```
compute 1 all ptm/atom default 0.1 all
compute 1 all ptm/atom fcc-hcp-dcub-dhex 0.15 all
compute 1 all ptm/atom all 0
```

18.80.3 Description

Define a computation that determines the local lattice structure around an atom using the PTM (Polyhedral Template Matching) method. The PTM method is described in (Larsen).

Currently, there are seven lattice structures PTM recognizes:

• fcc = 1
• hcp = 2
• bcc = 3
• ico (icosahedral) = 4
• sc (simple cubic) = 5
• dcub (diamond cubic) = 6
• dhex (diamond hexagonal) = 7
• graphene = 8

The value of the PTM structure will be 0 for unknown types and -1 for atoms not in the specified compute group. The choice of structures to search for can be specified using the “structures” argument, which is a hyphen-separated list of structure keywords. Two convenient pre-set options are provided:

• default: fcc-hcp-bcc-ico
• all: fcc-hcp-bcc-ico-sc-dcub-dhex-graphene

The ‘default’ setting detects the same structures as the Common Neighbor Analysis method. The ‘all’ setting searches for all structure types. A performance penalty is incurred for the diamond and graphene structures, so it is not recommended to use this option if it is known that the simulation does not contain these structures.

PTM identifies structures using two steps. First, a graph isomorphism test is used to identify potential structure matches. Next, the deviation is computed between the local structure (in the simulation) and a template of the ideal lattice structure. The deviation is calculated as:

\[ \text{RMSD}(\mathbf{u}, \mathbf{v}) = \min_{s, Q} \sqrt{\frac{1}{N} \sum_{i=1}^{N} ||s[u_i] - Qv_i||^2} \]

Here, \( \mathbf{u} \) and \( \mathbf{v} \) contain the coordinates of the local and ideal structures respectively, \( s \) is a scale factor, and \( Q \) is a rotation. The best match is identified by the lowest RMSD value, using the optimal scaling, rotation, and correspondence between the points.

The ‘threshold’ keyword sets an upper limit on the maximum permitted deviation before a local structure is identified as disordered. Typical values are in the range 0.1-0.15, but larger values may be desirable at higher temperatures. A value of 0 is equivalent to infinity and can be used if no threshold is desired.
The neighbor list needed to compute this quantity is constructed each time the calculation is performed (e.g. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently or to have multiple compute/dump commands, each with a ptm/atom style. By default the compute processes all neighbors unless the optional group2-ID argument is given, then only members of that group are considered as neighbors.

18.80.4 Output info

This compute calculates a per-atom array, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

Results are stored in the per-atom array in the following order:

- type
- rmsd
- interatomic distance
- qw
- qx
- qy
- qz

The type is a number from -1 to 8. The rmsd is a positive real number. The interatomic distance is computed from the scale factor in the RMSD equation. The (qw,qx,qy,qz) parameters represent the orientation of the local structure in quaternion form. The reference coordinates for each template (from which the orientation is determined) can be found in the ptm_constants.h file in the PTM source directory. For atoms that are not within the compute group-ID, all values are set to zero.

18.80.5 Restrictions

This fix is part of the PTM package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

(Larsen) Larsen, Schmidt, Schiotz, Modelling Simul Mater Sci Eng, 24, 055007 (2016).
18.81  compute rdf command

18.81.1  Syntax

```
compute ID group-ID rdf Nbin itype1 jtype1 itype2 jtype2 ... keyword/value ...
```

- ID, group-ID are documented in `compute` command
- `rdf` = style name of this compute command
- `Nbin` = number of RDF bins
- `itypeN` = central atom type for Nth RDF histogram (see asterisk form below)
- `jtypeN` = distribution atom type for Nth RDF histogram (see asterisk form below)
- zero or more keyword/value pairs may be appended
- `keyword = cutoff`
  - `cutoff` value = `Rcut`
    - `Rcut` = cutoff distance for RDF computation (distance units)

18.81.2  Examples

```
compute 1 all rdf 100
compute 1 all rdf 100 1 1
compute 1 all rdf 100 * 3 cutoff 5.0
compute 1 fluid rdf 500 1 1 1 2 2 1 2 2
compute 1 fluid rdf 500 1*3 2 5 *10 cutoff 3.5
```

18.81.3  Description

Define a computation that calculates the radial distribution function (RDF), also called \( g(r) \), and the coordination number for a group of particles. Both are calculated in histogram form by binning pairwise distances into \( Nbin \) bins from 0.0 to the maximum force cutoff defined by the `pair_style` command or the cutoff distance \( R_{cut} \) specified via the `cutoff` keyword. The bins are of uniform size in radial distance. Thus a single bin encompasses a thin shell of distances in 3d and a thin ring of distances in 2d.

**Note:** If you have a bonded system, then the settings of `special_bonds` command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the `special_bonds` command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses a neighbor list, it also means those pairs will not be included in the RDF. This does not apply when using long-range coulomb interactions (coul/long, coul/msm, coul/wolf or similar. One way to get around this would be to set `special_bond` scaling factors to very tiny numbers that are not exactly zero (e.g. 1.0e-50). Another workaround is to write a dump file, and use the `rerun` command to compute the RDF for snapshots in the dump file. The `rerun` script can use a `special_bonds` command that includes all pairs in the neighbor list.

By default the RDF is computed out to the maximum force cutoff defined by the `pair_style` command. If the `cutoff` keyword is used, then the RDF is computed accurately out to the \( R_{cut} > 0.0 \) distance specified.
Note: Normally, you should only use the cutoff keyword if no pair style is defined, e.g. the rerun command is being used to post-process a dump file of snapshots. Or if you really want the RDF for distances beyond the pair_style force cutoff and cannot easily post-process a dump file to calculate it. This is because using the cutoff keyword incurs extra computation and possibly communication, which may slow down your simulation. If you specify a Rcut <= force cutoff, you will force an additional neighbor list to be built at every timestep this command is invoked (or every reneighboring timestep, whichever is less frequent), which is inefficient. LAMMPS will warn you if this is the case. If you specify a Rcut > force cutoff, you must insure ghost atom information out to Rcut + skin is communicated, via the comm_modify cutoff command, else the RDF computation cannot be performed, and LAMMPS will give an error message. The skin value is what is specified with the neighbor command. In this case, you are forcing a large neighbor list to be built just for the RDF computation, and extra communication to be performed every timestep.

The itypeN and jtypeN arguments are optional. These arguments must come in pairs. If no pairs are listed, then a single histogram is computed for g(r) between all atom types. If one or more pairs are listed, then a separate histogram is generated for each itypeN,jtypeN pair.

The itypeN and jtypeN settings can be specified in one of two ways. An explicit numeric value can be used, as in the fourth example above. Or a wild-card card can be used to specify a range of atom types. This takes the form “*”, “*n” or “n*”, or “m*n”. If N = the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive).

If both itypeN and jtypeN are single values, as in the fourth example above, this means that a g(r) is computed where atoms of type itypeN are the central atom, and atoms of type jtypeN are the distribution atom. If either itypeN and jtypeN represent a range of values via the wild-card asterisk, as in the fifth example above, this means that a g(r) is computed where atoms of any of the range of types represented by itypeN are the central atom, and atoms of any of the range of types represented by jtypeN are the distribution atom.

Pairwise distances are generated by looping over a pairwise neighbor list, just as they would be in a pair_style computation. The distance between two atoms I and J is included in a specific histogram if the following criteria are met:

• atoms I,J are both in the specified compute group
• the distance between atoms I,J is less than the maximum force cutoff
• the type of the I atom matches itypeN (one or a range of types)
• the type of the J atom matches jtypeN (one or a range of types)

It is OK if a particular pairwise distance is included in more than one individual histogram, due to the way the itypeN and jtypeN arguments are specified.

The g(r) value for a bin is calculated from the histogram count by scaling it by the idealized number of how many counts there would be if atoms of type jtypeN were uniformly distributed. Thus it involves the count of itypeN atoms, the count of jtypeN atoms, the volume of the entire simulation box, and the volume of the bin’s thin shell in 3d (or the area of the bin’s thin ring in 2d).

A coordination number coord(r) is also calculated, which is the number of atoms of type jtypeN within the current bin or closer, averaged over atoms of type itypeN. This is calculated as the area- or volume-weighted sum of g(r) values over all bins up to and including the current bin, multiplied by the global average volume density of atoms of type jtypeN.

The simplest way to output the results of the compute rdf calculation to a file is to use the fix ave/time command, for example:

```
compute myRDF all rdf 50
fix 1 all ave/time 100 1 100 c_myRDF[*] file tmp.rdf mode vector
```
18.81.4 Output info

This compute calculates a global array with the number of rows = \( N_{bins} \), and the number of columns = \( 1 + 2 \times N_{pairs} \), where \( N_{pairs} \) is the number of I,J pairings specified. The first column has the bin coordinate (center of the bin). Each successive set of 2 columns has the \( g(r) \) and \( \text{coord}(r) \) values for a specific set of \( i_{type}N \) versus \( j_{type}N \) interactions, as described above. These values can be used by any command that uses a global values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The array values calculated by this compute are all “intensive”.

The first column of array values will be in distance *units*. The \( g(r) \) columns of array values are normalized numbers \( \geq 0.0 \). The coordinate number columns of array values are also numbers \( \geq 0.0 \).

18.81.5 Restrictions

The RDF is not computed for distances longer than the force cutoff, since processors (in parallel) don’t know about atom coordinates for atoms further away than that distance. If you want an RDF for larger distances, you can use the *rerun* command to post-process a dump file and set the cutoff for the potential to be longer in the rerun script. Note that in the rerun context, the force cutoff is arbitrary, since you are not running dynamics and thus are not changing your model. The definition of \( g(r) \) used by LAMMPS is only appropriate for characterizing atoms that are uniformly distributed throughout the simulation cell. In such cases, the coordination number is still correct and meaningful. As an example, if a large simulation cell contains only one atom of type \( i_{type}N \) and one of \( j_{type}N \), then \( g(r) \) will register an arbitrarily large spike at whatever distance they happen to be at, and zero everywhere else. \( \text{Coord}(r) \) will show a step change from zero to one at the location of the spike in \( g(r) \).

**Note:** compute rdf can handle dynamic groups and systems where atoms are added or removed, but this causes that certain normalization parameters need to be re-computed in every step and include collective communication operations. This will reduce performance and limit parallel efficiency and scaling. For systems, where only the type of atoms changes (e.g. when using *fix atom/swap*), you need to explicitly request the dynamic normalization updates via *compute_modify dynamic yes*.

18.81.6 Related commands

| f_ID = per-atom or local vector calculated by a fix with ID |
| f_ID[I] = Ith column of per-atom or local array calculated by a fix with ID, I can include wildcard (see below) |
| v_name = per-atom vector calculated by an atom-style variable with name |

• zero or more keyword/args pairs may be appended

• keyword = replace

  replace args = vec1 vec2
  vec1 = reduced value from this input vector will be replaced
  vec2 = replace it with vec1[N] where N is index of max/min value from vec2

18.83.2 Examples

```
compute 1 all reduce sum c_force
compute 1 all reduce/region subbox sum c_force
compute 2 all reduce min c_press[2] f_ave v_myKE
compute 2 all reduce min c_press[*] f_ave v_myKE
compute 3 fluid reduce max c_index[1] c_index[2] c_dist replace 1 3 replace 2 3
```

18.83.3 Description

Define a calculation that “reduces” one or more vector inputs into scalar values, one per listed input. The inputs can be per-atom or local quantities; they cannot be global quantities. Atom attributes are per-atom quantities, computes and fixes may generate any of the three kinds of quantities, and atom-style variables generate per-atom quantities. See the variable command and its special functions which can perform the same operations as the compute reduce command on global vectors.

The reduction operation is specified by the mode setting. The sum option adds the values in the vector into a global total. The min or max options find the minimum or maximum value across all vector values. The ave setting adds the vector values into a global total, then divides by the number of values in the vector. The sumsq option sums the square of the values in the vector into a global total. The avesq setting does the same as sumsq, then divides the sum of squares by the number of values. The last two options can be useful for calculating the variance of some quantity, e.g. variance = sumsq - ave^2. The sumabs option sums the absolute values in the vector into a global total. The aveabs setting does the same as sumabs, then divides the sum of absolute values by the number of values.

Each listed input is operated on independently. For per-atom inputs, the group specified with this command means only atoms within the group contribute to the result. For per-atom inputs, if the compute reduce/region command is used, the atoms must also currently be within the region. Note that an input that produces per-atom quantities may define
its own group which affects the quantities it returns. For example, if a compute is used as an input which generates a per-atom vector, it will generate values of 0.0 for atoms that are not in the group specified for that compute.

Each listed input can be an atom attribute (position, velocity, force component) or can be the result of a compute or fix or the evaluation of an atom-style variable.

Note that for values from a compute or fix, the bracketed index I can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “*” or “*n” or “n*” or “m*n”. If N = the size of the vector (for mode = scalar) or the number of columns in the array (for mode = vector), then an asterisk with no numeric values means all indices from 1 to N. A leading asterisk means all indices from 1 to n (inclusive). A trailing asterisk means all indices from m to n (inclusive).

Using a wildcard is the same as if the individual columns of the array had been listed one by one. E.g. these 2 compute reduce commands are equivalent, since the compute stress/atom command creates a per-atom array with 6 columns:

```
compute myPress all stress/atom NULL
compute 2 all reduce min c_myPress[*]
```

The atom attribute values (x,y,z,vx,vy,vz,fx,fy,fz) are self-explanatory. Note that other atom attributes can be used as inputs to this fix by using the compute property/atom command and then specifying an input value from that compute.

If a value begins with “c_”, a compute ID must follow which has been previously defined in the input script. Computes can generate per-atom or local quantities. See the individual compute page for details. If no bracketed integer is appended, the vector calculated by the compute is used. If a bracketed integer is appended, the Ith column of the array calculated by the compute is used. Users can also write code for their own compute styles and add them to LAMMPS. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “f_”, a fix ID must follow which has been previously defined in the input script. Fixes can generate per-atom or local quantities. See the individual fix page for details. Note that some fixes only produce their values on certain timesteps, which must be compatible with when compute reduce references the values, else an error results. If no bracketed integer is appended, the vector calculated by the fix is used. If a bracketed integer is appended, the Ith column of the array calculated by the fix is used. Users can also write code for their own fix style and add them to LAMMPS. See the discussion above for how I can be specified with a wildcard asterisk to effectively specify multiple values.

If a value begins with “v_”, a variable name must follow which has been previously defined in the input script. It must be an atom-style variable. Atom-style variables can reference thermodynamic keywords and various per-atom attributes, or invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of generating per-atom quantities to reduce.

If the replace keyword is used, two indices vec1 and vec2 are specified, where each index ranges from 1 to the # of input values. The replace keyword can only be used if the mode is min or max. It works as follows. A min/max is computed as usual on the vec2 input vector. The index N of that value within vec2 is also stored. Then, instead of performing a min/max on the vec1 input vector, the stored index is used to select the Nth element of the vec1 vector.

Thus, for example, if you wish to use this compute to find the bond with maximum stretch, you can do it as follows:

```
compute 1 all property/local batom1 batom2
compute 2 all bond/local dist
compute 3 all reduce max c_1[1] c_1[2] c_2 replace 1 3 replace 2 3
```
The first two input values in the compute reduce command are vectors with the IDs of the 2 atoms in each bond, using the compute property/local command. The last input value is bond distance, using the compute bond/local command. Instead of taking the max of the two atom ID vectors, which does not yield useful information in this context, the replace keywords will extract the atom IDs for the two atoms in the bond of maximum stretch. These atom IDs and the bond stretch will be printed with thermodynamic output.

If a single input is specified this compute produces a global scalar value. If multiple inputs are specified, this compute produces a global vector of values, the length of which is equal to the number of inputs specified.

As discussed below, for the sum, sumabs and sumsq modes, the value(s) produced by this compute are all “extensive”, meaning their value scales linearly with the number of atoms involved. If normalized values are desired, this compute can be accessed by the thermo_style custom command with thermo_modify norm yes set as an option. Or it can be accessed by a variable that divides by the appropriate atom count.

**18.83.4 Output info**

This compute calculates a global scalar if a single input value is specified or a global vector of length N where N is the number of inputs, and which can be accessed by indices 1 to N. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

All the scalar or vector values calculated by this compute are “intensive”, except when the sum, sumabs or sumsq modes are used on per-atom or local vectors, in which case the calculated values are “extensive”.

The scalar or vector values will be in whatever units the quantities being reduced are in.

### 18.84.2 Examples

```compute 1 all reduce/chunk mychunk min c_cluster```

### 18.84.3 Description

Define a calculation that reduces one or more per-atom vectors into per-chunk values. This can be useful for diagnostic output. Or when used in conjunction with the `compute chunk/spread/atom` command it can be used to create per-atom values that induce a new set of chunks with a second `compute chunk/atom` command. An example is given below.

In LAMMPS, chunks are collections of atoms defined by a `compute chunk/atom` command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the `compute chunk/atom` and `Howto chunk` doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

For each atom, this compute accesses its chunk ID from the specified `chunkID` compute. The per-atom value from an input contributes to a per-chunk value corresponding to the the chunk ID.

The reduction operation is specified by the `mode` setting and is performed over all the per-atom values from the atoms in each chunk. The *sum* option adds the pre-atom values to a per-chunk total. The *min* or *max* options find the minimum or maximum value of the per-atom values for each chunk.

Note that only atoms in the specified group contribute to the reduction operation. If the `chunkID` compute returns a 0 for the chunk ID of an atom (i.e. the atom is not in a chunk defined by the `compute chunk/atom` command), that atom will also not contribute to the reduction operation. An input that is a compute or fix may define its own group which affects the quantities it returns. For example, a compute with return a zero value for atoms that are not in the group specified for that compute.

Each listed input is operated on independently. Each input can be the result of a `compute` or `fix` or the evaluation of an atom-style `variable`.

Note that for values from a compute or fix, the bracketed index I can be specified using a wildcard asterisk with the index to effectively specify multiple values. This takes the form “*” or “*n” or “n*” or “m*n”. If N = the size of the vector (for `mode` = scalar) or the number of columns in the array (for `mode` = vector), then an asterisk with no numeric values means all indices from 1 to N. A leading asterisk means all indices from 1 to n (inclusive). A trailing asterisk means all indices from n to N (inclusive). A middle asterisk means all indices from m to n (inclusive).

Using a wildcard is the same as if the individual columns of the array had been listed one by one. E.g. these 2 compute reduce/chunk commands are equivalent, since the `compute property/chunk` command creates a per-atom array with 3 columns:
Here is an example of using this compute, in conjunction with the compute chunk/spread/atom command to identify self-assembled micelles. The commands below can be added to the examples/in.micelle script.

Imagine a collection of polymer chains or small molecules with hydrophobic end groups. All the hydrophobic (HP) atoms are assigned to a group called “phobic”.

These commands will assign a unique cluster ID to all HP atoms within a specified distance of each other. A cluster will contain all HP atoms in a single molecule, but also the HP atoms in nearby molecules, e.g. molecules that have clumped to form a micelle due to the attraction induced by the hydrophobicity. The output of the chunk/reduce command will be a cluster ID per chunk (molecule). Molecules with the same cluster ID are in the same micelle.

```
group phobic type 4  # specific to in.micelle model
compute cluster phobic cluster/atom 2.0
compute cmol all chunk/atom molecule
compute reduce phobic reduce/chunk cmol min c_cluster
```

This per-chunk info could be output in at least two ways:

```
fix 10 all ave/time 1000 1 1000 c_reduce file tmp.phobic mode vector
compute spread all chunk/spread/atom cmol c_reduce
dump 1 all custom 1000 tmp.dump id type mol x y z c_cluster c_spread
dump_modify 1 sort id
```

In the first case, each snapshot in the tmp.phobic file will contain one line per molecule. Molecules with the same value are in the same micelle. In the second case each dump snapshot contains all atoms, each with a final field with the cluster ID of the micelle that the HP atoms of that atom’s molecule belong to.

The result from compute chunk/spread/atom can be used to define a new set of chunks, where all the atoms in all the molecules in the same micelle are assigned to the same chunk, i.e. one chunk per micelle.

```
compute micelle all chunk/atom c_spread compress yes
```

Further analysis on a per-micelle basis can now be performed using any of the per-chunk computes listed on the Howto chunk doc page. E.g. count the number of atoms in each micelle, calculate its center or mass, shape (moments of inertia), radius of gyration, etc.

```
compute prop all property/chunk micelle count
fix 20 all ave/time 1000 1 1000 c_prop file tmp.micelle mode vector
```

Each snapshot in the tmp.micelle file will have one line per micelle with its count of atoms, plus a first line for a chunk with all the solvent atoms. By the time 50000 steps have elapsed there are a handful of large micelles.
18.84.4 Output info

This compute calculates a global vector if a single input value is specified, otherwise a global array is output. The number of columns in the array is the number of inputs provided. The length of the vector or the number of vector elements or array rows = the number of chunks $N_{chunk}$ as calculated by the specified `compute chunk/atom` command. The vector or array can be accessed by any command that uses global values from a compute as input. See the *How to output* page for an overview of LAMMPS output options.

The per-atom values for the vector or each column of the array will be in whatever *units* the corresponding input value is in. The vector or array values are “intensive”.

18.85 compute rigid/local command

18.85.1 Syntax

```
compute ID group-ID rigid/local rigidID input1 input2 ...
```

- ID, group-ID are documented in `compute` command
- `rigid/local` = style name of this compute command
- `rigidID` = ID of fix rigid/small command or one of its variants
- `input` = one or more rigid body attributes
  - possible attributes = `id`, `mol`, `mass`,
    `x, y, z, xu, yu, zu, ix, iy, iz`
    `vx, vy, vz, fx, fy, fz`,
    `omegax, omegay, omegaz`,
    `angmomx, angmomy, angmomz`,
    `quatw, quati,quatj, quatk`,
    `tqx, tqy, tqz`,
    `inertix, inertiy, inertiaz`
  - `id` = atom ID of atom within body which owns body properties
  - `mol` = molecule ID used to define body in `fix rigid/small` command
  - `mass` = total mass of body
  - `x,y,z` = center of mass coords of body
  - `xu,yu,zu` = unwrapped center of mass coords of body
  - `ix,iy,iz` = box image that the center of mass is in
  - `vx,vy,vz` = center of mass velocities
fx, fy, fz = force of center of mass
omega_x, omega_y, omega_z = angular velocity of body
angmom_x, angmom_y, angmom_z = angular momentum of body
quat_w, quat_i, quat_j, quat_k = quaternion components for body
torque_x, torque_y, torque_z = torque on body
inertia_x, inertia_y, inertia_z = diagonalized moments of inertia of body

18.85.2 Examples

```plaintext
compute 1 all rigid/local myRigid mol x y z
```

18.85.3 Description

Define a computation that simply stores rigid body attributes for rigid bodies defined by the `fix rigid/small` command or one of its NVE, NVT, NPT, NPH variants. The data is stored as local data so it can be accessed by other output commands that process local data, such as the `compute reduce` or `dump local` commands.

Note that this command only works with the `fix rigid/small` command or its variants, not the `fix rigid` command and its variants. The ID of the `fix rigid/small` command used to define rigid bodies must be specified as `rigidID`. The `fix rigid` command is typically used to define a handful of (potentially very large) rigid bodies. It outputs similar per-body information as this command directly from the fix as global data; see the `fix rigid` page for details.

The local data stored by this command is generated by looping over all the atoms owned on a processor. If the atom is not in the specified `group-ID` or is not part of a rigid body it is skipped. If it is not the atom within a body that is assigned to store the body information it is skipped (only one atom per body is so assigned). If it is the assigned atom, then the info for that body is output. This means that information for N bodies is generated. N may be less than the # of bodies defined by the `fix rigid` command, if the atoms in some bodies are not in the `group-ID`.

Note: Which atom in a body owns the body info is determined internal to LAMMPS; it’s the one nearest the geometric center of the body. Typically you should avoid this complication, by defining the group associated with this fix to include/exclude entire bodies.

Note that as atoms and bodies migrate from processor to processor, there will be no consistent ordering of the entries within the local vector or array from one timestep to the next.

Here is an example of how to use this compute to dump rigid body info to a file:

```plaintext
compute 1 all rigid/local myRigid mol x y z fx fy fz
```

This section explains the rigid body attributes that can be specified.

The `id` attribute is the atom-ID of the atom which owns the rigid body, which is assigned by the `fix rigid/small` command.

The `mol` attribute is the molecule ID of the rigid body. It should be the molecule ID which all of the atoms in the body belong to, since that is how the `fix rigid/small` command defines its rigid bodies.

The `mass` attribute is the total mass of the rigid body.

There are two options for outputting the coordinates of the center of mass (COM) of the body. The `x`, `y`, `z` attributes write the COM “unscaled”, in the appropriate distance units (Angstroms, sigma, etc). Use `xu`, `yu`, `zu` if you want the COM “unwrapped” by the image flags for each body. Unwrapped means that if the body COM has passed through

18.85. compute rigid/local command

1787
a periodic boundary one or more times, the value is generated what the COM coordinate would be if it had not been wrapped back into the periodic box.

The image flags for the body can be generated directly using the $ix$, $iy$, $iz$ attributes. For periodic dimensions, they specify which image of the simulation box the COM is considered to be in. An image of 0 means it is inside the box as defined. A value of 2 means add 2 box lengths to get the true value. A value of -1 means subtract 1 box length to get the true value. LAMMPS updates these flags as the rigid body COMs cross periodic boundaries during the simulation.

The vx, vy, vz, fx, fy, fz attributes are components of the COM velocity and force on the COM of the body.

The omegax, omegay, and omegaz attributes are the angular velocity components of the body in the system frame around its COM.

The angmomx, angmomy, and angmomz attributes are the angular momentum components of the body in the system frame around its COM.

The quatw, quati, quatj, and quatk attributes are the components of the 4-vector quaternion representing the orientation of the rigid body. See the set command for an explanation of the quaternion vector.

The tx, ty, tz attributes are components of the torque acting on the body around its COM.

The inertiaw, inertiax, inertiaz attributes are components of diagonalized inertia tensor for the body, i.e the 3 moments of inertia for the body around its principal axes, as computed internally by LAMMPS.

18.85.4 Output info

This compute calculates a local vector or local array depending on the number of keywords. The length of the vector or number of rows in the array is the number of rigid bodies. If a single keyword is specified, a local vector is produced. If two or more keywords are specified, a local array is produced where the number of columns = the number of keywords. The vector or array can be accessed by any command that uses local values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The vector or array values will be in whatever units the corresponding attribute is in:

- id,mol = unitless
- mass = mass units
- x,y,z and xy,yu,zu = distance units
- vx,vy,vz = velocity units
- fx, fy, fz = force units
- omegax, omegay, omegaz = radians/time units
- angmomx, angmomy, angmomz = mass*distance^2/time units
- quatw, quati, quatj, quatk = unitless
- tx, ty, tz = torque units
- inertiaw, inertiax, inertiaz = mass*distance^2 units
18.85.5 Restrictions

This compute is part of the RIGID package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

18.85.6 Related commands

18.86 compute saed command

18.86.1 Syntax

```
compute ID group-ID saed lambda type1 type2 ... typeN keyword value ...
```

- `ID`, `group-ID` are documented in `compute` command
- `saed` = style name of this compute command
- `lambda` = wavelength of incident radiation (length units)
- `type1 type2 ... typeN` = chemical symbol of each atom type (see valid options below)
- `zero` or more `keyword=value` pairs may be appended
- `keyword = Kmax or Zone or dR_Ewald or c or manual or echo`
  
  - `Kmax` value = Maximum distance explored from reciprocal space origin (inverse length units)
  - `Zone` values = z1 z2 z3
    - z1, z2, z3 = Zone axis of incident radiation. If z1=z2=z3=0 all reciprocal space will be meshed up to Kmax
  - `dR_Ewald` value = Thickness of Ewald sphere slice intercepting reciprocal space (inverse length units)
  - `c` values = c1 c2 c3
    - c1, c2, c3 = parameters to adjust the spacing of reciprocal lattice nodes in the h, k, and l directions respectively
  - `manual` = flag to use manual spacing of reciprocal lattice points based on the values of the c parameters
  - `echo` = flag to provide extra output for debugging purposes
18.86.2 Examples

| compute 1 all saed 0.0251 Al 0 Kmax 1.70 Zone 0 0 1 dR_Ewald 0.01 c 0.5 0.5 0.5 |

| fix saed/vtk 1 1 1 c_2 file Ni_000.saed |

18.86.3 Description

Define a computation that calculates electron diffraction intensity as described in (Coleman) on a mesh of reciprocal lattice nodes defined by the entire simulation domain (or manually) using simulated radiation of wavelength lambda.

The electron diffraction intensity I at each reciprocal lattice point is computed from the structure factor F using the equations:

\[ I = \frac{F^* F}{N} \]

\[ F(k) = \sum_{j=1}^{N} f_j(\theta) \exp(2\pi i k \cdot r_j) \]

Here, K is the location of the reciprocal lattice node, \( r_j \) is the position of each atom, \( f_j \) are atomic scattering factors. Diffraction intensities are calculated on a three-dimensional mesh of reciprocal lattice nodes. The mesh spacing is defined either (a) by the entire simulation domain or (b) manually using selected values as shown in the 2D diagram below.

For a mesh defined by the simulation domain, a rectilinear grid is constructed with spacing \( c \times \text{inv}(A) \) along each reciprocal lattice axis. Where A are the vectors corresponding to the edges of the simulation cell. If one or two directions has non-periodic boundary conditions, then the spacing in these directions is defined from the average of the (inversed) box lengths with periodic boundary conditions. Meshes defined by the simulation domain must contain at least one periodic boundary.

If the manual flag is included, the mesh of reciprocal lattice nodes will defined using the \( c \) values for the spacing along each reciprocal lattice axis. Note that manual mapping of the reciprocal space mesh is good for comparing diffraction results from multiple simulations; however it can reduce the likelihood that Bragg reflections will be satisfied unless small spacing parameters <0.05 Å are implemented. Meshes with manual spacing do not require a periodic boundary.

The limits of the reciprocal lattice mesh are determined by the use of the \( K_{\text{max}} \), \( \text{Zone} \), and \( dR_{\text{Ewald}} \) parameters. The rectilinear mesh created about the origin of reciprocal space is terminated at the boundary of a sphere of radius \( K_{\text{max}} \) centered at the origin. If \( \text{Zone} \) parameters \( z_1 = z_2 = z_3 = 0 \) are used, diffraction intensities are computed throughout the entire spherical volume - note this can greatly increase the cost of computation. Otherwise, \( \text{Zone} \) parameters will denote the \( z_1 = h \), \( z_2 = k \), and \( z_3 = l \) (in a global sense) zone axis of an intersecting Ewald sphere. Diffraction intensities will only be computed at the intersection of the reciprocal lattice mesh and a \( dR_{\text{Ewald}} \) thick surface of the Ewald sphere. See the example 3D intensity data and the intersection of a [010] zone axis in the below image.
The atomic scattering factors, $f_j$, accounts for the reduction in diffraction intensity due to Compton scattering. Compute saed uses analytical approximations of the atomic scattering factors that vary for each atom type (type1 type2 ... typeN) and angle of diffraction. The analytic approximation is computed using the formula \( (Brown) \):

$$f_j \left( \frac{\sin(\theta)}{\lambda} \right) = \sum_i a_i \exp \left( -b_i \frac{\sin^2(\theta)}{\lambda^2} \right)$$

Coefficients parameterized by \( (Fox) \) are assigned for each atom type designating the chemical symbol and charge of each atom type. Valid chemical symbols for compute saed are:

| H | He | Li | Be | B | C | N | O | F | Ne | Na | Mg | Al | Si | P | S | Cl | Ar | K | Ca |
|---|----|----|----|---|---|----|---|---|----|----|----|----|----|---|---|---|----|---|---|---|
| Sc | Ti | V | Cr | Mn | Fe | Co | Ni | Cu | Zn | Ga | Ge | As | Se | Br | Kr | Rb | Sr | Y | Zr |
| Nb | Mo | Tc | Ru | Rh | Pd | Ag | Cd | In | Sn | Sb | Te | I | Xe | Cs | Ba | La | Ce | Pr | Nd |
| Pm | Sm | Eu | Gd | Tb | Dy | Ho | Er | Tm | Yb | Lu | Hf | Ta | W | Re | Os | Ir | Pt | Au | Hg |
| Tl | Pb | Bi | Po | At | Rn | Fr | Ra | Ac | Th | Pa | U | Np | Pu | Am | Cm | Bk | Cf | --- | --- |

If the *echo* keyword is specified, compute saed will provide extra reporting information to the screen.
18.86.4 Output info

This compute calculates a global vector. The length of the vector is the number of reciprocal lattice nodes that are explored by the mesh. The entries of the global vector are the computed diffraction intensities as described above.

The vector can be accessed by any command that uses global values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

All array values calculated by this compute are “intensive”.

18.86.5 Restrictions

This compute is part of the DIFFRACTION package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

The compute_saed command does not work for triclinic cells.

18.86.6 Related commands

fix saed_vtk, compute xrd

18.86.7 Default

The option defaults are Kmax = 1.70, Zone 1 0 0, c 1 1 1, dR_Ewald = 0.01.

18.87 compute slice command

18.87.1 Syntax

```plaintext
compute ID group-ID slice Nstart Nstop Nskip input1 input2 ...
```

- ID, group-ID are documented in compute command
- slice = style name of this compute command
- Nstart = starting index within input vector(s)
- Nstop = stopping index within input vector(s)
- Nskip = extract every Nskip elements from input vector(s)
- input = c_ID, c_ID[N], f_ID, f_ID[N]
c_ID = global vector calculated by a compute with ID
f_ID = global vector calculated by a fix with ID
v_name = vector calculated by a vector-style variable with name

c_ID[I] = Ith column of global array calculated by a compute with ID
f_ID[I] = Ith column of global array calculated by a fix with ID

18.87.2 Examples

```
compute 1 all slice 1 100 10 c_msdmol[4]
compute 1 all slice 301 400 1 c_msdmol[4] v_myVec
```

18.87.3 Description

Define a calculation that “slices” one or more vector inputs into smaller vectors, one per listed input. The inputs can be global quantities; they cannot be per-atom or local quantities. *Computes* and *fixes* and vector-style *variables* can generate such global quantities. The group specified with this command is ignored.

The values extracted from the input vector(s) are determined by the $N_{start}$, $N_{stop}$, and $N_{skip}$ parameters. The elements of an input vector of length $N$ are indexed from 1 to $N$. Starting at element $N_{start}$, every $M$th element is extracted, where $M = N_{skip}$, until element $N_{stop}$ is reached. The extracted quantities are stored as a vector, which is typically shorter than the input vector.

Each listed input is operated on independently to produce one output vector. Each listed input must be a global vector or column of a global array calculated by another *compute* or *fix*.

If an input value begins with “c_”, a compute ID must follow which has been previously defined in the input script and which generates a global vector or array. See the individual *compute* doc page for details. If no bracketed integer is appended, the vector calculated by the compute is used. If a bracketed integer is appended, the Ith column of the array calculated by the compute is used. Users can also write code for their own compute styles and *add them to LAMMPS*.

If a value begins with “f_”, a fix ID must follow which has been previously defined in the input script and which generates a global vector or array. See the individual *fix* page for details. Note that some fixes only produce their values on certain timesteps, which must be compatible with when compute slice references the values, else an error results. If no bracketed integer is appended, the vector calculated by the fix is used. If a bracketed integer is appended, the Ith column of the array calculated by the fix is used. Users can also write code for their own fix style and *add them to LAMMPS*.

If an input value begins with “v_”, a variable name must follow which has been previously defined in the input script. Only vector-style variables can be referenced. See the *variable* command for details. Note that variables of style *vector* define a formula which can reference individual atom properties or thermodynamic keywords, or they can invoke other computes, fixes, or variables when they are evaluated, so this is a very general means of specifying quantities to slice.

If a single input is specified this compute produces a global vector, even if the length of the vector is 1. If multiple inputs are specified, then a global array of values is produced, with the number of columns equal to the number of inputs specified.
18.87.4 Output info

This compute calculates a global vector if a single input value is specified or a global array with N columns where N is the number of inputs. The length of the vector or the number of rows in the array is equal to the number of values extracted from each input vector. These values can be used by any command that uses global vector or array values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The vector or array values calculated by this compute are simply copies of values generated by computes or fixes or variables that are input vectors to this compute. If there is a single input vector of intensive and/or extensive values, then each value in the vector of values calculated by this compute will be “intensive” or “extensive”, depending on the corresponding input value. If there are multiple input vectors, and all the values in them are intensive, then the array values calculated by this compute are “intensive”. If there are multiple input vectors, and any value in them is extensive, then the array values calculated by this compute are “extensive”. Values produced by a variable are treated as intensive.

The vector or array values will be in whatever units the input quantities are in.

- ID, group-ID are documented in compute command
- smd/tlsph/defgrad = style name of this compute command
18.95.2 Examples

```compute  1 all  smd/tlsph/defgrad```

18.95.3 Description

Define a computation that calculates the deformation gradient. It is only meaningful for particles which interact according to the Total-Lagrangian SPH pair style.

See this PDF guide to use Smooth Mach Dynamics in LAMMPS.

18.95.4 Output info

This compute outputs a per-particle vector of vectors (tensors), which can be accessed by any command that uses per-particle values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The per-particle vector values will be given dimensionless. See units. The per-particle vector has 10 entries. The first nine entries correspond to the xx, xy, xz, yx, yy, yz, zx, zy, zz components of the asymmetric deformation gradient tensor. The tenth entry is the determinant of the deformation gradient.

18.95.5 Restrictions

This compute is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info. This compute can only be used for particles which interact via the total Lagrangian SPH pair style.

- ID, group-ID are documented in compute command
- `smd/tlsph/dt` = style name of this compute command
18.96.2 Examples

```
compute 1 all smd/tlsph/dt
```

18.96.3 Description

Define a computation that outputs the CFL-stable time increment per particle. This time increment is essentially given by the speed of sound, divided by the SPH smoothing length. Because both the speed of sound and the smoothing length typically change during the course of a simulation, the stable time increment needs to be re-computed every time step. This calculation is performed automatically in the relevant SPH pair styles and this compute only serves to make the stable time increment accessible for output purposes.

See this PDF guide to using Smooth Mach Dynamics in LAMMPS.

18.96.4 Output info

This compute calculates a per-particle vector, which can be accessed by any command that uses per-particle values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The per-particle values will be given in units of time.

18.96.5 Restrictions

This compute is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This compute can only be used for particles interacting with the Total-Lagrangian SPH pair style.

18.98.2 Examples

```
compute 1 all smd/tlsph/shape
```

18.98.3 Description

Define a computation that outputs the current shape of the volume associated with a particle as a rotated ellipsoid. It is only meaningful for particles which interact according to the Total-Lagrangian SPH pair style.

See this PDF guide to use Smooth Mach Dynamics in LAMMPS.

18.98.4 Output info

This compute calculates a per-particle vector of vectors, which can be accessed by any command that uses per-particle values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The per-particle vector has 7 entries. The first three entries correspond to the lengths of the ellipsoid’s axes and have units of length. These axis values are computed as the contact radius times the xx, yy, or zz components of the Green-Lagrange strain tensor associated with the particle. The next 4 values are quaternions (order: q, x, y, z) which describe the spatial rotation of the particle relative to its initial state.

18.98.5 Restrictions

This compute is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This quantity will be computed only for particles which interact with the Total-Lagrangian SPH pair style.

```

18.102.3 Description

Define a computation that returns the coordinates of the vertices corresponding to the triangle-elements of a mesh created by the `fix smd/wall_surface`.

See this PDF guide to using Smooth Mach Dynamics in LAMMPS.

18.102.4 Output info

This compute returns a per-particle vector of vectors, which can be accessed by any command that uses per-particle values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The per-particle vector has nine entries, (x1/y1/z1), (x2/y2/z2), and (x3/y3/z3) corresponding to the first, second, and third vertex of each triangle.

It is only meaningful to use this compute for a group of particles which is created via the `fix smd/wall_surface` command.

The output of this compute can be used with the dump2vtk_tris tool to generate a VTK representation of the smd/wall_surface mesh for visualization purposes.

The values will be given in units of distance.

### 18.112.3 Description

Define a computation that calculates a set of quantities related to the bispectrum components of the atoms in a group. These computes are used primarily for calculating the dependence of energy, force, and stress components on the linear coefficients in the `snap pair_style`, which is useful when training a SNAP potential to match target data.

Bispectrum components of an atom are order parameters characterizing the radial and angular distribution of neighbor atoms. The detailed mathematical definition is given in the paper by Thompson et al. *(Thompson)*

The position of a neighbor atom $i'$ relative to a central atom $i$ is a point within the 3D ball of radius $R_{ii'} = \text{rcutfac}(R_i + R_i')$

Bartok et al. *(Bartok)*, proposed mapping this 3D ball onto the 3-sphere, the surface of the unit ball in a four-dimensional space. The radial distance $r$ within $R_{ii'}$ is mapped on to a third polar angle $\theta_0$ defined by,

$$
\theta_0 = \frac{r - r_{\text{min}0}}{R_{ii'} - r_{\text{min}0}} \pi
$$

In this way, all possible neighbor positions are mapped on to a subset of the 3-sphere. Points south of the latitude $\theta_0 = \frac{r_{\text{fac}0}}{\pi}$ are excluded.

The natural basis for functions on the 3-sphere is formed by the representatives of $SU(2)$, the matrices $U^j_{m, m'}(\theta, \phi, \theta_0)$. These functions are better known as $D^j_{m, m'}$, the elements of the Wigner D-matrices *(Meremianin, Varshalovich, Mason)* The density of neighbors on the 3-sphere can be written as a sum of Dirac-delta functions, one for each neighbor, weighted by species and radial distance. Expanding this density function as a generalized Fourier series in the basis functions, we can write each Fourier coefficient as

$$
u^j_{m, m'} = U^j_{m, m'}(0, 0, 0) + \sum_{R_{ii'} < R_{ii'}} f_c(r_{ii'}) w_{m, m'} U^j_{m, m'}(\theta_0, \theta, \phi)
$$

The $w_{m, m'}$ neighbor weights are dimensionless numbers that depend on $\mu_{i'}$, the SNAP element of atom $i'$, while the central atom is arbitrarily assigned a unit weight. The function $f_c(r)$ ensures that the contribution of each neighbor atom goes smoothly to zero at $R_{ii'}$:

$$
f_c(r) = \frac{1}{2} (\cos(\pi \frac{r - r_{\text{min}0}}{R_{ii'} - r_{\text{min}0}}) + 1), r \leq R_{ii'}
$$

$$
e=0, r > R_{ii'}
$$

The expansion coefficients $\nu^j_{m, m'}$ are complex-valued and they are not directly useful as descriptors, because they are not invariant under rotation of the polar coordinate frame. However, the following scalar triple products of expansion coefficients can be shown to be real-valued and invariant under rotation *(Bartok)*,

$$
B_{j_1, j_2, j} = \sum_{m_1, m'_1 = -j_1}^{j_1} \sum_{m_2, m'_2 = -j_2}^{j_2} \sum_{m, m' = -j}^{j} (\nu^j_{m, m'})^* H_{j_1 m_1 m'_1}^{j_1 m_1} \nu^j_{m_2, m'_2} H_{j_2 m_2 m'_2}^{j_2 m_2}
$$

18.112. compute snap command
The constants $H_{j_1 m_1, j_2 m_2}^{j m}$ are coupling coefficients, analogous to Clebsch-Gordan coefficients for rotations on the 2-sphere. These invariants are the components of the bispectrum and these are the quantities calculated by the compute sna/atom. They characterize the strength of density correlations at three points on the 3-sphere. The $j_2=0$ subset form the power spectrum, which characterizes the correlations of two points. The lowest-order components describe the coarsest features of the density function, while higher-order components reflect finer detail. Each bispectrum component contains terms that depend on the positions of up to 4 atoms (3 neighbors and the central atom).

Compute snad/atom calculates the derivative of the bispectrum components summed separately for each LAMMPS atom type:

$$\sum_{i' \in I} \frac{\partial B_{j_1 j_2 j_3}^{j m^i}}{\partial r_i}$$

The sum is over all atoms $i'$ of atom type $I$. For each atom $i$, this compute evaluates the above expression for each direction, each atom type, and each bispectrum component. See section below on output for a detailed explanation.

Compute snav/atom calculates the virial contribution due to the derivatives:

$$-r_i \otimes \sum_{i' \in I} \frac{\partial B_{j_1 j_2 j_3}^{j m^i}}{\partial r_i}$$

Again, the sum is over all atoms $i'$ of atom type $I$. For each atom $i$, this compute evaluates the above expression for each of the six virial components, each atom type, and each bispectrum component. See section below on output for a detailed explanation.

Compute snap calculates a global array containing information related to all three of the above per-atom computes sna/atom, snad/atom, and snav/atom. The first row of the array contains the summation of sna/atom over all atoms, but broken out by type. The last six rows of the array contain the summation of snav/atom over all atoms, broken out by type. In between these are $3N$ rows containing the same values computed by snad/atom (these are already summed over all atoms and broken out by type). The element in the last column of each row contains the potential energy, force, or stress, according to the row. These quantities correspond to the user-specified reference potential that must be subtracted from the target data when fitting SNAP. The potential energy calculation uses the built in compute thermo_pe. The stress calculation uses a compute called snap_press that is automatically created behind the scenes, according to the following command:

```
compute snap_press all pressure NULL virial
```

See section below on output for a detailed explanation of the data layout in the global array.

The value of all bispectrum components will be zero for atoms not in the group. Neighbor atoms not in the group do not contribute to the bispectrum of atoms in the group.

The neighbor list needed to compute this quantity is constructed each time the calculation is performed (i.e. each time a snapshot of atoms is dumped). Thus it can be inefficient to compute/dump this quantity too frequently.

The argument rcutfac is a scale factor that controls the ratio of atomic radius to radial cutoff distance.

The argument rfac0 and the optional keyword rmin0 define the linear mapping from radial distance to polar angle $\theta_0$ on the 3-sphere, given above.

The argument twojmax defines which bispectrum components are generated. See section below on output for a detailed explanation of the number of bispectrum components and the ordered in which they are listed.

The keyword switchflag can be used to turn off the switching function $f_c(r)$.

The keyword bzeroflag determines whether or not $B_0$, the bispectrum components of an atom with no neighbors, are subtracted from the calculated bispectrum components. This optional keyword normally only affects compute sna/atom. However, when quadraticflag is on, it also affects snad/atom and snav/atom.
The keyword \textit{quadraticflag} determines whether or not the quadratic combinations of bispectrum quantities are generated. These are formed by taking the outer product of the vector of bispectrum components with itself. See section below on output for a detailed explanation of the number of quadratic terms and the ordered in which they are listed.

The keyword \textit{chem} activates the explicit multi-element variant of the SNAP bispectrum components. The argument \textit{nelements} specifies the number of SNAP elements that will be handled. This is followed by \textit{elementlist}, a list of integers of length \textit{nypes}, with values in the range \([0, \text{nelements})\), which maps each LAMMPS type to one of the SNAP elements. Note that multiple LAMMPS types can be mapped to the same element, and some elements may be mapped by no LAMMPS type. However, in typical use cases (training SNAP potentials) the mapping from LAMMPS types to elements is one-to-one.

The explicit multi-element variant invoked by the \textit{chem} keyword partitions the density of neighbors into partial densities for each chemical element. This is described in detail in the paper by Cusentino et al. The bispectrum components are indexed on ordered triplets of elements:

\[
B^{\kappa\lambda\mu}_{j_1,j_2,j_3} = \sum_{m_{1}^{-},m_{1}^{+}=-j_{1}}^{j_{1}} \sum_{m_{2}^{-},m_{2}^{+}=-j_{2}}^{j_{2}} \sum_{m_{3}^{-},m_{3}^{+}=-j_{3}}^{j_{3}} (u_{j,m,m}^{\mu})^{*} H_{j_{1}m_{1}m_{1}^{+}}^{j_{2}m_{2}m_{2}^{+}} w_{j_{1},m_{1},m_{1}^{+}}^{\kappa} w_{j_{2},m_{2},m_{2}^{+}}^{\lambda} w_{j_{3},m_{3},m_{3}^{+}}^{\mu}
\]

where \(w_{j,m,m}^{\mu}\) is an expansion coefficient for the partial density of neighbors of element \(\mu\)

\[
w_{j,m,m}^{\mu} = w_{\mu,i}^{\text{self}} U_{j,m,m}^{\mu} (0,0,0) + \sum_{r_{ii'}<R_{ii'}} \delta_{\mu,i} f_{c}(r_{ii'}) w_{\mu,i}^{\text{self}} U_{j,m,m}^{\mu} (\theta, \theta, \phi)
\]

where \(w_{\mu,i}^{\text{self}}\) is the self-contribution, which is either 1 or 0 (see keyword \textit{wselfallflag} below), \(\delta_{\mu,i}\) indicates that the sum is only over neighbor atoms of element \(\mu\), and all other quantities are the same as those appearing in the original equation for \(w_{m,m}^{\mu}\) given above.

The keyword \textit{wselfallflag} defines the rule used for the self-contribution. If \textit{wselfallflag} is on, then \(w_{\mu,i}^{\text{self}} = 1\). If it is off then \(w_{\mu,i}^{\text{self}} = 0\), except in the case of \(\mu = \mu\), when \(w_{\mu,i}^{\text{self}} = 1\). When the \textit{chem} keyword is not used, this keyword has no effect.

The keyword \textit{bnormflag} determines whether or not the bispectrum component \(B_{j_{1},j_{2},j_{3}}\) is divided by a factor of \(2j + 1\). This normalization simplifies force calculations because of the following symmetry relation

\[
\frac{B_{j_{1},j_{2},j_{3}}}{2j + 1} = \frac{B_{j_{1},j_{2},j_{1}}}{2j_{1} + 1} = \frac{B_{j_{2},j_{1},j_{2}}}{2j_{2} + 1}
\]

This option is typically used in conjunction with the \textit{chem} keyword, and LAMMPS will generate a warning if both \textit{chem} and \textit{bnormflag} are not both set or not both unset.

The keyword \textit{bikflag} determines whether or not to expand the bispectrum rows of the global array returned by compute snap. If \textit{bikflag} is set to \(l\) then the bispectrum row, which is typically the per-atom bispectrum descriptors \(B_{i,k}\) summed over all atoms \(i\) to produce \(B_{k}\), becomes bispectrum rows equal to the number of atoms. Thus, the resulting bispectrum rows are \(B_{i,k}\) instead of just \(B_{k}\). In this case, the entries in the final column for these rows are set to zero.

The keyword \textit{switchinnerflag} with value 1 activates an additional radial switching function similar to \(f_{c}(r)\) above, but acting to switch off smoothly contributions from neighbor atoms at short separation distances. This is useful when SNAP is used in combination with a simple repulsive potential. For a neighbor atom at distance \(r\), its contribution is scaled by a multiplicative factor \(f_{\text{inner}}(r)\) defined as follows:

\[
f_{\text{inner}}(r) = \begin{cases} 
0, & r \leq S_{\text{inner}} - D_{\text{inner}} \\
\frac{1}{2}(1 - \cos(\pi \frac{1 + \frac{r - S_{\text{inner}}}{D_{\text{inner}}}}{2})), & S_{\text{inner}} - D_{\text{inner}} < r \leq S_{\text{inner}} + D_{\text{inner}} \\
1, & r > S_{\text{inner}} + D_{\text{inner}}
\end{cases}
\]

where the switching region is centered at \(S_{\text{inner}}\) and it extends a distance \(D_{\text{inner}}\) to the left and to the right of this. With this option, additional keywords \textit{sinner} and \textit{dinner} must be used, each followed by \textit{nypes} values for \(S_{\text{inner}}\) and

18.112. \textit{compute snap command}
When the central atom and the neighbor atom have different types, the values of \( S_{inner} \) and \( D_{inner} \) are the arithmetic means of the values for both types.

**Note:** If you have a bonded system, then the settings of `special_bonds` command can remove pairwise interactions between atoms in the same bond, angle, or dihedral. This is the default setting for the `special_bonds` command, and means those pairwise interactions do not appear in the neighbor list. Because this fix uses the neighbor list, it also means those pairs will not be included in the calculation. One way to get around this, is to write a dump file, and use the `rerun` command to compute the bispectrum components for snapshots in the dump file. The rerun script can use a `special_bonds` command that includes all pairs in the neighbor list.

### 18.112.4 Output info

Compute `sna/atom` calculates a per-atom array, each column corresponding to a particular bispectrum component. The total number of columns and the identity of the bispectrum component contained in each column depend of the value of `twojmax`, as described by the following piece of python code:

```python
for j1 in range(0,twojmax+1):
    for j2 in range(0,j1+1):
        for j in range(j1-j2,min(twojmax,j1+j2)+1,2):
            if (j>=j1): print j1/2.,j2/2.,j/2.
```

For even `twojmax = 2(m-1)`, \( K = m(m+1)(2m+1)/6 \), the \( m \)-th pyramidal number. For odd `twojmax = 2m-1`, \( K = m(m+1)(m+2)/3 \), twice the \( m \)-th tetrahedral number.

**Note:** the `diagonal` keyword allowing other possible choices for the number of bispectrum components was removed in 2019, since all potentials use the value of 3, corresponding to the above set of bispectrum components.

Compute `snad/atom` evaluates a per-atom array. The columns are arranged into `ntypes` blocks, listed in order of atom type \( I \). Each block contains three sub-blocks corresponding to the \( x \), \( y \), and \( z \) components of the atom position. Each of these sub-blocks contains \( K \) columns for the \( K \) bispectrum components, the same as for compute `sna/atom`.

Compute `snav/atom` evaluates a per-atom array. The columns are arranged into `ntypes` blocks, listed in order of atom type \( I \). Each block contains six sub-blocks corresponding to the \( xx \), \( yy \), \( zz \), \( yz \), \( xz \), and \( xy \) components of the virial tensor in Voigt notation. Each of these sub-blocks contains \( K \) columns for the \( K \) bispectrum components, the same as for compute `sna/atom`.

Compute `snap` evaluates a global array. The columns are arranged into `ntypes` blocks, listed in order of atom type \( I \). Each block contains one column for each bispectrum component, the same as for compute `sna/atom`. A final column contains the corresponding energy, force component on an atom, or virial stress component. The rows of the array appear in the following order:

- 1 row: `sna/atom` quantities summed for all atoms of type \( I \)
- \( 3*N \) rows: `snad/atom` quantities, with derivatives w.r.t. \( x \), \( y \), and \( z \) coordinate of atom \( i \) appearing in consecutive rows. The atoms are sorted based on atom ID.
- 6 rows: `snav/atom` quantities summed for all atoms of type \( I \)

For example, if \( K =50 \) and \( ntypes=1 \), the number of columns in the per-atom arrays generated by `sna/atom`, `snad/atom`, and `snav/atom` are 30, 90, and 180, respectively. With `quadratic value=1`, the numbers of columns are 930, 2790, and 5580, respectively. The number of columns in the global array generated by `snap` are 31, and 931, respectively, while the number of rows is \( 1+3*N+6 \), where \( N \) is the total number of atoms.
If the quadratic keyword value is set to 1, then additional columns are generated, corresponding to the products of all distinct pairs of bispectrum components. If the number of bispectrum components is $K$, then the number of distinct pairs is $K(K+1)/2$. For compute snad/atom these columns are appended to existing $K$ columns. The ordering of quadratic terms is upper-triangular, $(1,1),(1,2),\ldots,(1,K),(2,1),\ldots,(K-1,K-1),(K-1,K),(K,K)$. For computes snad/atom and snav/atom each set of $K(K+1)/2$ additional columns is inserted directly after each of sub-block of linear terms i.e. linear and quadratic terms are contiguous. So the nesting order from inside to outside is bispectrum component, linear then quadratic, vector/tensor component, type.

If the chem keyword is used, then the data is arranged into $N^3_{\text{elem}}$ sub-blocks, each sub-block corresponding to a particular chemical labeling $\kappa\lambda\mu$ with the last label changing fastest. Each sub-block contains $K$ bispectrum components. For the purposes of handling contributions to force, virial, and quadratic combinations, these $N^3_{\text{elem}}$ sub-blocks are treated as a single block of $KN^3_{\text{elem}}$ columns.

These values can be accessed by any command that uses per-atom values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options. To see how this command can be used within a Python workflow to train SNAP potentials, see the examples in FitSNAP.

### 18.112.5 Restrictions

These computes are part of the ML-SNAP package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

### 18.112.6 Related commands

pair_style snap

### 18.112.7 Default

The optional keyword defaults are $rmin0=0$, switchflag = 1, bzeroflag = 1, quadraticflag = 0, bnormflag = 0, wselfallflag = 0, switchinnerflag = 0.

18.113 compute sph/e/atom command

18.113.1 Syntax

compute ID group-ID sph/e/atom

- ID, group-ID are documented in compute command
- sph/e/atom = style name of this compute command

18.113.2 Examples

compute 1 all sph/e/atom

18.113.3 Description

Define a computation that calculates the per-atom internal energy for each atom in a group.

The internal energy is the energy associated with the internal degrees of freedom of an SPH particle, i.e. a Smooth-Particle Hydrodynamics particle.

See this PDF guide to using SPH in LAMMPS.

The value of the internal energy will be 0.0 for atoms not in the specified compute group.

18.113.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The per-atom vector values will be in energy units.

18.113.5 Restrictions

This compute is part of the SPH package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

```

18.114.3 Description

Define a computation that calculates the per-atom SPH density for each atom in a group, i.e. a Smooth-Particle Hydrodynamics density.

The SPH density is the mass density of an SPH particle, calculated by kernel function interpolation using “pair style sph/rhosum”.

See this PDF guide to using SPH in LAMMPS.

The value of the SPH density will be 0.0 for atoms not in the specified compute group.

18.114.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the `Howto output` page for an overview of LAMMPS output options.

The per-atom vector values will be in mass/volume units.

18.114.5 Restrictions

This compute is part of the SPH package. It is only enabled if LAMMPS was built with that package. See the `Build package` page for more info.

18.115.2 Examples

```
compute 1 all sph/t/atom
```

18.115.3 Description

Define a computation that calculates the per-atom internal temperature for each atom in a group.

The internal temperature is the ratio of internal energy over the heat capacity associated with the internal degrees of freedom of an SPH particles, i.e. a Smooth-Particle Hydrodynamics particle.

\[ T_{int} = \frac{E_{int}}{C_{V, int}} \]

See this PDF guide to using SPH in LAMMPS.

The value of the internal energy will be 0.0 for atoms not in the specified compute group.

18.115.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The per-atom vector values will be in temperature units.
18.115.5 Restrictions

18.116 compute spin command

18.116.1 Syntax

```
compute ID group-ID spin
```

- ID, group-ID are documented in compute command
- spin = style name of this compute command

18.116.2 Examples

```
compute out_mag all spin
```

18.116.3 Description

Define a computation that calculates magnetic quantities for a system of atoms having spins.

This compute calculates the following 6 magnetic quantities:

- the three first quantities are the x,y and z coordinates of the total magnetization,
- the fourth quantity is the norm of the total magnetization,
- The fifth quantity is the magnetic energy (in eV),
- The sixth one is referred to as the spin temperature, according to the work of *(Nurdin).*

The simplest way to output the results of the compute spin calculation is to define some of the quantities as variables, and to use the thermo and thermo_style commands, for example:

```
compute out_mag all spin
variable mag_z equal c_out_mag[3]
variable mag_norm equal c_out_mag[4]
variable temp_mag equal c_out_mag[6]
```
thermo
thermo_style

This series of commands evaluates the total magnetization along z, the norm of the total magnetization, and the magnetic temperature. Three variables are assigned to those quantities. The thermo and thermo_style commands print them every 10 timesteps.

18.116.4 Output info

The array values are “intensive”. The array values will be in metal units (units).

18.116.5 Restrictions

The spin compute is part of the SPIN package. This compute is only enabled if LAMMPS was built with this package. See the Build package page for more info. The atom_style has to be “spin” for this compute to be valid.

18.118.3 Description

Define a computation that computes per-atom stress tensor for each atom in a group. In case of compute stress/atom, the tensor for each atom is symmetric with 6 components and is stored as a 6-element vector in the following order: \( xx, yy, zz, xy, xz, yz \). In case of compute centroid/stress/atom, the tensor for each atom is asymmetric with 9 components and is stored as a 9-element vector in the following order: \( xx, yy, zz, xy, xz, yz, yx, zx, zy \). See the compute pressure command if you want the stress tensor (pressure) of the entire system.

The stress tensor for atom \( I \) is given by the following formula, where \( a \) and \( b \) take on values \( x, y, z \) to generate the components of the tensor:

\[
S_{ab} = -mv_au_b - W_{ab}
\]

The first term is a kinetic energy contribution for atom \( I \). See details below on how the specified temp-ID can affect the velocities used in this calculation. The second term is the virial contribution due to intra and intermolecular interactions, where the exact computation details are determined by the compute style.

In case of compute stress/atom, the virial contribution is:

\[
W_{ab} = \frac{1}{2} \sum_{n=1}^{N_p} (r_{1a}F_{1b} + r_{2a}F_{2b}) + \frac{1}{2} \sum_{n=1}^{N_b} (r_{1b}F_{1a} + r_{2b}F_{2a})
\]

\[
+ \frac{1}{3} \sum_{n=1}^{N_a} (r_{1a}F_{1b} + r_{2a}F_{2b} + r_{3a}F_{3b}) + \frac{1}{4} \sum_{n=1}^{N_d} (r_{1a}F_{1b} + r_{2a}F_{2b} + r_{3a}F_{3b} + r_{4a}F_{4b})
\]

\[
+ \frac{1}{4} \sum_{n=1}^{N_i} (r_{1a}F_{1b} + r_{2a}F_{2b} + r_{3a}F_{3b} + r_{4a}F_{4b}) + \text{KSpace}(r_{ia}, F_{ib}) + \sum_{n=1}^{N_f} r_{ia}F_{ib}
\]

The first term is a pairwise energy contribution where \( n \) loops over the \( N_p \) neighbors of atom \( I \), \( r_1 \) and \( r_2 \) are the positions of the 2 atoms in the pairwise interaction, and \( F_1 \) and \( F_2 \) are the forces on the 2 atoms resulting from the pairwise interaction. The second term is a bond contribution of similar form for the \( N_b \) bonds which atom \( I \) is part of. There are similar terms for the \( N_a \) angle, \( N_d \) dihedral, and \( N_i \) improper interactions atom \( I \) is part of. There is also a term for the KSpace contribution from long-range Coulombic interactions, if defined. Finally, there is a term for the \( N_f \) fixes that apply internal constraint forces to atom \( I \). Currently, only the fix shake and fix rigid commands contribute to this term. As the coefficients in the formula imply, a virial contribution produced by a small set of atoms (e.g. 4 atoms in a dihedral or 3 atoms in a Tersoff 3-body interaction) is assigned in equal portions to each atom in the set. E.g. 1/4 of the dihedral virial to each of the 4 atoms, or 1/3 of the fix virial due to SHAKE constraints applied to atoms in a water molecule via the fix shake command. As an exception, the virial contribution from constraint forces in fix rigid on each atom is computed from the constraint force acting on the corresponding atom and its position, i.e. the total virial is not equally distributed.

In case of compute centroid/stress/atom, the virial contribution is:

\[
W_{ab} = \sum_{n=1}^{N_p} r_{10a}F_{1b} + \sum_{n=1}^{N_b} r_{10b}F_{1a} + \sum_{n=1}^{N_a} r_{10a}F_{1b} + \sum_{n=1}^{N_d} r_{10a}F_{1b} + \sum_{n=1}^{N_i} r_{10a}F_{1b}
\]

\[
+ \text{KSpace}(r_{ia}, F_{ib}) + \sum_{n=1}^{N_f} r_{ia}F_{ib}
\]
As with compute stress/atom, the first, second, third, fourth and fifth terms are pairwise, bond, angle, dihedral and improper contributions, but instead of assigning the virial contribution equally to each atom, only the force $F_I$ acting on atom $I$ due to the interaction and the relative position $r_{10}$ of the atom $I$ to the geometric center of the interacting atoms, i.e. centroid, is used. As the geometric center is different for each interaction, the $r_{10}$ also differs. The sixth term, Kspace contribution, is computed identically to compute stress/atom. The seventh term is handed differently depending on if the constraint forces are due to fix shake or fix rigid. In case of SHAKE constraints, each distance constraint is handed as a pairwise interaction. E.g. in case of a water molecule, two OH and one HH distance constraints are treated as three pairwise interactions. In case of fix rigid, all constraint forces in the molecule are treated as a single many-body interaction with a single centroid position. In case of water molecule, the formula expression would become identical to that of the three-body angle interaction. Although the total system virial is the same as compute stress/atom, compute centroid/stress/atom is known to result in more consistent heat flux values for angle, dihedrals, improper and constraint force contributions when computed via compute heat/flux.

If no extra keywords are listed, the kinetic contribution all of the virial contribution terms are included in the per-atom stress tensor. If any extra keywords are listed, only those terms are summed to compute the tensor. The virial keyword means include all terms except the kinetic energy $ke$.

Note that the stress for each atom is due to its interaction with all other atoms in the simulation, not just with other atoms in the group.

Details of how compute stress/atom obtains the virial for individual atoms for either pairwise or many-body potentials, and including the effects of periodic boundary conditions is discussed in (Thompson). The basic idea for many-body potentials is to treat each component of the force computation between a small cluster of atoms in the same manner as in the formula above for bond, angle, dihedral, etc interactions. Namely the quantity $r \cdot F$ is summed over the atoms in the interaction, with the $r$ vectors unwrapped by periodic boundaries so that the cluster of atoms close together. The total contribution for the cluster interaction is divided evenly among those atoms.

Details of how compute centroid/stress/atom obtains the virial for individual atoms are given in (Surblys2019) and (Surblys2021), where the idea is that the virial of the atom $I$ is the result of only the force $F_I$ on the atom due to the interaction and its positional vector $r_{10}$, relative to the geometric center of the interacting atoms, regardless of the number of participating atoms. The periodic boundary treatment is identical to that of compute stress/atom, and both of them reduce to identical expressions for two-body interactions, i.e. computed values for contributions from bonds and two-body pair styles, such as Lennard-Jones, will be the same, while contributions from angles, dihedrals and impropers will be different.

The dihedral_style charmm style calculates pairwise interactions between 1-4 atoms. The virial contribution of these terms is included in the pair virial, not the dihedral virial.

The KSpace contribution is calculated using the method in (Heyes) for the Ewald method and by the methodology described in (Sirk) for PPPM. The choice of KSpace solver is specified by the kspace_style pppm command. Note that for PPPM, the calculation requires 6 extra FFTs each timestep that per-atom stress is calculated. Thus it can significantly increase the cost of the PPPM calculation if it is needed on a large fraction of the simulation timesteps.

The temp-ID argument can be used to affect the per-atom velocities used in the kinetic energy contribution to the total stress. If the kinetic energy is not included in the stress, than the temperature compute is not used and can be specified as NULL. If the kinetic energy is included and you wish to use atom velocities as-is, then temp-ID can also be specified as NULL. If desired, the specified temperature compute can be one that subtracts off a bias to leave each atom with only a thermal velocity to use in the formula above, e.g. by subtracting a background streaming velocity. See the doc pages for individual compute commands to determine which ones include a bias.

Note that as defined in the formula, per-atom stress is the negative of the per-atom pressure tensor. It is also really a stress*volume formulation, meaning the computed quantity is in units of pressure*volume. It would need to be divided by a per-atom volume to have units of stress (pressure), but an individual atom’s volume is not well defined or easy to compute in a deformed solid or a liquid. See the compute voronoi/atom command for one possible way to estimate a per-atom volume.
Thus, if the diagonal components of the per-atom stress tensor are summed for all atoms in the system and the sum is divided by $dV$, where $d$ = dimension and $V$ is the volume of the system, the result should be $-P$, where $P$ is the total pressure of the system.

These lines in an input script for a 3d system should yield that result. I.e. the last 2 columns of thermo output will be the same:

```plaintext
compute peratom all stress/atom NULL
thermo_style custom step temp etotal press v_press
```

**Note:** The per-atom stress does not include any Lennard-Jones tail corrections to the pressure added by the `pair_modify tail yes` command, since those are contributions to the global system pressure.

### 18.118.4 Output info

Compute `stress/atom` calculates a per-atom array with 6 columns, which can be accessed by indices 1-6 by any command that uses per-atom values from a compute as input. Compute `centroid/stress/atom` produces a per-atom array with 9 columns, but otherwise can be used in an identical manner to compute `stress/atom`. See the Howto output page for an overview of LAMMPS output options.

The ordering of the 6 columns for `stress/atom` is as follows: xx, yy, zz, xy, xz, yz. The ordering of the 9 columns for `centroid/stress/atom` is as follows: xx, yy, zz, xy, xz, yz, yx, zx, zy.

The per-atom array values will be in pressure*volume units as discussed above.

### 18.118.5 Restrictions

Currently, compute `centroid/stress/atom` does not support pair styles with many-body interactions (EAM is an exception, since its computations are performed pairwise), nor granular pair styles with pairwise forces which are not aligned with the vector between the pair of particles. All bond styles are supported. All angle, dihedral, improper styles are supported with the exception of INTEL and KOKKOS variants of specific styles. It also does not support models with long-range Coulombic or dispersion forces, i.e. the kspace_style command in LAMMPS. It also does not implement the following fixes which add rigid-body constraints: `fix rigid/*` and the OpenMP accelerated version of `fix rigid/small`, while all other `fix rigid/*/small` are implemented.

LAMMPS will generate an error if one of these options is included in your model. Extension of centroid stress calculations to these force and fix styles is planned for the future.

18.120.2 Description

Compute `stress/mop` and `stress/mop/profile` define computations that calculate components of the local stress tensor using the method of planes (Todd). Specifically in compute `stress/mop` calculates 3 components are computed in directions `dir,x`, `dir,y`, and `dir,z`; where `dir` is the direction normal to the plane, while in compute `stress/mop/profile` the profile of the stress is computed.

Contrary to methods based on histograms of atomic stress (i.e. using `compute stress/atom`), the method of planes is compatible with mechanical balance in heterogeneous systems and at interfaces (Todd).

The stress tensor is the sum of a kinetic term and a configurational term, which are given respectively by Eq. (21) and Eq. (16) in (Todd). For the kinetic part, the algorithm considers that atoms have crossed the plane if their positions at times `t-dt` and `t` are one on either side of the plane, and uses the velocity at time `t-dt/2` given by the velocity-Verlet algorithm.

Between one and three keywords can be used to indicate which contributions to the stress must be computed: kinetic stress (kin), configurational stress (conf), and/or total stress (total).

NOTE 1: The configurational stress is computed considering all pairs of atoms where at least one atom belongs to group group-ID.

NOTE 2: The local stress does not include any Lennard-Jones tail corrections to the stress added by the `pair_modify tail yes` command, since those are contributions to the global system pressure.

NOTE 3: The local stress profile generated by compute `stress/mop/profile` is similar to that obtained by compute `stress/cartesian`. A key difference is that compute `stress/mop/profile` considers particles crossing a set of planes, while compute `stress/cartesian` computes averages for a set of small volumes. More information on the similarities and differences can be found in (Ikeshoji).

18.120.3 Output info

Compute `stress/mop` calculates a global vector (indices starting at 1), with 3 values for each declared keyword (in the order the keywords have been declared). For each keyword, the stress tensor components are ordered as follows: `stress_dir,x`, `stress_dir,y`, and `stress_dir,z`.

Compute `stress/mop/profile` instead calculates a global array, with 1 column giving the position of the planes where the stress tensor was computed, and with 3 columns of values for each declared keyword (in the order the keywords have been declared). For each keyword, the profiles of stress tensor components are ordered as follows: `stress_dir,x`; `stress_dir,y`; and `stress_dir,z`.

The values are in pressure units.

The values produced by this compute can be accessed by various output commands. For instance, the results can be written to a file using the `fix ave/time` command. Please see the example in the examples/PACKAGES/mop folder.

18.120.4 Restrictions

These styles are part of the EXTRA-COMPUTE package. They are only enabled if LAMMPS is built with that package. See the Build package doc page on for more info.

The method is only implemented for 3d orthogonal simulation boxes whose size does not change in time, and axis-aligned planes.

The method only works with two-body pair interactions, because it requires the class method pair->single() to be implemented. In particular, it does not work with more than two-body pair interactions, intra-molecular interactions, and long range (kspace) interactions.

18.123.3 Description

Compute **stress/cartesian**, compute **stress/cylinder**, and compute **stress/spherical** define computations that calculate profiles of the diagonal components of the local stress tensor in the specified coordinate system. The stress tensor is split into a kinetic contribution $P^k$ and a virial contribution $P^v$. The sum gives the total stress tensor $P = P^k + P^v$. These computes can for example be used to calculate the diagonal components of the local stress tensor of interfaces with flat, cylindrical, or spherical symmetry. These computes obey momentum balance through fluid interfaces. They use the Irving-Kirkwood contour, which is the straight line between particle pairs.

The **stress/cartesian** computes the stress profile along one or two Cartesian coordinates, as described in *Ikeshoji*. The compute **stress/cylinder** computes the stress profile along the radial direction in cylindrical coordinates, as described in *Addington*. The compute **stress/spherical** computes the stress profile along the radial direction in spherical coordinates, as described in *Ikeshoji*.

18.123.4 Output info

The output columns for **stress/cartesian** are the position of the center of the local volume in the first and second dimensions, number density, $P^k_{xx}$, $P^k_{yy}$, $P^k_{zz}$, $P^v_{xx}$, $P^v_{yy}$, and $P^v_{zz}$. There are 8 columns when one dimension is specified and 9 columns when two dimensions are specified. The number of bins/rows are $(L1/bin\_width1)*(L2/bin\_width2)$, $L1$ and $L2$ are the sizes of the simulation box in the specified dimensions, and $bin\_width1$ and $bin\_width2$ are the specified bin widths. When only one dimension is specified the number of bins/rows are $L1/bin\_width$.

The default output columns for **stress/cylinder** are the radius to the center of the cylindrical shell, number density, $P^k_{rr}$, $P^k_{\phi\phi}$, $P^k_{zz}$, $P^v_{rr}$, $P^v_{\phi\phi}$, and $P^v_{zz}$. When the keyword $ke$ is set to no, the kinetic contributions are not calculated, and consequently there are only 5 columns the radius to the center of the cylindrical shell, number density, $P^v_{rr}$, $P^v_{\phi\phi}$, $P^v_{zz}$. The number of bins/rows are $Rmax/bin\_width$.

The output columns for **stress/spherical** are the radius to the center of the spherical shell, number density, $P^k_{rr}$, $P^k_{\theta\theta}$, $P^k_{\phi\phi}$, $P^v_{rr}$, $P^v_{\theta\theta}$, and $P^v_{\phi\phi}$. There are 8 columns and the number of bins/rows are $Rmax/bin\_width$.

This array can be output with `fix ave/time`,

```bash
compute p all stress/cartesian x 0.1
fix 2 all ave/time 100 1 100 c_p[*] file dump_p.out mode vector
```

The values calculated by this compute are “intensive”. The stress values will be in pressure units. The number density values are in inverse volume units.

NOTE 1: The local stress does not include any Lennard-Jones tail corrections to the stress added by the `pair_modify tail yes` command, since those are contributions to the global system pressure.

NOTE 2: The local stress profiles generated by these computes are similar to those obtained by the `method-of-planes (MOP)` command. A key difference is that compute `stress/mop/profile <compute_stress_mop>` considers particles crossing a set of planes, while `stress/cartesian` computes averages for a set of small volumes. More information on the similarities and differences can be found in *Ikeshoji*. 

18.123. compute stress/spherical command 1833
18.123.5 Restrictions

These computes calculate the stress tensor contributions for pair styles only (i.e. no bond, angle, dihedral, etc. contributions, and in the presence of bonded interactions, the result will be incorrect due to exclusions for special bonds) and requires pairwise force calculations not available for most many-body pair styles. K-space calculations are also excluded.

These computes are part of the EXTRA-COMPUTE package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

18.129.2 Examples

compute 1 lower force/tally upper
compute 1 left pe/tally right
compute 1 lower stress/tally lower
compute 1 subregion heat/flux/tally all
compute 1 liquid heat/flux/virial/tally solid

18.129.3 Description

Define a computation that calculates properties between two groups of atoms by accumulating them from pairwise non-bonded computations. Except for heat/flux/virial/tally, the two groups can be the same. This is similar to compute group/group only that the data is accumulated directly during the non-bonded force computation. The computes force/tally, pe/tally, stress/tally, and heat/flux/tally are primarily provided as example how to program additional, more sophisticated computes using the tally callback mechanism. Compute pe/mol/tally is one such style, that can - through using this mechanism - separately tally intermolecular and intramolecular energies. Something that would otherwise be impossible without integrating this as a core functionality into the base classes of LAMMPS.

Compute heat/flux/tally obtains the heat flux (strictly speaking, heat flow) inside the first group, which is the sum of the convective contribution due to atoms in the first group and the virial contribution due to interaction between the first and second groups:

\[
Q = \sum_{i \in \text{group 1}} e_i v_i + \frac{1}{2} \sum_{i \in \text{group 1}} \sum_{j \in \text{group 2}, j \neq i} (F_{ij} \cdot v_j) \mathbf{r}_{ij}
\]

When the second group in heat/flux/tally is set to “all”, the resulting values will be identical to that obtained by compute heat/flux, provided only pairwise interactions exist.

Compute heat/flux/virial/tally obtains the total virial heat flux (strictly speaking, heat flow) into the first group due to interaction with the second group, and is defined as:

\[
Q = \frac{1}{2} \sum_{i \in \text{group 1}} \sum_{j \in \text{group 2}} F_{ij} \cdot (v_i + v_j)
\]

Although, the heat/flux/virial/tally compute does not include the convective term, it can be used to obtain the total heat flux over control surfaces, when there are no particles crossing over, such as is often in solid-solid and solid-liquid interfaces. This would be identical to the method of planes method. Note that the heat/flux/virial/tally compute is distinctly different from the heat/flux and heat/flux/tally computes, that are essentially volume averaging methods. The following example demonstrates the difference:

# System with only pairwise interactions.
# Non-periodic boundaries in the x direction.
# Has LeftLiquid and RightWall groups along x direction.

# Heat flux over the solid-liquid interface
compute hflow_hfvt RightWall heat/flux/virial/tally LeftLiquid
variable hflux_hfvt equal c_hflow_hfvt/(ly^4/lz)

# x component of approximate heat flux vector inside the liquid region,
# two approaches.
# (continues on next page)
compute myKE all ke/atom
compute myPE all pe/atom
compute myStress all stress/atom NULL virial
compute hflow_hf LeftLiquid heat/flux myKE myPE myStress
variable hflux_hf equal c_hflow_hf[1]/${volLiq}
#
compute hflow_hft LeftLiquid heat/flux/tally all
variable hflux_hft equal c_hflow_hft[1]/${volLiq}
# Pressure over the solid-liquid interface, three approaches.
#
compute force_gg RightWall group/group LeftLiquid
variable press_gg equal c_force_gg[1]/(ly*lz)
#
compute force_ft RightWall force/tally LeftLiquid
compute rforce_ft RightWall reduce sum c_force_ft[1]
variable press_ft equal c_rforce_ft/(ly*lz)
#
compute rforce_hfvt all reduce sum c_hflow_hfvt[1]
variable press_hfvt equal c_rforce_hfvt/(ly*lz)

The pairwise contributions are computing via a callback that the compute registers with the non-bonded pairwise force computation. This limits the use to systems that have no bonds, no Kspace, and no many-body interactions. On the other hand, the computation does not have to compute forces or energies a second time and thus can be much more efficient. The callback mechanism allows to write more complex pairwise property computations.

18.129.4 Output info

- Compute pe/tally calculates a global scalar (the energy) and a per atom scalar (the contributions of the single atom to the global scalar).

- Compute pe/mol/tally calculates a global 4-element vector containing (in this order): evdwl and ecoul for intramolecular pairs and evdwl and ecoul for intermolecular pairs. Since molecules are identified by their molecule IDs, the partitioning does not have to be related to molecules, but the energies are tallied into the respective slots depending on whether the molecule IDs of a pair are the same or different.

- Compute force/tally calculates a global scalar (the force magnitude) and a per atom 3-element vector (force contribution from each atom).

- Compute stress/tally calculates a global scalar (average of the diagonal elements of the stress tensor) and a per atom vector (the 6 elements of stress tensor contributions from the individual atom).

- As in compute heat/flux, compute heat/flux/tally calculates a global vector of length 6, where the first 3 components are the x, y, z components of the full heat flow vector, and the next 3 components are the corresponding components of just the convective portion of the flow, i.e. the first term in the equation for Q.

- Compute heat/flux/virial/tally calculates a global scalar (heat flow) and a per atom 3-element vector (contribution to the force acting over atoms in the first group from individual atoms in both groups).

Both the scalar and vector values calculated by this compute are “extensive”.
18.129.5 Restrictions

This compute is part of the TALLY package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

Not all pair styles can be evaluated in a pairwise mode as required by this compute. For example, 3-body and other many-body potentials, such as Tersoff and Stillinger-Weber cannot be used. EAM potentials only include the pair potential portion of the EAM interaction when used by this compute, not the embedding term. Also bonded or Kspace interactions do not contribute to this compute.

When used with dynamic groups, a run 0 command needs to be inserted in order to initialize the dynamic groups before accessing the computes.

- index = index of chemical species (1 to Nspecies)

18.130.2 Examples

```
compute 1 all tdpd/cc/atom 2
```

18.130.3 Description

Define a computation that calculates the per-atom chemical concentration of a specified species for each tDPD particle in a group.

The chemical concentration of each species is defined as the number of molecules carried by a tDPD particle for dilute solution. For more details see (Li2015).
18.130.4 Output info

This compute calculates a per-atom vector, which can be accessed by any command that uses per-atom values from a compute as input. See the Howto output page for an overview of LAMMPS output options. The per-atom vector values will be in the units of chemical species per unit mass.

18.130.5 Restrictions

This compute is part of the DPD-MESO package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

18.130.6 Related commands

pair_style tdpd

18.130.7 Default

none

18.131 compute temp command

Accelerator Variants: temp/kk

18.131.1 Syntax

```
compute ID group-ID temp
```

- ID, group-ID are documented in compute command
- temp = style name of this compute command

18.131.2 Examples

```
compute 1 all temp
compute myTemp mobile temp
```
18.131.3 Description

Define a computation that calculates the temperature of a group of atoms. A compute of this style can be used by any command that computes a temperature, e.g. `thermo_modify`, `fix temp/rescale`, `fix npt`, etc.

The temperature is calculated by the formula $KE = \frac{dim}{2} N k T$, where $KE = \text{total kinetic energy of the group of atoms}$ (sum of $1/2 m v^2$), $dim = 2$ or $3 = \text{dimensionality of the simulation}$, $N = \text{number of atoms in the group}$, $k = \text{Boltzmann constant}$, and $T = \text{temperature}$.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that $v^2$ is replaced by $vx*vy$ for the xy component, etc. The 6 components of the vector are ordered $xx, yy, zz, xy, xz, yz$.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the `dynamic` option of the `compute_modify` command if this is not the case.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as `fix shake` and `fix rigid`. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the `extra` option of the `compute_modify` command.

A compute of this style with the ID of “thermo_temp” is created when LAMMPS starts up, as if this command were in the input script:

```
compute thermo_temp all temp
```

See the “thermo_style” command for more details.

See the Howto thermostat page for a discussion of different ways to compute temperature and perform thermostating.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

18.131.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature units. The vector values will be in energy units.
18.131.5 Restrictions

none

18.132 compute temp/asphere command

18.132.1 Syntax

compute ID group-ID temp/asphere keyword value ...

• ID, group-ID are documented in compute command
• temp/asphere = style name of this compute command
• zero or more keyword/value pairs may be appended
• keyword = bias or dof
  bias value = bias-ID
  bias-ID = ID of a temperature compute that removes a velocity bias
  dof value = all or rotate
  all = compute temperature of translational and rotational degrees of freedom
  rotate = compute temperature of just rotational degrees of freedom

18.132.2 Examples

compute 1 all temp/asphere
compute myTemp mobile temp/asphere bias tempCOM
compute myTemp mobile temp/asphere dof rotate

18.132.3 Description

Define a computation that calculates the temperature of a group of aspherical particles, including a contribution from both their translational and rotational kinetic energy. This differs from the usual compute temp command, which assumes point particles with only translational kinetic energy.

Only finite-size particles (aspherical or spherical) can be included in the group. For 3d finite-size particles, each has 6 degrees of freedom (3 translational, 3 rotational). For 2d finite-size particles, each has 3 degrees of freedom (2 translational, 1 rotational).

Note: This choice for degrees of freedom (dof) assumes that all finite-size aspherical or spherical particles in your model will freely rotate, sampling all their rotational dof. It is possible to use a combination of interaction potentials
and fixes that induce no torque or otherwise constrain some of all of your particles so that this is not the case. Then there are less dof and you should use the `compute_modify extra` command to adjust the dof accordingly.

For example, an aspherical particle with all three of its shape parameters the same is a sphere. If it does not rotate, then it should have 3 dof instead of 6 in 3d (or 2 instead of 3 in 2d). A uniaxial aspherical particle has two of its three shape parameters the same. If it does not rotate around the axis perpendicular to its circular cross section, then it should have 5 dof instead of 6 in 3d. The latter is the case for uniaxial ellipsoids in a GayBerne model since there is no induced torque around the optical axis. It will also be the case for bi-axial ellipsoids when exactly two of the semiaxes have the same length and the corresponding relative well depths are equal.

The translational kinetic energy is computed the same as is described by the `compute temp` command. The rotational kinetic energy is computed as \( \frac{1}{2} I w^2 \), where \( I \) is the inertia tensor for the aspherical particle and \( w \) is its angular velocity, which is computed from its angular momentum.

**Note:** For 2d models, particles are treated as ellipsoids, not ellipses, meaning their moments of inertia will be the same as in 3d.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute. The formula for the components of the tensor is the same as the above formula, except that \( v^2 \) and \( w^2 \) are replaced by \( v_x v_y \) and \( w_x w_y \) for the xy component, and the appropriate elements of the inertia tensor are used. The 6 components of the vector are ordered \( xx, yy, zz, xy, xz, yz \).

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the `dynamic` option of the `compute_modify` command if this is not the case.

This compute subtracts out translational degrees-of-freedom due to fixes that constrain molecular motion, such as `fix shake` and `fix rigid`. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the `extra` option of the `compute_modify` command.

See the *Howto thermostat* page for a discussion of different ways to compute temperature and perform thermostatting.

The keyword/value option pairs are used in the following ways.

For the `bias` keyword, `bias-ID` refers to the ID of a temperature compute that removes a “bias” velocity from each atom. This allows `compute temp/sphere` to compute its thermal temperature after the translational kinetic energy components have been altered in a prescribed way, e.g. to remove a flow velocity profile. Thermostats that use this compute will work with this bias term. See the doc pages for individual computes that calculate a temperature and the doc pages for fixes that perform thermostatting for more details.

For the `dof` keyword, a setting of *all* calculates a temperature that includes both translational and rotational degrees of freedom. A setting of *rotate* calculates a temperature that includes only rotational degrees of freedom.
18.132.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature units. The vector values will be in energy units.

18.132.5 Restrictions

This compute is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This compute requires that atoms store angular momentum and a quaternion as defined by the atom_style ellipsoid command.

All particles in the group must be finite-size. They cannot be point particles, but they can be aspherical or spherical as defined by their shape attribute.

18.132.6 Related commands

18.133.2 Examples

```
compute 1 all temp/body
compute myTemp mobile temp/body bias tempCOM
compute myTemp mobile temp/body dof rotate
```

18.133.3 Description

Define a computation that calculates the temperature of a group of body particles, including a contribution from both their translational and rotational kinetic energy. This differs from the usual `compute temp` command, which assumes point particles with only translational kinetic energy.

Only body particles can be included in the group. For 3d particles, each has 6 degrees of freedom (3 translational, 3 rotational). For 2d body particles, each has 3 degrees of freedom (2 translational, 1 rotational).

**Note:** This choice for degrees of freedom (dof) assumes that all body particles in your model will freely rotate, sampling all their rotational dof. It is possible to use a combination of interaction potentials and fixes that induce no torque or otherwise constrain some of all of your particles so that this is not the case. Then there are less dof and you should use the `compute_modify extra` command to adjust the dof accordingly.

The translational kinetic energy is computed the same as is described by the `compute temp` command. The rotational kinetic energy is computed as \( \frac{1}{2} I \omega^2 \), where \( I \) is the inertia tensor for the aspherical particle and \( \omega \) is its angular velocity, which is computed from its angular momentum.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute. The formula for the components of the tensor is the same as the above formula, except that \( v^2 \) and \( w^2 \) are replaced by \( vx*vy \) and \( wx*wy \) for the xy component, and the appropriate elements of the inertia tensor are used. The 6 components of the vector are ordered \( xx, yy, zz, xy, xz, yz \).

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the `dynamic` option of the `compute_modify` command if this is not the case.

This compute subtracts out translational degrees-of-freedom due to fixes that constrain molecular motion, such as `fix shake` and `fix rigid`. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the `extra` option of the `compute_modify` command.

See the Howto thermostat page for a discussion of different ways to compute temperature and perform thermostating.

The keyword/value option pairs are used in the following ways.

For the `bias` keyword, `bias-ID` refers to the ID of a temperature compute that removes a “bias” velocity from each atom. This allows compute temp/sphere to compute its thermal temperature after the translational kinetic energy components have been altered in a prescribed way, e.g. to remove a flow velocity profile. Thermostats that use this compute will work with this bias term. See the doc pages for individual computes that calculate a temperature and the doc pages for fixes that perform thermostating for more details.

For the `dof` keyword, a setting of `all` calculates a temperature that includes both translational and rotational degrees of freedom. A setting of `rotate` calculates a temperature that includes only rotational degrees of freedom.
18.133.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature units. The vector values will be in energy units.

18.133.5 Restrictions

This compute is part of the BODY package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This compute requires that atoms store angular momentum and a quaternion as defined by the atom_style body command.

```

18.134.3 Description

Define a computation that calculates the temperature of a group of atoms that are also in chunks, after optionally subtracting out the center-of-mass velocity of each chunk. By specifying optional values, it can also calculate the per-chunk temperature or energies of the multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a compute chunk/atom command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the compute chunk/atom and Howto chunk doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

The temperature is calculated by the formula KE = DOF/2 k T, where KE = total kinetic energy of all atoms assigned to chunks (sum of 1/2 m v^2), DOF = the total number of degrees of freedom for those atoms, k = Boltzmann constant, and T = temperature.

The DOF is calculated as N*adof + Nchunk*cdof, where N = number of atoms contributing to the KE, adof = degrees of freedom per atom, and cdof = degrees of freedom per chunk. By default adof = 2 or 3 = dimensionality of system, as set via the dimension command, and cdof = 0.0. This gives the usual formula for temperature.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that v^2 is replaced by vx*vy for the xy component, etc. The 6 components of the vector are ordered xx, yy, zz, xy, xz, yz.

Note that the number of atoms contributing to the temperature is calculated each time the temperature is evaluated since it is assumed the atoms may be dynamically assigned to chunks. Thus there is no need to use the dynamic option of the compute_modify command for this compute style.

If any optional values are specified, then per-chunk quantities are also calculated and stored in a global array, as described below.

The temp value calculates the temperature for each chunk by the formula KE = DOF/2 k T, where KE = total kinetic energy of the chunk of atoms (sum of 1/2 m v^2), DOF = the total number of degrees of freedom for all atoms in the chunk, k = Boltzmann constant, and T = temperature.

The DOF in this case is calculated as N*adof + cdof, where N = number of atoms in the chunk, adof = degrees of freedom per atom, and cdof = degrees of freedom per chunk. By default adof = 2 or 3 = dimensionality of system, as set via the dimension command, and cdof = 0.0. This gives the usual formula for temperature.

The kecom value calculates the kinetic energy of each chunk as if all its atoms were moving with the velocity of the center-of-mass of the chunk.

The internal value calculates the internal kinetic energy of each chunk. The internal KE is summed over the atoms in the chunk using an internal “thermal” velocity for each atom, which is its velocity minus the center-of-mass velocity of the chunk.
Note that currently the global and per-chunk temperatures calculated by this compute only include translational degrees of freedom for each atom. No rotational degrees of freedom are included for finite-size particles. Also no degrees of freedom are subtracted for any velocity bias or constraints that are applied, such as `compute temp/partial`, or `fix shake` or `fix rigid`. This is because those degrees of freedom (e.g. a constrained bond) could apply to sets of atoms that are both included and excluded from a specific chunk, and hence the concept is somewhat ill-defined. In some cases, you can use the `adof` and `cdof` keywords to adjust the calculated degrees of freedom appropriately, as explained below.

Note that the per-chunk temperature calculated by this compute and the `fix ave/chunk temp` command can be different. This compute calculates the temperature for each chunk for a single snapshot. Fix ave/chunk can do that but can also time average those values over many snapshots, or it can compute a temperature as if the atoms in the chunk on different timesteps were collected together as one set of atoms to calculate their temperature. This compute allows the center-of-mass velocity of each chunk to be subtracted before calculating the temperature; fix ave/chunk does not.

**Note:** Only atoms in the specified group contribute to the calculations performed by this compute. The `compute chunk/atom` command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

The simplest way to output the per-chunk results of the compute temp/chunk calculation to a file is to use the `fix ave/time` command, for example:

```
compute ccl all chunk/atom molecule
compute myChunk all temp/chunk ccl temp
fix 1 all ave/time 100 1 100 c_myChunk[1] file tmp.out mode vector
```

The keyword/value option pairs are used in the following ways.

The `com` keyword can be used with a value of `yes` to subtract the velocity of the center-of-mass for each chunk from the velocity of the atoms in that chunk, before calculating either the global or per-chunk temperature. This can be useful if the atoms are streaming or otherwise moving collectively, and you wish to calculate only the thermal temperature.

For the `bias` keyword, `bias-ID` refers to the ID of a temperature compute that removes a “bias” velocity from each atom. This also allows calculation of the global or per-chunk temperature using only the thermal temperature of atoms in each chunk after the translational kinetic energy components have been altered in a prescribed way, e.g. to remove a velocity profile. It also applies to the calculation of the other per-chunk values, such as `kecom` or `internal`, which involve the center-of-mass velocity of each chunk, which is calculated after the velocity bias is removed from each atom. Note that the temperature compute will apply its bias globally to the entire system, not on a per-chunk basis.

The `adof` and `cdof` keywords define the values used in the degree of freedom (DOF) formulas used for the global or per-chunk temperature, as described above. They can be used to calculate a more appropriate temperature for some kinds of chunks. Here are 3 examples:

If spatially binned chunks contain some number of water molecules and `fix shake` is used to make each molecule rigid, then you could calculate a temperature with 6 degrees of freedom (DOF) (3 translational, 3 rotational) per molecule by setting `adof` to 2.0.

If `compute temp/partial` is used with the `bias` keyword to only allow the x component of velocity to contribute to the temperature, then `adof = 1.0` would be appropriate.

If each chunk consists of a large molecule, with some number of its bonds constrained by `fix shake` or the entire molecule by `fix rigid/small`, `adof = 0.0` and `cdof` could be set to the remaining degrees of freedom for the entire molecule (entire chunk in this case), e.g. 6 for 3d, or 3 for 2d, for a rigid molecule.
18.134.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

This compute also optionally calculates a global array, if one or more of the optional values are specified. The number of rows in the array = the number of chunks \( N_{chunk} \) as calculated by the specified compute chunk/atom command. The number of columns is the number of specified values (1 or more). These values can be accessed by any command that uses global array values from a compute as input. Again, see the Howto output doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”. The array values are “intensive”.

The scalar value will be in temperature units. The vector values will be in energy units. The array values will be in temperature units for the temp value, and in energy units for the kecom and internal values.

18.134.5 Restrictions

The com and bias keywords cannot be used together.

18.135 compute temp/com command

18.135.1 Syntax

```
compute ID group-ID temp/com
```

- ID, group-ID are documented in compute command
- temp/com = style name of this compute command

18.135.2 Examples

```
compute 1 all temp/com
compute myTemp mobile temp/com
```
18.135.3 Description

Define a computation that calculates the temperature of a group of atoms, after subtracting out the center-of-mass velocity of the group. This is useful if the group is expected to have a non-zero net velocity for some reason. A compute of this style can be used by any command that computes a temperature, e.g. `thermo_modify`, `fix temp/rescale`, `fix npt`, etc.

After the center-of-mass velocity has been subtracted from each atom, the temperature is calculated by the formula $KE = \frac{\text{dim}}{2} N k T$, where $KE = \text{total kinetic energy of the group of atoms (sum of } \frac{1}{2} m v^2 \text{)}, \text{dim} = 2 \text{ or } 3 = \text{dimensionality of the simulation}, N = \text{number of atoms in the group}, k = \text{Boltzmann constant}, \text{and } T = \text{temperature}.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that $v^2$ is replaced by $v_x v_y$ for the $xy$ component, etc. The 6 components of the vector are ordered $xx$, $yy$, $zz$, $xy$, $xz$, $yz$.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the `dynamic` option of the `compute_modify` command if this is not the case.

The removal of the center-of-mass velocity by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostatting then this bias will be subtracted from each atom, thermostatting of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostatting fixes that work in this way include `fix nvt`, `fix temp/rescale`, `fix temp/berendsen`, and `fix langevin`.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as `fix shake` and `fix rigid`. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the `extra` option of the `compute_modify` command.

See the `Howto thermostat` page for a discussion of different ways to compute temperature and perform thermostatting.

18.135.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the `Howto output` page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature `units`. The vector values will be in energy `units`.

18.136.2 Examples

```
compute oxygen_c-s all temp/cs O_core O_shell
compute core_shells all temp/cs cores shells
```

18.136.3 Description

Define a computation that calculates the temperature of a system based on the center-of-mass velocity of atom pairs that are bonded to each other. This compute is designed to be used with the adiabatic core/shell model of (Mitchell and Finchham). See the Howto coreshell page for an overview of the model as implemented in LAMMPS. Specifically, this compute enables correct temperature calculation and thermostating of core/shell pairs where it is desirable for the internal degrees of freedom of the core/shell pairs to not be influenced by a thermostat. A compute of this style can be used by any command that computes a temperature via fix_modify e.g. fix temp/rescale, fix npt, etc.

Note that this compute does not require all ions to be polarized, hence defined as core/shell pairs. One can mix core/shell pairs and ions without a satellite particle if desired. The compute will consider the non-polarized ions according to the physical system.

For this compute, core and shell particles are specified by two respective group IDs, which can be defined using the group command. The number of atoms in the two groups must be the same and there should be one bond defined between a pair of atoms in the two groups. Non-polarized ions which might also be included in the treated system should not be included into either of these groups, they are taken into account by the group-ID (second argument) of the compute.

The temperature is calculated by the formula \( KE = \frac{\text{dim}}{2} N k T \), where \( KE \) = total kinetic energy of the group of atoms (sum of \( \frac{1}{2} m v^2 \)), \( \text{dim} = 2 \) or \( 3 \) = dimensionality of the simulation, \( N \) = number of atoms in the group, \( k \) = Boltzmann constant, and \( T \) = temperature. Note that the velocity of each core or shell atom used in the KE calculation is the velocity of the center-of-mass (COM) of the core/shell pair the atom is part of.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that \( v^2 \) is replaced by \( vx*vy \) for the xy component, etc. The 6 components of the vector are ordered xx, yy, zz, xy, xz, yz. In contrast to the temperature, the velocity of each core or shell atom is taken individually.
The change this fix makes to core/shell atom velocities is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. This “bias” is the velocity of the atom relative to the COM velocity of the core/shell pair. If this compute is used with a fix command that performs thermostating then this bias will be subtracted from each atom, thermostating of the remaining COM velocity will be performed, and the bias will be added back in. This means the thermostating will effectively be performed on the core/shell pairs, instead of on the individual core and shell atoms. Thermostatting fixes that work in this way include \texttt{fix nvt}, \texttt{fix temp/rescale}, \texttt{fix temp/berendsen}, and \texttt{fix langevin}.

The internal energy of core/shell pairs can be calculated by the \texttt{compute temp/chunk} command, if chunks are defined as core/shell pairs. See the \textit{Howto coreshell} page doc page for more discussion on how to do this.

\textbf{18.136.4 Output info}

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature \textit{units}. The vector values will be in energy \textit{units}.

\textbf{18.136.5 Restrictions}

- temp/deform = style name of this compute command

18.137.2 Examples

```
compute myTemp all temp/deform
```

18.137.3 Description

Define a computation that calculates the temperature of a group of atoms, after subtracting out a streaming velocity induced by the simulation box changing size and/or shape, for example in a non-equilibrium MD (NEMD) simulation. The size/shape change is induced by use of the `fix deform` command. A compute of this style is created by the `fix nvt/sllod` command to compute the thermal temperature of atoms for thermostating purposes. A compute of this style can also be used by any command that computes a temperature, e.g. `thermo_modify`, `fix temp/rescale`, `fix npt`, etc.

The deformation fix changes the box size and/or shape over time, so each atom in the simulation box can be thought of as having a “streaming” velocity. For example, if the box is being sheared in x, relative to y, then atoms at the bottom of the box (low y) have a small x velocity, while atoms at the top of the box (hi y) have a large x velocity. This position-dependent streaming velocity is subtracted from each atom’s actual velocity to yield a thermal velocity which is used to compute the temperature.

**Note:** `fix deform` has an option for remapping either atom coordinates or velocities to the changing simulation box. When using this compute in conjunction with a deforming box, `fix deform` should NOT remap atom positions, but rather should let atoms respond to the changing box by adjusting their own velocities (or let `fix deform` remap the atom velocities, see it’s remap option). If `fix deform` does remap atom positions, then they appear to move with the box but their velocity is not changed, and thus they do NOT have the streaming velocity assumed by this compute. LAMMPS will warn you if `fix deform` is defined and its remap setting is not consistent with this compute.

After the streaming velocity has been subtracted from each atom, the temperature is calculated by the formula \( KE = \frac{1}{2}N k T \), where \( KE \) = total kinetic energy of the group of atoms (sum of \( 1/2 m v^2 \)), \( dim = 2 \) or \( 3 \) = dimensionality of the simulation, \( N \) = number of atoms in the group, \( k \) = Boltzmann constant, and \( T \) = temperature. Note that \( v \) in the kinetic energy formula is the atom’s thermal velocity.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that \( v^2 \) is replaced by \( v_x v_y \) for the \( xy \) component, etc. The 6 components of the vector are ordered \( xx, yy, zz, xy, xz, yz \).

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the `dynamic` option of the `compute_modify` command if this is not the case.

The removal of the box deformation velocity component by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostating then this bias will be subtracted from each atom, thermostating of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostatting fixes that work in this way include `fix nvt`, `fix temp/rescale`, `fix temp/berendsen`, and `fix langevin`.

18.137. compute temp/deform command
Note: The temperature calculated by this compute is only accurate if the atoms are indeed moving with a stream velocity profile that matches the box deformation. If not, the compute will subtract off an incorrect stream velocity, yielding a bogus thermal temperature. You should NOT assume that your atoms are streaming at the same rate the box is deforming. Rather, you should monitor their velocity profile, e.g. via the fix ave/chunk command. And you can compare the results of this compute to compute temp/profile, which actually calculates the stream profile before subtracting it. If the two computes do not give roughly the same temperature, then your atoms are not streaming consistent with the box deformation. See the fix deform command for more details on ways to get atoms to stream consistently with the box deformation.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as fix shake and fix rigid. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the extra option of the compute_modify command.

See the Howto thermostat page for a discussion of different ways to compute temperature and perform thermostatting.

18.137.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature units. The vector values will be in energy units.

compute TDRUDE all temp/drude
```

Example input scripts available: examples/PACKAGES/drude

18.139.3 Description

Define a computation that calculates the temperatures of core-Drude pairs. This compute is designed to be used with the `thermalized Drude oscillator model`. Polarizable models in LAMMPS are described on the `How to polarizable` doc page.

Drude oscillators consist of a core particle and a Drude particle connected by a harmonic bond, and the relative motion of these Drude oscillators is usually maintained cold by a specific thermostat that acts on the relative motion of the core-Drude particle pairs. Therefore, because LAMMPS considers Drude particles as normal atoms in its default temperature `compute` (`compute temp` command), the reduced temperature of the core-Drude particle pairs is not calculated correctly.

By contrast, this compute calculates the temperature of the cores using center-of-mass velocities of the core-Drude pairs, and the reduced temperature of the Drude particles using the relative velocities of the Drude particles with respect to their cores. Non-polarizable atoms are considered as cores. Their velocities contribute to the temperature of the cores.

18.139.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6, which can be accessed by indices 1-6, whose components are

1. temperature of the centers of mass (temperature units)
2. temperature of the dipoles (temperature units)
3. number of degrees of freedom of the centers of mass
4. number of degrees of freedom of the dipoles
5. kinetic energy of the centers of mass (energy units)
6. kinetic energy of the dipoles (energy units)

These values can be used by any command that uses global scalar or vector values from a compute as input. See the `How to output` page for an overview of LAMMPS output options.

Both the scalar value and the first two values of the vector calculated by this compute are “intensive”. The other 4 vector values are “extensive”.

18.140.1 Syntax

compute ID group-ID temp/eff

• ID, group-ID are documented in compute command
• temp/eff = style name of this compute command

18.140.2 Examples

compute 1 all temp/eff
compute myTemp mobile temp/eff

18.140.3 Description

Define a computation that calculates the temperature of a group of nuclei and electrons in the electron force field model. A compute of this style can be used by commands that compute a temperature, e.g. thermo_modify, fix npt/eff, etc.

The temperature is calculated by the formula \( KE = \frac{dim}{2} N k T \), where \( KE \) = total kinetic energy of the group of atoms (sum of \( \frac{1}{2} m v^2 \) for nuclei and sum of \( \frac{1}{2} (m v^2 + \frac{3}{4} m s^2) \) for electrons, where \( s \) includes the radial electron velocity contributions), \( dim = 2 \) or \( 3 \) = dimensionality of the simulation, \( N \) = number of atoms (only total number of nuclei in the eFF (see the pair_eff command) in the group, \( k \) = Boltzmann constant, and \( T \) = temperature. This expression is summed over all nuclear and electronic degrees of freedom, essentially by setting the kinetic contribution to the heat capacity to \( 3/2k \) (where only nuclei contribute). This subtlety is valid for temperatures well below the Fermi temperature, which for densities two to five times the density of liquid H2 ranges from 86,000 to 170,000 K.

Note: For eFF models, in order to override the default temperature reported by LAMMPS in the thermodynamic quantities reported via the thermo command, the user should apply a thermo_modify command, as shown in the following example:
A 6-component kinetic energy tensor is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that \( v^2 \) is replaced by \( vx \times vy \) for the xy component, etc. For the eFF, again, the radial electronic velocities are also considered.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the `dynamic` option of the `compute_modify` command if this is not the case.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as `fix shake` and `fix rigid`. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the `extra` option of the `compute_modify` command.

See the `Howto thermostat` page for a discussion of different ways to compute temperature and perform thermostatting.

### 18.140.4 Output info

The scalar value calculated by this compute is “intensive”, meaning it is independent of the number of atoms in the simulation. The vector values are “extensive”, meaning they scale with the number of atoms in the simulation.

### 18.140.5 Restrictions

This compute is part of the EFF package. It is only enabled if LAMMPS was built with that package. See the `Build package` page for more info.

### 18.140.6 Related commands

`compute temp/partial`, `compute temp/region`, `compute pressure`

### 18.140.7 Default

none

### 18.141 compute temp/partial command

#### 18.141.1 Syntax

```
compute ID group-ID temp/partial xflag yflag zflag
```

- ID, group-ID are documented in `compute` command
- `temp/partial` = style name of this compute command
- `xflag,yflag,zflag` = 0/1 for whether to exclude/include this dimension
18.141.2 Examples

```
compute newT flow temp/partial 1 1 0
```

18.141.3 Description

Define a computation that calculates the temperature of a group of atoms, after excluding one or more velocity components. A compute of this style can be used by any command that computes a temperature, e.g. `thermo_modify`, `fix temp/rescale`, `fix npt`, etc.

The temperature is calculated by the formula $KE = \frac{1}{2} N k T$, where $KE$ = total kinetic energy of the group of atoms (sum of $1/2 m v^2$), $dim$ = dimensionality of the simulation, $N$ = number of atoms in the group, $k$ = Boltzmann constant, and $T$ = temperature. The calculation of $KE$ excludes the $x$, $y$, or $z$ dimensions if $xflag$, $yflag$, or $zflag = 0$. The $dim$ parameter is adjusted to give the correct number of degrees of freedom.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the calculation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that $v^2$ is replaced by $vx*vy$ for the xy component, etc. The 6 components of the vector are ordered $xx$, $yy$, $zz$, $xy$, $xz$, $yz$.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the `dynamic` option of the `compute_modify` command if this is not the case.

The removal of velocity components by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostatting then this bias will be subtracted from each atom, thermostatting of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostatting fixes that work in this way include `fix nvt`, `fix temp/rescale`, `fix temp/berendsen`, and `fix langevin`.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as `fix shake` and `fix rigid`. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the `extra` option of the `compute_modify` command.

See the `Howto thermostat` page for a discussion of different ways to compute temperature and perform thermostatting.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Accelerator packages` page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Accelerator packages` page for more instructions on how to use the accelerated styles effectively.
18.141.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature units. The vector values will be in energy units.

18.142 compute temp/profile command

18.142.1 Syntax

```
compute ID group-ID temp/profile xflag yflag zflag binstyle args
```

- ID, group-ID are documented in compute command
- temp/profile = style name of this compute command
- xflag, yflag, zflag = 0/1 for whether to exclude/include this dimension
- binstyle = x or y or z or xy or yz or xz or xyz
  - x arg = Nx
  - y arg = Ny
  - z arg = Nz
  - xy args = Nx Ny
  - yz args = Ny Nz
  - xz args = Nx Nz
  - xyz args = Nx Ny Nz
  - Nx, Ny, Nz = number of velocity bins in x,y,z dimensions
- zero or more keyword/value pairs may be appended
- keyword = out
  - out value = tensor or bin
18.142.2 Examples

```plaintext
compute myTemp flow temp/profile 1 1 1 x 10  
compute myTemp flow temp/profile 1 1 1 x 10 out bin  
compute myTemp flow temp/profile 0 1 1 xyz 20 20 20
```

18.142.3 Description

Define a computation that calculates the temperature of a group of atoms, after subtracting out a spatially-averaged center-of-mass velocity field, before computing the kinetic energy. This can be useful for thermostating a collection of atoms undergoing a complex flow, e.g. via a profile-unbiased thermostat (PUT) as described in (Evans). A compute of this style can be used by any command that computes a temperature, e.g. `thermo_modify`, `fix temp/rescale`, `fix npt`, etc.

The `xflag`, `yflag`, `zflag` settings determine which components of average velocity are subtracted out.

The `binstyle` setting and its `Nx`, `Ny`, `Nz` arguments determine how bins are setup to perform spatial averaging. “Bins” can be 1d slabs, 2d pencils, or 3d bricks depending on which `binstyle` is used. The simulation box is partitioned conceptually into `Nx` by `Ny` by `Nz` bins. Depending on the `binstyle`, you may only specify one or two of these values; the others are effectively set to 1 (no binning in that dimension). For non-orthogonal (triclinic) simulation boxes, the bins are “tilted” slabs or pencils that are parallel to the tilted faces of the box. See the `region prism` command for a discussion of the geometry of tilted boxes in LAMMPS.

When a temperature is computed, the center-of-mass velocity for the set of atoms that are both in the compute group and in the same spatial bin is calculated. This bias velocity is then subtracted from the velocities of individual atoms in the bin to yield a thermal velocity for each atom. Note that if there is only one atom in the bin, its thermal velocity will thus be 0.0.

After the spatially-averaged velocity field has been subtracted from each atom, the temperature is calculated by the formula $KE = \left(\frac{1}{2} \cdot \text{dim} \cdot N - Ns \cdot Nx \cdot Ny \cdot Nz - \text{extra}\right) \cdot k \cdot T / 2$, where $KE$ = total kinetic energy of the group of atoms (sum of $1/2 m v^2$), $\text{dim}$ = 2 or 3 = dimensionality of the simulation, $Ns$ = 0, 1, 2 or 3 for streaming velocity subtracted in 0, 1, 2 or 3 dimensions, $\text{extra}$ = extra degrees-of-freedom, $N$ = number of atoms in the group, $k$ = Boltzmann constant, and $T$ = temperature. The $Ns \cdot Nx \cdot Ny \cdot Nz$ term is degrees of freedom subtracted to adjust for the removal of the center-of-mass velocity in each direction of the $Nx \cdot Ny \cdot Nz$ bins, as discussed in the (Evans) paper. The `extra` term defaults to $(\text{dim} - Ns)$ and accounts for overall conservation of center-of-mass velocity across the group in directions where streaming velocity is not subtracted. This can be altered using the `extra` option of the `compute_modify` command.

If the `out` keyword is used with a `tensor` value, which is the default, a kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that $v^2$ is replaced by $vx*vy$ for the xy component, etc. The 6 components of the vector are ordered $xx$, $yy$, $zz$, $xy$, $xz$, $yz$.

If the `out` keyword is used with a `bin` value, the count of atoms and computed temperature for each bin are stored for output, as an array of values, as described below. The temperature of each bin is calculated as described above, where the bias velocity is subtracted and only the remaining thermal velocity of atoms in the bin contributes to the temperature. See the note below for how the temperature is normalized by the degrees-of-freedom of atoms in the bin.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the `dynamic` option of the `compute_modify` command if this is not the case.

The removal of the spatially-averaged velocity field by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostating then this bias will be subtracted from each atom, thermostating of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostating fixes that work in this way include `fix nvt`, `fix temp/rescale`, `fix temp/berendsen`, and `fix langevin`.  

18.142. compute temp/profile command
This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as *fix shake* and *fix rigid*. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the *extra* option of the *compute_modify* command.

**Note:** When using the *out* keyword with a value of *bin*, the calculated temperature for each bin includes the degrees-of-freedom adjustment described in the preceding paragraph for fixes that constrain molecular motion, as well as the adjustment due to the *extra* option (which defaults to *dim - Ns* as described above), by fractionally applying them based on the fraction of atoms in each bin. As a result, the bin degrees-of-freedom summed over all bins exactly equals the degrees-of-freedom used in the scalar temperature calculation, $\Sigma N_{DOF,i} = N_{DOF}$ and the corresponding relation for temperature is also satisfied $\Sigma N_{DOF,i}T_i = N_{DOF}T$. These relations will breakdown in cases where the adjustment exceeds the actual number of degrees-of-freedom in a bin. This could happen if a bin is empty or in situations where rigid molecules are non-uniformly distributed, in which case the reported temperature within a bin may not be accurate.

See the *Howto thermostat* page for a discussion of different ways to compute temperature and perform thermostatting. Using this compute in conjunction with a thermostatting fix, as explained there, will effectively implement a profile-unbiased thermostat (PUT), as described in *(Evans)*.

### 18.142.4 Output info

This compute calculates a global scalar (the temperature). Depending on the setting of the *out* keyword, it also calculates a global vector or array. For *out = tensor*, it calculates a vector of length 6 (KE tensor), which can be accessed by indices 1-6. For *out = bin* it calculates a global array which has 2 columns and N rows, where N is the number of bins. The first column contains the number of atoms in that bin. The second contains the temperature of that bin, calculated as described above. The ordering of rows in the array is as follows. Bins in x vary fastest, then y, then z. Thus for a 10x10x10 3d array of bins, there will be 1000 rows. The bin with indices $i_x,i_y,i_z = 2,3,4$ would map to row $M = (i_z-1)*10^2 + (i_y-1)*10 + i_x = 322$, where the rows are numbered from 1 to 1000 and the bin indices are numbered from 1 to 10 in each dimension.

These values can be used by any command that uses global scalar or vector or array values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”. The array values are “intensive”.

The scalar value will be in temperature *units*. The vector values will be in energy *units*. The first column of array values are counts; the values in the second column will be in temperature *units*. 

---

*LAMMPS Documentation, Release patch 23Jun2022*
18.142.5 Restrictions

You should not use too large a velocity-binning grid, especially in 3d. In the current implementation, the binned velocity averages are summed across all processors, so this will be inefficient if the grid is too large, and the operation is performed every timestep, as it will be for most thermostats.

18.142.6 Related commands

18.143 compute temp/ramp command

18.143.1 Syntax

```
compute ID group-ID temp/ramp vdim vlo vhi dim clo chi keyword value ...
```

- ID, group-ID are documented in `compute` command
- temp/ramp = style name of this compute command
- vdim = vx or vy or vz
- vlo,vhi = subtract velocities between vlo and vhi (velocity units)
- dim = x or y or z
- clo,chi = lower and upper bound of domain to subtract from (distance units)
- zero or more keyword/value pairs may be appended
- keyword = units

units value = lattice or box

18.143.2 Examples

```
compute 2nd middle temp/ramp vx 0 8 y 2 12 units lattice
```
18.143.3 Description

Define a computation that calculates the temperature of a group of atoms, after subtracting out an ramped velocity profile before computing the kinetic energy. A compute of this style can be used by any command that computes a temperature, e.g. `thermo_modify`, `fix temp/rescale`, `fix npt`, etc.

The meaning of the arguments for this command which define the velocity ramp are the same as for the `velocity ramp` command which was presumably used to impose the velocity.

After the ramp velocity has been subtracted from the specified dimension for each atom, the temperature is calculated by the formula $KE = \frac{dim}{2} N k T$, where $KE$ = total kinetic energy of the group of atoms (sum of $\frac{1}{2} m v^2$), $dim = 2$ or $3$ = dimensionality of the simulation, $N$ = number of atoms in the group, $k = \text{Boltzmann constant}$, and $T = \text{temperature}$.

The `units` keyword determines the meaning of the distance units used for coordinates ($c1,c2$) and velocities ($vlo,vhi$). A `box` value selects standard distance units as defined by the `units` command, e.g. Angstroms for `units = real` or `metal`. A `lattice` value means the distance units are in lattice spacings; e.g. velocity = lattice spacings / $\tau$. The `lattice` command must have been previously used to define the lattice spacing.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that $v^2$ is replaced by $vx*vy$ for the xy component, etc. The 6 components of the vector are ordered $xx,yy,zz,xy,xz,yz$.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the `dynamic` option of the `compute_modify` command if this is not the case.

The removal of the ramped velocity component by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostatting then this bias will be subtracted from each atom, thermostatting of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostatting fixes that work in this way include `fix nvt`, `fix temp/rescale`, `fix temp/berendsen`, and `fix langevin`.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as `fix shake` and `fix rigid`. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the `extra` option of the `compute_modify` command.

See the `Howto thermostat` page for a discussion of different ways to compute temperature and perform thermostatting.

18.143.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the `Howto output` page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature `units`. The vector values will be in energy `units`.

18.143.5 Restrictions

`none`
18.143.6 Related commands

The option default is units = lattice.

18.144 compute temp/region command

18.144.1 Syntax

```
compute ID group-ID temp/region region-ID
```

- ID, group-ID are documented in `compute` command
- `temp/region` = style name of this compute command
- `region-ID` = ID of region to use for choosing atoms

18.144.2 Examples

```
compute mine flow temp/region boundary
```

18.144.3 Description

Define a computation that calculates the temperature of a group of atoms in a geometric region. This can be useful for thermostatting one portion of the simulation box. E.g. a McDLT simulation where one side is cooled, and the other side is heated. A compute of this style can be used by any command that computes a temperature, e.g. `thermo_modify`, `fix temp/rescale`, etc.

Note that a `region`-style temperature can be used to thermostat with `fix temp/rescale` or `fix langevin`, but should probably not be used with Nose/Hoover style fixes (`fix nvt`, `fix npt`, or `fix nph`), if the degrees-of-freedom included in the computed T varies with time.

The temperature is calculated by the formula $KE = \frac{dim}{2} N k T$, where $KE = \text{total kinetic energy of the group of atoms (sum of } 1/2 m v^2)$, $dim = 2$ or $3 = \text{dimensionality of the simulation}$, $N = \text{number of atoms in both the group and region}$, $k = \text{Boltzmann constant}$, and $T = \text{temperature}$.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that $v^2$ is replaced by $vx*vy$ for the $xy$ component, etc. The 6 components of the vector are ordered $xx$, $yy$, $zz$, $xy$, $xz$, $yz$.

The number of atoms contributing to the temperature is calculated each time the temperature is evaluated since it is assumed atoms can enter/leave the region. Thus there is no need to use the `dynamic` option of the `compute_modify` command for this compute style.

The removal of atoms outside the region by this fix is essentially computing the temperature after a “bias” has been removed, which in this case is the velocity of any atoms outside the region. If this compute is used with a fix command that performs thermostatting then this bias will be subtracted from each atom, thermostatting of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostatting fixes that work in this way include `fix nvt`, `fix temp/rescale`, `fix temp/berendsen`, and `fix langevin`. This means that when this compute is used to calculate the
temperature for any of the thermostatting fixes via the `fix modify temp` command, the thermostat will operate only on atoms that are currently in the geometric region.

Unlike other compute styles that calculate temperature, this compute does not subtract out degrees-of-freedom due to fixes that constrain motion, such as `fix shake` and `fix rigid`. This is because those degrees of freedom (e.g. a constrained bond) could apply to sets of atoms that straddle the region boundary, and hence the concept is somewhat ill-defined. If needed the number of subtracted degrees-of-freedom can be set explicitly using the `extra` option of the `compute_modify` command.

See the `Howto thermostat` page for a discussion of different ways to compute temperature and perform thermostatting.

### 18.144.4 Output info

18.146.3 Description

Define a computation that calculates the temperature of a group of atoms, after subtracting out the center-of-mass velocity and angular velocity of the group. This is useful if the group is expected to have a non-zero net velocity and/or global rotation motion for some reason. A compute of this style can be used by any command that computes a temperature, e.g. `thermo_modify`, `fix temp/rescale`, `fix npt`, etc.

After the center-of-mass velocity and angular velocity has been subtracted from each atom, the temperature is calculated by the formula \( KE = \text{dim}/2 \cdot N \cdot k \cdot T \), where \( KE \) = total kinetic energy of the group of atoms (sum of \( 1/2 m v^2 \)), \( \text{dim} = 2 \) or \( 3 \) = dimensionality of the simulation, \( N \) = number of atoms in the group, \( k \) = Boltzmann constant, and \( T \) = temperature.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that \( v^2 \) is replaced by \( v_x^2 v_y \) for the \( xy \) component, etc. The 6 components of the vector are ordered \( xx, yy, zz, xy, xz, yz \).

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the `dynamic` option of the `compute_modify` command if this is not the case.

The removal of the center-of-mass velocity and angular velocity by this fix is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostatting then this bias will be subtracted from each atom, thermostatting of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostatting fixes that work in this way include `fix nvt`, `fix temp/rescale`, `fix temp/berendsen`, and `fix langevin`.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as `fix shake` and `fix rigid`. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the `extra` option of the `compute_modify` command.

See the Howto thermostat page for a discussion of different ways to compute temperature and perform thermostatting.

18.147.2 Examples

```
compute 1 all temp/sphere
compute myTemp mobile temp/sphere bias tempCOM
compute myTemp mobile temp/sphere dof rotate
```

18.147.3 Description

Define a computation that calculates the temperature of a group of spherical particles, including a contribution from both their translational and rotational kinetic energy. This differs from the usual `compute temp` command, which assumes point particles with only translational kinetic energy.

Both point and finite-size particles can be included in the group. Point particles do not rotate, so they have only 3 translational degrees of freedom. For 3d spherical particles, each has 6 degrees of freedom (3 translational, 3 rotational). For 2d spherical particles, each has 3 degrees of freedom (2 translational, 1 rotational).

**Note:** This choice for degrees of freedom (dof) assumes that all finite-size spherical particles in your model will freely rotate, sampling all their rotational dof. It is possible to use a combination of interaction potentials and fixes that induce no torque or otherwise constrain some of all of your particles so that this is not the case. Then there are less dof and you should use the `compute_modify extra` command to adjust the dof accordingly.
The translational kinetic energy is computed the same as is described by the `compute temp` command. The rotational kinetic energy is computed as $1/2 I w^2$, where $I$ is the moment of inertia for a sphere and $w$ is the particle’s angular velocity.

**Note:** For 2d models, particles are treated as spheres, not disks, meaning their moment of inertia will be the same as in 3d.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute. The formula for the components of the tensor is the same as the above formulas, except that $v^2$ and $w^2$ are replaced by $vx*vy$ and $wx*wy$ for the xy component. The 6 components of the vector are ordered xx, yy, zz, xy, xz, yz.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the `dynamic` option of the `compute_modify` command if this is not the case.

This compute subtracts out translational degrees-of-freedom due to fixes that constrain molecular motion, such as `fix shake` and `fix rigid`. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the `extra` option of the `compute_modify` command.

See the *Howto thermostat* page for a discussion of different ways to compute temperature and perform thermostatting.

The keyword/value option pairs are used in the following ways.

For the `bias` keyword, `bias-ID` refers to the ID of a temperature compute that removes a “bias” velocity from each atom. This allows `compute temp/sphere` to compute its thermal temperature after the translational kinetic energy components have been altered in a prescribed way, e.g. to remove a flow velocity profile. Thermostats that use this compute will work with this bias term. See the doc pages for individual computes that calculate a temperature and the doc pages for fixes that perform thermostatting for more details.

For the `dof` keyword, a setting of `all` calculates a temperature that includes both translational and rotational degrees of freedom. A setting of `rotate` calculates a temperature that includes only rotational degrees of freedom.

### 18.147.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 6 (KE tensor), which can be accessed by indices 1-6. These values can be used by any command that uses global scalar or vector values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The vector values are “extensive”.

The scalar value will be in temperature units. The vector values will be in energy units.

### 18.147.5 Restrictions

This fix requires that atoms store torque and angular velocity (omega) and a radius as defined by the `atom_style sphere` command.

All particles in the group must be finite-size spheres, or point particles with radius = 0.0.
18.147.6 Related commands

compute temp, compute temp/asphere

18.147.7 Default

The option defaults are no bias and dof = all.

18.148 compute temp/uef command

18.148.1 Syntax

compute ID group-ID temp/uef

- ID, group-ID are documented in compute command
- temp/uef = style name of this compute command

18.148.2 Examples

compute 1 all temp/uef
compute 2 sel temp/uef

18.148.3 Description

This command is used to compute the kinetic energy tensor in the reference frame of the applied flow field when fix nvt/uef or fix npt/uef is used. It is not necessary to use this command to compute the scalar value of the temperature. A compute temp may be used for that purpose.

Output information for this command can be found in the documentation for compute temp.

18.148.4 Restrictions

This fix is part of the UEF package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This command can only be used when fix nvt/uef or fix npt/uef is active.

compute 1 all ti lj/cut 1*3 v_lj v_dlj coul/long 2*3 v_c v_dc kspace 1*3 v_ks v_dks

18.149.3 Description

Define a computation that calculates the derivative of the interaction potential with respect to lambda, the coupling parameter used in a thermodynamic integration. This derivative can be used to infer a free energy difference resulting from an alchemical simulation, as described in Eike.

Typically this compute will be used in conjunction with the fix adapt command which can perform alchemical transformations by adjusting the strength of an interaction potential as a simulation runs, as defined by one or more pair_style or kspace_style commands. This scaling is done via a prefactor on the energy, forces, virial calculated by the pair or K-Space style. The prefactor is often a function of a lambda parameter which may be adjusted from 0 to 1 (or vice versa) over the course of a run. The time-dependent adjustment is what the fix adapt command does.

Assume that the unscaled energy of a pair_style or kspace_style is given by U. Then the scaled energy is
Us = f(\lambda) U

where f() is some function of \lambda. What this compute calculates is

\[ \frac{dU_s}{d(\lambda)} = U \frac{df(\lambda)}{d\lambda} = \frac{Us}{f(\lambda)} \frac{df(\lambda)}{d\lambda} \]

which is the derivative of the system’s scaled potential energy Us with respect to \lambda.

To perform this calculation, you provide one or more atom types as atype. Atype can be specified in one of two ways. An explicit numeric values can be used, as in the first example above. Or a wildcard asterisk can be used in place of or in conjunction with the atype argument to select multiple atom types. This takes the form “*” or “*n” or “n*” or “m*n”. If N = the number of atom types, then an asterisk with no numeric values means all types from 1 to N. A leading asterisk means all types from 1 to n (inclusive). A trailing asterisk means all types from n to N (inclusive). A middle asterisk means all types from m to n (inclusive).

You also specify two functions, as equal-style variables. The first is specified as v_{name1}, where name1 is the name of the variable, and is f(\lambda) in the notation above. The second is specified as v_{name2}, where name2 is the name of the variable, and is df(\lambda)/d\lambda in the notation above. I.e. it is the analytic derivative of f() with respect to \lambda. Note that the name1 variable is also typically given as an argument to the fix adapt command.

An alchemical simulation may use several pair potentials together, invoked via the pair_style hybrid or hybrid/overlay command. The total dUs/d\lambda for the overall system is calculated as the sum of each contributing term as listed by the keywords in the compute ti command. Individual pair potentials can be listed, which will be sub-styles in the hybrid case. You can also include a K-space term via the kspace keyword. You can also include a pairwise long-range tail correction to the energy via the tail keyword.

For each term you can specify a different (or the same) scale factor by the two variables that you list. Again, these will typically correspond to the scale factors applied to these various potentials and the K-Space contribution via the fix adapt command.

More details about the exact functional forms for the computation of du/dl can be found in the paper by Eike.

18.149.4 Output info

This compute calculates a global scalar, namely dUs/d\lambda. This value can be used by any command that uses a global scalar value from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “extensive”.

The scalar value will be in energy units.

18.150 compute torque/chunk command

18.150.1 Syntax

```
compute ID group-ID torque/chunk chunkID
```

- ID, group-ID are documented in `compute` command
- torque/chunk = style name of this compute command
- chunkID = ID of `compute chunk/atom` command

18.150.2 Examples

```
compute 1 fluid torque/chunk molchunk
```

18.150.3 Description

Define a computation that calculates the torque on multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a `compute chunk/atom` command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the `compute chunk/atom` and `Howto chunk` doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the 3 components of the torque vector for each chunk, due to the forces on the individual atoms in the chunk around the center-of-mass of the chunk. The calculation includes all effects due to atoms passing through periodic boundaries.

Note that only atoms in the specified group contribute to the calculation. The `compute chunk/atom` command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

Note: The coordinates of an atom contribute to the chunk’s torque in “unwrapped” form, by using the image flags associated with each atom. See the `dump custom` command for a discussion of “unwrapped” coordinates. See the Atoms section of the `read_data` command for a discussion of image flags and how they are set for each atom. You can reset the image flags (e.g. to 0) before invoking this compute by using the `set image` command.

1872 Chapter 18. Computes
The simplest way to output the results of the compute torque/chunk calculation to a file is to use the `fix ave/time` command, for example:

```plaintext
compute cc1 all chunk/atom molecule
compute myChunk all torque/chunk cc1
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
```

### 18.150.4 Output info

This compute calculates a global array where the number of rows = the number of chunks $N_{chunk}$ as calculated by the specified `compute chunk/atom` command. The number of columns = 3 for the 3 xyz components of the torque for each chunk. These values can be accessed by any command that uses global array values from a compute as input. See the `Howto output` doc page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in force-distance units.

### 18.151 compute vacf command

#### 18.151.1 Syntax

```plaintext
compute ID group-ID vacf
```

- ID, group-ID are documented in `compute` command
- `vacf` = style name of this compute command

#### 18.151.2 Examples

```plaintext
compute 1 all vacf
compute 1 upper vacf
```
18.151.3 Description

Define a computation that calculates the velocity auto-correlation function (VACF), averaged over a group of atoms. Each atom’s contribution to the VACF is its current velocity vector dotted into its initial velocity vector at the time the compute was specified.

A vector of four quantities is calculated by this compute. The first 3 elements of the vector are $v_x \cdot v_x0$ (and similarly for the y and z components), summed and averaged over atoms in the group. $v_x$ is the current x-component of velocity for the atom, $v_x0$ is the initial x-component of velocity for the atom. The fourth element of the vector is the total VACF, i.e. $(v_xv_x0 + v_yv_y0 + v_zv_z0)$, summed and averaged over atoms in the group.

The integral of the VACF versus time is proportional to the diffusion coefficient of the diffusing atoms. This can be computed in the following manner, using the `variable trap()` function:

```plaintext
compute   2 all vacf
fix       5 all vector l c_2[4]
variable  diff equal dt*trap(f_5)
thermo_style custom step v_diff
```

Note: If you want the quantities calculated by this compute to be continuous when running from a restart file, then you should use the same ID for this compute, as in the original run. This is so that the fix this compute creates to store per-atom quantities will also have the same ID, and thus be initialized correctly with time=0 atom velocities from the restart file.

18.151.4 Output info

This compute calculates a global vector of length 4, which can be accessed by indices 1-4 by any command that uses global vector values from a compute as input. See the Howto output doc page for an overview of LAMMPS output options.

The vector values are “intensive”. The vector values will be in velocity^2 units.

- chunkID = ID of `compute chunk/atom` command

18.152.2 Examples

```
compute 1 fluid vcm/chunk molchunk
```

18.152.3 Description

Define a computation that calculates the center-of-mass velocity for multiple chunks of atoms.

In LAMMPS, chunks are collections of atoms defined by a `compute chunk/atom` command, which assigns each atom to a single chunk (or no chunk). The ID for this command is specified as chunkID. For example, a single chunk could be the atoms in a molecule or atoms in a spatial bin. See the `compute chunk/atom` and `Howto chunk` doc pages for details of how chunks can be defined and examples of how they can be used to measure properties of a system.

This compute calculates the x,y,z components of the center-of-mass velocity for each chunk. This is done by summing mass*velocity for each atom in the chunk and dividing the sum by the total mass of the chunk.

Note that only atoms in the specified group contribute to the calculation. The `compute chunk/atom` command defines its own group; atoms will have a chunk ID = 0 if they are not in that group, signifying they are not assigned to a chunk, and will thus also not contribute to this calculation. You can specify the “all” group for this command if you simply want to include atoms with non-zero chunk IDs.

The simplest way to output the results of the compute vcm/chunk calculation to a file is to use the `fix ave/time` command, for example:

```
compute ccl all chunk/atom molecule
compute myChunk all vcm/chunk ccl
fix 1 all ave/time 100 1 100 c_myChunk[*] file tmp.out mode vector
```

18.152.4 Output info

This compute calculates a global array where the number of rows = the number of chunks $N_{chunk}$ as calculated by the specified `compute chunk/atom` command. The number of columns = 3 for the x,y,z center-of-mass velocity coordinates of each chunk. These values can be accessed by any command that uses global array values from a compute as input. See the `Howto output` page for an overview of LAMMPS output options.

The array values are “intensive”. The array values will be in velocity `units`.

variable V equal c_cos[7]
variable A equal 0.02E-5  # A/fs^2
variable density equal density
variable lz equal lz
variable reciprocalViscosity equal v_V/${A}/v_density*39.4784/v_lz/v_lz*100  # 1/(Pa*s)

18.153.3 Description

Define a computation that calculates the velocity amplitude of a group of atoms with a cosine-shaped velocity profile and the temperature of them after subtracting out the velocity profile before computing the kinetic energy. A compute of this style can be used by any command that computes a temperature, e.g. thermo_modify, fix npt, etc.

This command together with fix_accelerate/cos enables viscosity calculation with periodic perturbation method, as described by Hess. An acceleration along the x-direction is applied to the simulation system by using fix_accelerate/cos command. The acceleration is a periodic function along the z-direction:

\[ a_x(z) = A \cos \left( \frac{2\pi z}{l_z} \right) \]

where \( A \) is the acceleration amplitude, \( l_z \) is the z-length of the simulation box. At steady state, the acceleration generates a velocity profile:

\[ v_x(z) = V \cos \left( \frac{2\pi z}{l_z} \right) \]
The generated velocity amplitude $V$ is related to the shear viscosity $\eta$ by:

$$V = \frac{A \rho}{\eta} \left( \frac{l_z}{2\pi} \right)^2$$

and it can be obtained from ensemble average of the velocity profile:

$$V = \frac{\sum_i 2m_i v_{i,x} \cos \left( \frac{2\pi z_i}{l_z} \right)}{\sum_i m_i}$$

where $m_i$, $v_{i,x}$ and $z_i$ are the mass, x-component velocity and z coordinate of a particle.

After the cosine-shaped collective velocity in $x$ direction has been subtracted for each atom, the temperature is calculated by the formula $KE = \frac{dim}{2} N k T$, where $KE = \text{total kinetic energy of the group of atoms (sum of } 1/2 m v^2)$, $dim = 2$ or $3 = \text{dimensionality of the simulation}$, $N = \text{number of atoms in the group}$, $k = \text{Boltzmann constant}$, and $T = \text{temperature}$.

A kinetic energy tensor, stored as a 6-element vector, is also calculated by this compute for use in the computation of a pressure tensor. The formula for the components of the tensor is the same as the above formula, except that $v^2$ is replaced by $v_x v_y$ for the xy component, etc. The 6 components of the vector are ordered xx, yy, zz, xy, xz, yz.

The number of atoms contributing to the temperature is assumed to be constant for the duration of the run; use the dynamic option of the compute_modify command if this is not the case. However, in order to get meaningful result, the group ID of this compute should be all.

The removal of the cosine-shaped velocity component by this command is essentially computing the temperature after a “bias” has been removed from the velocity of the atoms. If this compute is used with a fix command that performs thermostatting then this bias will be subtracted from each atom, thermostatting of the remaining thermal velocity will be performed, and the bias will be added back in. Thermostatting fixes that work in this way include fix nvt, fix temp/rescale, fix temp/berendsen, and fix langevin.

This compute subtracts out degrees-of-freedom due to fixes that constrain molecular motion, such as fix shake and fix rigid. This means the temperature of groups of atoms that include these constraints will be computed correctly. If needed, the subtracted degrees-of-freedom can be altered using the extra option of the compute_modify command.

See the Howto thermostat page for a discussion of different ways to compute temperature and perform thermostatting.

18.153.4 Output info

This compute calculates a global scalar (the temperature) and a global vector of length 7, which can be accessed by indices 1-7. The first 6 elements of the vector are the KE tensor, and the 7-th is the cosine-shaped velocity amplitude $V$, which can be used to calculate the reciprocal viscosity, as shown in the example. These values can be used by any command that uses global scalar or vector values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The scalar value calculated by this compute is “intensive”. The first 6 elements of vector values are “extensive”, and the 7-th element of vector values is “intensive”.

The scalar value will be in temperature units. The first 6 elements of vector values will be in energy units. The 7-th element of vector value will be in velocity units.
18.153.5 Restrictions

This command is only available when LAMMPS was built with the MISC package. Since this compute depends on `fix accelerate/cos` which can only work for 3d systems, it cannot be used for 2d systems.

compute 3b precipitate voronoi/atom radius v_r
compute 4 solute voronoi/atom only_group
compute 5 defects voronoi/atom occupation
compute 6 all voronoi/atom neighbors yes
```

18.154.3 Description

Define a computation that calculates the Voronoi tessellation of the atoms in the simulation box. The tessellation is calculated using all atoms in the simulation, but non-zero values are only stored for atoms in the group.

By default two per-atom quantities are calculated by this compute. The first is the volume of the Voronoi cell around each atom. Any point in an atom’s Voronoi cell is closer to that atom than any other. The second is the number of faces of the Voronoi cell. This is equal to the number of nearest neighbors of the central atom, plus any exterior faces (see note below). If the `peratom` keyword is set to “no”, the per-atom quantities are still calculated, but they are not accessible.

If the `only_group` keyword is specified the tessellation is performed only with respect to the atoms contained in the compute group. This is equivalent to deleting all atoms not contained in the group prior to evaluating the tessellation.

If the `surface` keyword is specified a third quantity per atom is computed: the Voronoi cell surface of the given atom. `surface` takes a group ID as an argument. If a group other than `all` is specified, only the Voronoi cell facets facing a neighbor atom from the specified group are counted towards the surface area.

In the example above, a precipitate embedded in a matrix, only atoms at the surface of the precipitate will have non-zero surface area, and only the outward facing facets of the Voronoi cells are counted (the hull of the precipitate). The total surface area of the precipitate can be obtained by running a “reduce sum” compute on c_2[3]

If the `radius` keyword is specified with an atom style variable as the argument, a poly-disperse Voronoi tessellation is performed. Examples for radius variables are

```
variable r1 atom (type==1)*0.1+(type==2)*0.4
compute radius all property/atom radius
variable r2 atom c_radius
```

Here v_r1 specifies a per-type radius of 0.1 units for type 1 atoms and 0.4 units for type 2 atoms, and v_r2 accesses the radius property present in atom_style sphere for granular models.

The `edge_histo` keyword activates the compilation of a histogram of number of edges on the faces of the Voronoi cells in the compute group. The argument `maxedge` of the this keyword is the largest number of edges on a single Voronoi cell face expected to occur in the sample. This keyword adds the generation of a global vector with `maxedge+1` entries. The last entry in the vector contains the number of faces with more than `maxedge` edges. Since the polygon with the smallest amount of edges is a triangle, entries 1 and 2 of the vector will always be zero.

The `edge_threshold` and `face_threshold` keywords allow the suppression of edges below a given minimum length and faces below a given minimum area. Ultra short edges and ultra small faces can occur as artifacts of the Voronoi tessellation. These keywords will affect the neighbor count and edge histogram outputs.

If the `occupation` keyword is specified the tessellation is only performed for the first invocation of the compute and then stored. For all following invocations of the compute the number of atoms in each Voronoi cell in the stored tessellation is counted. In this mode the compute returns a per-atom array with 2 columns. The first column is the number of atoms currently in the Voronoi volume defined by this atom at the time of the first invocation of the compute (note that the
atom may have moved significantly). The second column contains the total number of atoms sharing the Voronoi cell of the stored tessellation at the location of the current atom. Numbers in column one can be any positive integer including zero, while column two values will always be greater than zero. Column one data can be used to locate vacancies (the coordinates are given by the atom coordinates at the time step when the compute was first invoked), while column two data can be used to identify interstitial atoms.

If the neighbors value is set to yes, then this compute creates a local array with 3 columns. There is one row for each face of each Voronoi cell. The 3 columns are the atom ID of the atom that owns the cell, the atom ID of the atom in the neighboring cell (or zero if the face is external), and the area of the face. The array can be accessed by any command that uses local values from a compute as input. See the Howto output page for an overview of LAMMPS output options. More specifically, the array can be accessed by a dump local command to write a file containing all the Voronoi neighbors in a system:

```
compute 6 all voronoi/atom neighbors yes
```

If the face_threshold keyword is used, then only faces with areas greater than the threshold are stored.

The Voronoi calculation is performed by the freely available Voro++ package, written by Chris Rycroft at UC Berkeley and LBL, which must be installed on your system when building LAMMPS for use with this compute. See instructions on obtaining and installing the Voro++ software in the src/VORONOI/README file.

**Note:** The calculation of Voronoi volumes is performed by each processor for the atoms it owns, and includes the effect of ghost atoms stored by the processor. This assumes that the Voronoi cells of owned atoms are not affected by atoms beyond the ghost atom cut-off distance. This is usually a good assumption for liquid and solid systems, but may lead to underestimation of Voronoi volumes in low density systems. By default, the set of ghost atoms stored by each processor is determined by the cutoff used for pair_style interactions. The cutoff can be set explicitly via the comm_modify cutoff command. The Voronoi cells for atoms adjacent to empty regions will extend into those regions up to the communication cutoff in x, y, or z. In that situation, an exterior face is created at the cutoff distance normal to the x, y, or z direction. For triclinic systems, the exterior face is parallel to the corresponding reciprocal lattice vector.

**Note:** The Voro++ package performs its calculation in 3d. This will still work for a 2d LAMMPS simulation, provided all the atoms have the same z coordinate. The Voronoi cell of each atom will be a columnar polyhedron with constant cross-sectional area along the z direction and two exterior faces at the top and bottom of the simulation box. If the atoms do not all have the same z coordinate, then the columnar cells will be accordingly distorted. The cross-sectional area of each Voronoi cell can be obtained by dividing its volume by the z extent of the simulation box. Note that you define the z extent of the simulation box for 2d simulations when using the create_box or read_data commands.

### 18.154.4 Output info

By default, this compute calculates a per-atom array with 2 columns. In regular dynamic tessellation mode the first column is the Voronoi volume, the second is the neighbor count, as described above (read above for the output data in case the occupation keyword is specified). These values can be accessed by any command that uses per-atom values from a compute as input. See the Howto output page for an overview of LAMMPS output options. If the peratom keyword is set to “no”, the per-atom array is still created, but it is not accessible.

If the edge_histo keyword is used, then this compute generates a global vector of length maxedge+1, containing a histogram of the number of edges per face.

If the neighbors value is set to yes, then this compute calculates a local array with 3 columns. There is one row for each face of each Voronoi cell.

1880 Chapter 18. Computes
Note: Some LAMMPS commands such as the compute reduce command can accept either a per-atom or local quantity. If this compute produces both quantities, the command may access the per-atom quantity, even if you want to access the local quantity. This effect can be eliminated by using the peratom keyword to turn off the production of the per-atom quantities. For the default value yes both quantities are produced. For the value no, only the local array is produced.

The Voronoi cell volume will be in distance units cubed. The Voronoi face area will be in distance units squared.

18.154.5 Restrictions

This compute is part of the VORONOI package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

It also requires you have a copy of the Voro++ library built and installed on your system. See instructions on obtaining and installing the Voro++ software in the src/VORONOI/README file.

18.155 compute xrd command

18.155.1 Syntax

compute ID group-ID xrd lambda type1 type2 ... typeN keyword value ...

- ID, group-ID are documented in compute command
- xrd = style name of this compute command
- lambda = wavelength of incident radiation (length units)
- type1 type2 ... typeN = chemical symbol of each atom type (see valid options below)
- zero or more keyword/value pairs may be appended
- keyword = 2Theta or c or LP or manual or echo
  - 2Theta values = Min2Theta Max2Theta
    - Min2Theta, Max2Theta = minimum and maximum 2 theta range to explore
      (radians or degrees)
    - c values = c1 c2 c3
      - c1, c2, c3 = parameters to adjust the spacing of the reciprocal lattice nodes in the h, k, and l directions respectively
  - c = switch to apply Lorentz-polarization factor
    - 0/1 = off/on
  - manual = flag to use manual spacing of reciprocal lattice points based on the values of the c parameters
**echo** = flag to provide extra output for debugging purposes

### 18.155.2 Examples

```

compute 2 all xrd 1.541838 Al 0 2Theta 10 100 c 0.05 0.05 0.05 LP 1 manual

fix 1 all ave/histo/weight 111 0.087 0.87 250 c_1[1] c_1[2] mode vector file Rad2Theta.xrd
fix 2 all ave/histo/weight 111 10 100 250 c_2[1] c_2[2] mode vector file Deg2Theta.xrd
```

### 18.155.3 Description

Define a computation that calculates x-ray diffraction intensity as described in (Coleman) on a mesh of reciprocal lattice nodes defined by the entire simulation domain (or manually) using a simulated radiation of wavelength \( \lambda \).

The x-ray diffraction intensity, \( I \), at each reciprocal lattice point, \( k \), is computed from the structure factor, \( F \), using the equations:

\[
I = L_p(\theta) \frac{F^*F}{N}
\]

\[
F(k) = \sum_{j=1}^{N} f_j(\theta) \exp(2\pi i k \cdot r_j)
\]

\[
L_p(\theta) = \frac{1 + \cos^2(2\theta)}{\cos(\theta)\sin^2(\theta)}
\]

\[
\frac{\sin(\theta)}{\lambda} = \frac{|k|}{2}
\]

Here, \( K \) is the location of the reciprocal lattice node, \( r_j \) is the position of each atom, \( f_j \) are atomic scattering factors, \( L_p \) is the Lorentz-polarization factor, and \( \theta \) is the scattering angle of diffraction. The Lorentz-polarization factor can be turned off using the optional **LP** keyword.

Diffraction intensities are calculated on a three-dimensional mesh of reciprocal lattice nodes. The mesh spacing is defined either (a) by the entire simulation domain or (b) manually using selected values as shown in the 2D diagram below.

For a mesh defined by the simulation domain, a rectilinear grid is constructed with spacing \( c^*\text{inv}(A) \) along each reciprocal lattice axis. Where \( A \) are the vectors corresponding to the edges of the simulation cell. If one or two directions has non-periodic boundary conditions, then the spacing in these directions is defined from the average of the (inversed) box lengths with periodic boundary conditions. Meshes defined by the simulation domain must contain at least one periodic boundary.

If the **manual** flag is included, the mesh of reciprocal lattice nodes will defined using the \( c \) values for the spacing along each reciprocal lattice axis. Note that manual mapping of the reciprocal space mesh is good for comparing diffraction results from multiple simulations; however it can reduce the likelihood that Bragg reflections will be satisfied unless small spacing parameters (< 0.05 Angstrom\(^{-1}\)) are implemented. Meshes with manual spacing do not require a periodic boundary.

The limits of the reciprocal lattice mesh are determined by range of scattering angles explored. The **2Theta** parameters allows the user to reduce the scattering angle range to only the region of interest which reduces the cost of the computation.
The atomic scattering factors, \( f_j \), accounts for the reduction in diffraction intensity due to Compton scattering. Compute xrd uses analytical approximations of the atomic scattering factors that vary for each atom type (type1 type2 ... typeN) and angle of diffraction. The analytic approximation is computed using the formula (Colliex):

\[
f_j \left( \frac{\sin(\theta)}{\lambda} \right) = \sum_{i} a_i \exp \left( -b_i \frac{\sin^2(\theta)}{\lambda^2} \right) + c
\]

Coefficients parameterized by (Peng) are assigned for each atom type designating the chemical symbol and charge of each atom type. Valid chemical symbols for compute xrd are:

If the *echo* keyword is specified, compute xrd will provide extra reporting information to the screen.

### 18.155.4 Output info

This compute calculates a global array. The number of rows in the array is the number of reciprocal lattice nodes that are explored by the mesh. The global array has 2 columns.

The first column contains the diffraction angle in the units (radians or degrees) provided with the 2*Theta* values. The second column contains the computed diffraction intensities as described above.

The array can be accessed by any command that uses global values from a compute as input. See the *Howto output* doc page for an overview of LAMMPS output options.

All array values calculated by this compute are “intensive”.

### 18.155.5 Restrictions

This compute is part of the DIFFRACTION package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

The compute xrd command does not work for triclinic cells.

### 18.155.6 Related commands

*fix ave/histo*, *compute saed*

### 18.155.7 Default

The option defaults are 2Theta = 1 179 (degrees), c = 1 1 1, LP = 1, no manual flag, no echo flag.

(Coleman) Coleman, Spearot, Capolungo, MSMSE, 21, 055020 (2013).

19.1 pair_style adp command

Accelerator Variants: adp/kk, adp/omp

19.1.1 Syntax

pair_style adp

19.1.2 Examples

pair_style adp
pair_coeff * * Ta.adp Ta
pair_coeff * * ../potentials/AlCu.adp Al Al Cu

19.1.3 Description

Style adp computes pairwise interactions for metals and metal alloys using the angular dependent potential (ADP) of (Mishin), which is a generalization of the embedded atom method (EAM) potential. The LAMMPS implementation is discussed in (Singh). The total energy $E_i$ of an atom $I$ is given by

$$
E_i = F_\alpha \left( \sum_{j \neq i} \rho_\beta (r_{ij}) \right) + \frac{1}{2} \sum_{j \neq i} \phi_{\alpha\beta}(r_{ij}) + \frac{1}{2} \sum_s (\mu_i^s)^2 + \frac{1}{2} \sum_{s,t} (\lambda_i^{st})^2 - \frac{1}{6} \nu_i^2
$$

$$
\mu_i^s = \sum_{j \neq i} u_{\alpha\beta}(r_{ij}) r_{ij}^s
$$

$$
\lambda_i^{st} = \sum_{j \neq i} w_{\alpha\beta}(r_{ij}) r_{ij}^s r_{ij}^t
$$

$$
\nu = \sum_s \lambda_i^{ss}
$$

where $F$ is the embedding energy which is a function of the atomic electron density $\rho$, $\phi$ is a pair potential interaction, $\alpha$ and $\beta$ are the element types of atoms $I$ and $J$, and $s$ and $t = 1, 2, 3$ and refer to the cartesian coordinates. The $\mu$ and $\lambda$ terms represent the dipole and quadruple distortions of the local atomic environment which extend the original EAM framework by introducing angular forces.
Note that unlike for other potentials, cutoffs for ADP potentials are not set in the pair_style or pair_coeff command; they are specified in the ADP potential files themselves. Likewise, the ADP potential files list atomic masses; thus you do not need to use the mass command to specify them.

**ADP potentials are available from:**
- The NIST WWW site at [http://www.ctcms.nist.gov/potentials](http://www.ctcms.nist.gov/potentials). Note that ADP potentials obtained from NIST must be converted into the extended DYNAMO setfl format discussed below.
- The OpenKIM Project at [https://openkim.org/browse/models/by-type](https://openkim.org/browse/models/by-type) provides ADP potentials that can be used directly in LAMMPS with the kim command interface.

Only a single pair_coeff command is used with the adp style which specifies an extended DYNAMO setfl file, which contains information for \( M \) elements. These are mapped to LAMMPS atom types by specifying \( N \) additional arguments after the filename in the pair_coeff command, where \( N \) is the number of LAMMPS atom types:

- filename
- \( N \) element names = mapping of extended setfl elements to atom types

See the pair_coeff page for alternate ways to specify the path for the potential file.

As an example, the potentials/AlCu.adp file, included in the potentials directory of the LAMMPS distribution, is an extended setfl file which has tabulated ADP values for \( w \) elements and their alloy interactions: Cu and Al. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Al, and the fourth to be Cu, you would use the following pair_coeff command:

```
pair_coeff * * AlCu.adp Al Al Al Cu
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first three Al arguments map LAMMPS atom types 1,2,3 to the Al element in the extended setfl file. The final Cu argument maps LAMMPS atom type 4 to the Al element in the extended setfl file. Note that there is no requirement that your simulation use all the elements specified by the extended setfl file.

If a mapping value is specified as NULL, the mapping is not performed. This can be used when an adp potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Adp files in the potentials directory of the LAMMPS distribution have an “.adp” suffix. A DYNAMO setfl file extended for ADP is formatted as follows. Basically it is the standard setfl format with additional tabulated functions \( u \) and \( w \) added to the file after the tabulated pair potentials. See the pair_eam command for further details on the setfl format.

- lines 1,2,3 = comments (ignored)
- line 4: \( N_{\text{elements}} \) Element1 Element2 … ElementN
- line 5: \( N_{\rho}, d_{\rho}, N_r, d_r, \text{cutoff} \)

Following the 5 header lines are \( N_{\text{elements}} \) sections, one for each element, each with the following format:

- line 1 = atomic number, mass, lattice constant, lattice type (e.g. FCC)
- embedding function \( F(\rho) \) (\( N_{\rho} \) values)
- density function \( \rho(r) \) (\( N_r \) values)

Following the \( N_{\text{elements}} \) sections, \( N_r \) values for each pair potential \( \phi(r) \) array are listed for all \( i, j \) element pairs in the same format as other arrays. Since these interactions are symmetric \( (i, j = j, i) \) only \( \phi \) arrays with \( i \geq j \) are listed, in the following order:

\[
i, j = (1, 1), (2, 1), (2, 2), (3, 1), (3, 2), (3, 3), (4, 1), \ldots, (N_{\text{elements}}, N_{\text{elements}}).
\]
The tabulated values for each φ function are listed as \( r \ast \phi \) (in units of eV-Angstroms), since they are for atom pairs, the same as for other EAM files.

After the \( \phi(r) \) arrays, each of the \( u(r) \) arrays are listed in the same order with the same assumptions of symmetry. Directly following the \( u(r) \), the \( w(r) \) arrays are listed. Note that \( \phi(r) \) is the only array tabulated with a scaling by \( r \).

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

19.1.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I \(!= J\), where types I and J correspond to two different element types, no special mixing rules are needed, since the ADP potential files specify alloy interactions explicitly.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in tabulated potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

19.1.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package.

19.1.6 Related commands

\textit{pair_coeff}, \textit{pair_eam}

19.1.7 Default

none

(Singh) Singh and Warner, Acta Mater, 58, 5797-5805 (2010),
19.2 pair_style agni command

Accelerator Variants: agni/omp

19.2.1 Syntax

```plaintext
pair_style agni
```

19.2.2 Examples

```plaintext
pair_style agni
pair_coeff * * Al.agni Al
```

19.2.3 Description

Style `agni` style computes the many-body vectorial force components for an atom as

\[
F^u_i = \sum_t^{N_t} \alpha_t \cdot \exp \left[ -\left( \frac{d^u_{i,t}}{2l} \right)^2 \right]
\]

\[
d^u_{i,t} = ||V^u_i(\eta) - V^u_t(\eta)||
\]

\[
V^u_i(\eta) = \sum_{j \neq i} \frac{r_{ij}^u}{r_{ij}} \cdot e^{-\left( \frac{r_{ij}}{\eta} \right)^2} \cdot f_d(r_{ij})
\]

\[
f_d(r_{ij}) = \frac{1}{2} \left[ \cos \left( \frac{\pi r_{ij}}{R_c} \right) + 1 \right]
\]

\(u\) labels the individual components, i.e. \(x, y\) or \(z\), and \(V\) is the corresponding atomic fingerprint. \(d\) is the Euclidean distance between any two atomic fingerprints. A total of \(N_t\) reference atomic environments are considered to construct the force field file. \(\alpha_t\) and \(l\) are the weight coefficients and length scale parameter of the non-linear regression model.

The method implements the recently proposed machine learning access to atomic forces as discussed extensively in the following publications - (Botu1) and (Botu2). The premise of the method is to map the atomic environment numerically into a fingerprint, and use machine learning methods to create a mapping to the vectorial atomic forces.

Only a single pair_coeff command is used with the `agni` style which specifies an AGNI potential file containing the parameters of the force field for the needed elements. These are mapped to LAMMPS atom types by specifying \(N\) additional arguments after the filename in the pair_coeff command, where \(N\) is the number of LAMMPS atom types:

- filename
- \(N\) element names = mapping of AGNI elements to atom types

See the `pair_coeff` page for alternate ways to specify the path for the force field file.

An AGNI force field is fully specified by the filename which contains the parameters of the force field, i.e., the reference training environments used to construct the machine learning force field. Example force field and input files are provided in the examples/PACKAGES/agni directory.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Accelerator packages`
The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

19.2.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

19.2.5 Restrictions

Currently, only elemental systems are implemented. Also, the method only provides access to the forces and not energies or stresses. The lack of potential energy data makes this pair style incompatible with several of the minimizer algorithms like cg or sd. It should work with damped dynamics based minimizers like fire or quickmin. However, one can access the energy via thermodynamic integration of the forces as discussed in (Botu3). This pair style is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

The AGNI force field files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the AGNI potential with any LAMMPS units, but you would need to create your own AGNI potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

pair_coeff * * ../potentials/CH.airebo-m H C

pair_style rebo
pair_coeff * * ../potentials/CH.rebo H C
```

19.5.3 Description

The `airebo` pair style computes the Adaptive Intermolecular Reactive Empirical Bond Order (AIREBO) Potential of (Stuart) for a system of carbon and/or hydrogen atoms. Note that this is the initial formulation of AIREBO from 2000, not the later formulation.

The `airebo/morse` pair style computes the AIREBO-M potential, which is equivalent to AIREBO, but replaces the LJ term with a Morse potential. The Morse potentials are parameterized by high-quality quantum chemistry (MP2) calculations and do not diverge as quickly as particle density increases. This allows AIREBO-M to retain accuracy to much higher pressures than AIREBO (up to 40 GPa for Polyethylene). Details for this potential and its parameterization are given in (O’Conner).
The *rebo* pair style computes the Reactive Empirical Bond Order (REBO) Potential of (Brenner). Note that this is the so-called second generation REBO from 2002, not the original REBO from 1990. As discussed below, second generation REBO is closely related to the initial AIREBO; it is just a subset of the potential energy terms with a few slightly different parameters.

The AIREBO potential consists of three terms:

\[
E = \frac{1}{2} \sum_i \sum_{j \neq i} \left( E_{REBO}^{ij} + E_{LJ}^{ij} + \sum_{k \neq i,j} \sum_{l \neq i,j,k} E_{TORSION}^{kijl} \right)
\]

By default, all three terms are included. For the *airebo* style, if the first two optional flag arguments to the pair_style command are included, the LJ and torsional terms can be turned off. Note that both or neither of the flags must be included. If both of the LJ and torsional terms are turned off, it becomes the second-generation REBO potential, with a small caveat on the spline fitting procedure mentioned below. This can be specified directly as pair_style rebo with no additional arguments.

The detailed formulas for this potential are given in (Stuart); here we provide only a brief description.

The \( E_{REBO} \) term has the same functional form as the hydrocarbon REBO potential developed in (Brenner). The coefficients for \( E_{REBO} \) in AIREBO are essentially the same as Brenner’s potential, but a few fitted spline values are slightly different. For most cases the \( E_{REBO} \) term in AIREBO will produce the same energies, forces and statistical averages as the original REBO potential from which it was derived. The \( E_{REBO} \) term in the AIREBO potential gives the model its reactive capabilities and only describes short-ranged C-C, C-H and H-H interactions (\( r < 2 \) Angstroms). These interactions have strong coordination-dependence through a bond order parameter, which adjusts the attraction between the I,J atoms based on the position of other nearby atoms and thus has 3- and 4-body dependence.

The \( E_{LJ} \) term adds longer-ranged interactions (2 < \( r < \) cutoff) using a form similar to the standard *Lennard Jones potential*. The \( E_{LJ} \) term in AIREBO contains a series of switching functions so that the short-ranged LJ repulsion (1/\( r^{12} \)) does not interfere with the energetics captured by the \( E_{REBO} \) term. The extent of the \( E_{LJ} \) interactions is determined by the cutoff argument to the pair_style command which is a scale factor. For each type pair (C-C, C-H, H-H) the cutoff is obtained by multiplying the scale factor by the sigma value defined in the potential file for that type pair. In the standard AIREBO potential, \( \sigma_{CC} = 3.4 \) Angstroms, so with a scale factor of 3.0 (the argument in pair_style), the resulting \( E_{LJ} \) cutoff would be 10.2 Angstroms.

By default, the longer-ranged interaction is smoothly switched off between 2.16 and 3.0 \( \sigma \). By specifying cutoff_min in addition to cutoff, the switching can be configured to take place between cutoff_min and cutoff. cutoff_min can only be specified if all optional arguments are given.

The \( E_{TORSION} \) term is an explicit 4-body potential that describes various dihedral angle preferences in hydrocarbon configurations.

Only a single pair_coeff command is used with the *airebo, airebo* or *rebo* style which specifies an AIREBO, REBO, or AIREBO-M potential file with parameters for C and H. Note that as of LAMMPS version 15 May 2019 the *rebo* style in LAMMPS uses its own potential file (CH.rebo). These are mapped to LAMMPS atom types by specifying \( N \) additional arguments after the filename in the pair_coeff command, where \( N \) is the number of LAMMPS atom types:

- filename
- \( N \) element names = mapping of AIREBO elements to atom types

See the *pair_coeff* page for alternate ways to specify the path for the potential file.

As an example, if your LAMMPS simulation has 4 atom types and you want the first 3 to be C, and the fourth to be H, you would use the following pair_coeff command:

```
pair_coeff * * CH.airebo C C C H
```
The first 2 arguments must be ** so as to span all LAMMPS atom types. The first three C arguments map LAMMPS atom types 1,2,3 to the C element in the AIREBO file. The final H argument maps LAMMPS atom type 4 to the H element in the SW file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when an airebo potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

The parameters/coefficients for the AIREBO potentials are listed in the CH.airebo file to agree with the original (Stuart) paper. Thus the parameters are specific to this potential and the way it was fit, so modifying the file should be done cautiously.

Similarly the parameters/coefficients for the AIREBO-M potentials are listed in the CH.airebo-m file to agree with the (O’Connor) paper. Thus the parameters are specific to this potential and the way it was fit, so modifying the file should be done cautiously. The AIREBO-M Morse potentials were parameterized using a cutoff of 3.0 (\(\sigma\)). Modifying this cutoff may impact simulation accuracy.

This pair style tallies a breakdown of the total AIREBO potential energy into sub-categories, which can be accessed via the *compute pair* command as a vector of values of length 3. The 3 values correspond to the following sub-categories:

1. \(E_{\text{REBO}}\) = REBO energy
2. \(E_{\text{LJ}}\) = Lennard-Jones energy
3. \(E_{\text{TORSION}}\) = Torsion energy

To print these quantities to the log file (with descriptive column headings) the following commands could be included in an input script:

```plaintext
compute 0 all pair airebo
variable REBO equal c_0[1]
variable LJ equal c_0[2]
variable TORSION equal c_0[3]
thermo_style custom step temp epair v_REBO v_LJ v_TORSION
```

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

### 19.5.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support the *pair_modify* mix, shift, table, and tail options.

These pair styles do not write their information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair style and pair_coeff commands in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.
19.5.5 Restrictions

These pair styles are part of the MANYBODY package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

These pair potentials require the newton setting to be “on” for pair interactions.

The CH.airebo and CH.airebo-m potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the AIREBO, AIREBO-M or REBO potential with any LAMMPS units, but you would need to create your own AIREBO or AIREBO-M potential file with coefficients listed in the appropriate units, if your simulation does not use “metal” units.

The pair styles provided here only support potential files parameterized for the elements carbon and hydrogen (designated with “C” and “H” in the pair_coeff command. Using potential files for other elements will trigger an error.

pair_coeff 1 1 atm 2 0.080
pair_coeff 1 2 atm 2 0.100
pair_coeff 2 2 atm 2 0.125
\end{verbatim}
19.6.3 Description

The `atm` style computes a 3-body Axilrod-Teller-Muto potential for the energy $E$ of a system of atoms as

$$E = \nu \frac{1 + 3 \cos \gamma_1 \cos \gamma_2 \cos \gamma_3}{r_{12}^3 r_{23}^3 r_{31}^3}$$

where $\nu$ is the three-body interaction strength. The distances between pairs of atoms $r_{12}$, $r_{23}$, $r_{31}$ and the angles $\gamma_1$, $\gamma_2$, $\gamma_3$ are as shown in this diagram:

![Diagram of a triangle with distances and angles labeled](image)

Note that for the interaction between a triplet of atoms $I$, $J$, $K$, there is no “central” atom. The interaction is symmetric with respect to permutation of the three atoms. Thus the $\nu$ value is the same for all those permutations of the atom types of $I$, $J$, $K$ and needs to be specified only once, as discussed below.

The `atm` potential is typically used in combination with a two-body potential using the `pair_style hybrid/overlay` command as in the example above.

The potential for a triplet of atom is calculated only if all 3 distances $r_{12}$, $r_{23}$, $r_{31}$ between the 3 atoms satisfy $r_{IJ} < \text{cutoff}$. In addition, the product of the 3 distances $r_{12} r_{23} r_{31} < \text{cutoff}_{\text{triple}}$ is required, which excludes from calculation the triplets with small contribution to the interaction.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the restart files read by the `read_restart` commands:

- $K =$ atom type of the third atom (1 to $N_{\text{types}}$)
- $\nu =$ prefactor (energy/distance$^9$ units)

$K$ can be specified in one of two ways. An explicit numeric value can be used, as in the second example above. $J \leq K$ is required. LAMMPS sets the coefficients for the other 5 symmetric interactions to the same values. E.g. if $I = 1$, $J = 2$, $K = 3$, then these 6 values are set to the specified $\nu$: $\nu_{123}$, $\nu_{132}$, $\nu_{213}$, $\nu_{231}$, $\nu_{312}$, $\nu_{321}$. This enforces the symmetry discussed above.

A wildcard asterisk can be used for $K$ to set the coefficients for multiple triplets of atom types. This takes the form “*” or “*n” or “n*” or “m*n”. If $N$ equals the number of atom types, then an asterisk with no numeric values means all types from 1 to $N$. A leading asterisk means all types from 1 to $n$ (inclusive). A trailing asterisk means all types from $n$ to $N$ (inclusive). A middle asterisk means all types from $m$ to $n$ (inclusive). Note that only type triplets with $J \leq K$ are considered; if asterisks imply type triplets where $K < J$, they are ignored.

Note that a `pair_coeff` command can override a previous setting for the same $I$, $J$, $K$ triplet. For example, these commands set $\nu$ for all $I$, $J$, $K$ triplets, then overwrite $\nu$ for just the $I$, $J$, $K = 2$, $3$, $4$ triplet:

```
pair_coeff  *  *  *  0.25  
pair_coeff  2 3 4 0.1
```

Note that for a simulation with a single atom type, only a single entry is required, e.g.

```
pair_coeff  1 1 1 0.25
```
For a simulation with two atom types, four pair_coeff commands will specify all possible nu values:

| pair_coeff | 1 1 1 nu1 |
| pair_coeff | 1 1 2 nu2 |
| pair_coeff | 1 2 2 nu3 |
| pair_coeff | 2 2 2 nu4 |

For a simulation with three atom types, ten pair_coeff commands will specify all possible nu values:

| pair_coeff | 1 1 1 nu1 |
| pair_coeff | 1 1 2 nu2 |
| pair_coeff | 1 1 3 nu3 |
| pair_coeff | 1 2 2 nu4 |
| pair_coeff | 1 2 3 nu5 |
| pair_coeff | 1 3 3 nu6 |
| pair_coeff | 2 2 2 nu7 |
| pair_coeff | 2 2 3 nu8 |
| pair_coeff | 2 3 3 nu9 |
| pair_coeff | 3 3 3 nu10 |

By default the $\nu$ value for all triplets is set to 0.0. Thus it is not required to provide pair_coeff commands that enumerate triplet interactions for all $K$ types. If some $I,J,K$ combination is not specified, then there will be no 3-body ATM interactions for that combination and all its permutations. However, as with all pair styles, it is required to specify a pair_coeff command for all $I,J$ combinations, else an error will result.

### 19.6.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style do not support the pair_modify mix, shift, table, and tail options.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file. However, if the atm potential is used in combination with other potentials using the pair_style hybrid/overlay command then pair_coeff commands need to be re-specified in the restart input script.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, and outer keywords.

### 19.6.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

19.7 pair_style awpmd/cut command

19.7.1 Syntax

```
pair_style awpmd/cut Rc keyword value ...
```

- Rc = global cutoff, -1 means cutoff of half the shortest box length
- zero or more keyword/value pairs may be appended
- keyword = hartree or dproduct or uhf or free or pbc or fix or harm or ermscale or flex_press
  - hartree value = none
  - dproduct value = none
  - uhf value = none
  - free value = none
  - pbc value = Plen
    - Plen = periodic width of electron = -1 or positive value (distance units)
  - fix value = Flen
    - Flen = fixed width of electron = -1 or positive value (distance units)
  - harm value = width
    - width = harmonic width constraint
  - ermscale value = factor
    - factor = scaling between electron mass and width variable mass
  - flex_press value = none

19.7.2 Examples

```
pair_style awpmd/cut -1
pair_style awpmd/cut 40.0 uhf free
pair_coeff * *
pair_coeff 2 2 20.0
```
19.7.3 Description

This pair style contains an implementation of the Antisymmetrized Wave Packet Molecular Dynamics (AWPMD) method. Need citation here. Need basic formulas here. Could be links to other documents.

Rc is the cutoff.

The pair_style command allows for several optional keywords to be specified.

The *hartree*, *dproduct*, and *uhf* keywords specify the form of the initial trial wave function for the system. If the *hartree* keyword is used, then a Hartree multielectron trial wave function is used. If the *dproduct* keyword is used, then a trial function which is a product of two determinants for each spin type is used. If the *uhf* keyword is used, then an unrestricted Hartree-Fock trial wave function is used.

The *free*, *pbc*, and *fix* keywords specify a width constraint on the electron wave packets. If the *free* keyword is specified, then there is no constraint. If the *pbc* keyword is used and *Plen* is specified as -1, then the maximum width is half the shortest box length. If *Plen* is a positive value, then the value is the maximum width. If the *fix* keyword is used and *Flen* is specified as -1, then electrons have a constant width that is read from the data file. If *Flen* is a positive value, then the constant width for all electrons is set to *Flen*.

The *harm* keyword allow oscillations in the width of the electron wave packets. More details are needed.

The *ermscale* keyword specifies a unitless scaling factor between the electron masses and the width variable mass. More details needed.

If the *flex_press* keyword is used, then a contribution from the electrons is added to the total virial and pressure of the system.

This potential is designed to be used with *atom_style wavepacket* definitions, in order to handle the description of systems with interacting nuclei and explicit electrons.

The following coefficients must be defined for each pair of atom types via the *pair_coeff* command as in the examples above, or in the data file or restart files read by the *read_data* or *read_restart* commands, or by mixing as described below:

• cutoff (distance units)

For *awpmd/cut*, the cutoff coefficient is optional. If it is not used (as in some of the examples above), the default global value specified in the pair_style command is used.

19.7.4 Mixing, shift, table, tail correction, restart, rRESPA info

The *pair_modify* mix, shift, table, and tail options are not relevant for this pair style.

This pair style writes its information to *binary restart files*, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run_style respa* command. It does not support the *inner*, *middle*, *outer* keywords.

Accelerator Variants: beck/gpu, beck/omp

19.8.1 Syntax

```cpp
pair_style beck Rc
```

- Rc = cutoff for interactions (distance units)

19.8.2 Examples

```cpp
pair_style beck 8.0
pair_coeff * * 399.671876712 0.0000867636112694 0.675 4.390 0.0003746
pair_coeff 1 1 399.671876712 0.0000867636112694 0.675 4.390 0.0003746 6.0
```

19.8.3 Description

Style beck computes interactions based on the potential by (Beck), originally designed for simulation of Helium. It includes truncation at a cutoff distance Rc.

\[
E(r) = A \exp \left[ -\alpha r - \beta r^6 \right] - \frac{B}{(r^2 + a^2)^3} \left( 1 + \frac{2.709 + 3a^2}{r^2 + a^2} \right) \quad r < R_c
\]

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands.

- A (energy units)
- B (energy-distance^6 units)
- a (distance units)
- \alpha (1/distance units)
- \beta (1/distance^6 units)
- cutoff (distance units)
The last coefficient is optional. If not specified, the global cutoff $R_c$ is used.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script. See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 19.8.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, coefficients must be specified. No default mixing rules are used.

This pair style does not support the `pair_modify` shift option for the energy of the pair interaction.

The `pair_modify` table option is not relevant for this pair style.

This pair style does not support the `pair_modify` tail option for adding long-range tail corrections.

This pair style writes its information to binary restart files, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

### 19.8.5 Restrictions

19.9 pair_style body/nparticle command

19.9.1 Syntax

```
pair_style body/nparticle cutoff
```
cutoff = global cutoff for interactions (distance units)

19.9.2 Examples

```
pair_style body/nparticle 3.0
pair_coeff *= 1.0 1.0
pair_coeff 1 1 1.0 1.5 2.5
```

19.9.3 Description

Style `body/nparticle` is for use with body particles and calculates pairwise body/body interactions as well as interactions between body and point-particles. See the Howto body doc page for more details on using body particles.

This pair style is designed for use with the “nparticle” body style, which is specified as an argument to the “atom-style body” command. See the Howto body page for more details about the body styles LAMMPS supports. The “nparticle” style treats a body particle as a rigid body composed of N sub-particles.

The coordinates of a body particle are its center-of-mass (COM). If the COMs of a pair of body particles are within the cutoff (global or type-specific, as specified above), then all interactions between pairs of sub-particles in the two body particles are computed. E.g. if the first body particle has 3 sub-particles, and the second has 10, then 30 interactions are computed and summed to yield the total force and torque on each body particle.

**Note:** In the example just described, all 30 interactions are computed even if the distance between a particular pair of sub-particles is greater than the cutoff. Likewise, no interaction between two body particles is computed if the two COMs are further apart than the cutoff, even if the distance between some pairs of their sub-particles is within the cutoff. Thus care should be used in defining the cutoff distances for body particles, depending on their shape and size.

Similar rules apply for a body particle interacting with a point particle. The distance between the two particles is calculated using the COM of the body particle and the position of the point particle. If the distance is within the cutoff and the body particle has N sub-particles, then N interactions with the point particle are computed and summed. If the distance is not within the cutoff, no interactions between the body and point particle are computed.

The interaction between two sub-particles, or a sub-particle and point particle, or between two point particles is computed as a Lennard-Jones interaction, using the standard formula

\[ E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right] \quad r < R_c \]

where \( R_c \) is the cutoff. As explained above, an interaction involving one or two body sub-particles may be computed even for \( r > R_c \).

For style `body`, the following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)
• cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff is used.

---

19.9.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distance for all of this pair style can be mixed. The default mix value is geometric. See the pair_modify command for details.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

---

19.9.5 Restrictions

This style is part of the BODY package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

Defining particles to be bodies so they participate in body/body or body/particle interactions requires the use of the atom_style body command.

---

19.9.6 Related commands

pair_coeff, fix rigid

19.10 pair_style body/rounded/polygon command

19.10.1 Syntax

```
pair_style body/rounded/polygon c_n c_t mu delta_ua cutoff
```

c_n = normal damping coefficient
c_t = tangential damping coefficient
mu = normal friction coefficient during gross sliding
delta_ua = multiple contact scaling factor
cutoff = global separation cutoff for interactions (distance units), see below for definition
19.10.2 Examples

```
pair_style body/rounded/polygon 20.0 5.0 0.0 1.0 0.5
pair_coeff * * 100.0 1.0
pair_coeff 1 1 100.0 1.0
```

19.10.3 Description

Style `body/rounded/polygon` is for use with 2d models of body particles of style `rounded/polygon`. It calculates pairwise body/body interactions which can include body particles modeled as 1-vertex circular disks with a specified diameter. See the `Howto body` page for more details on using body rounded/polygon particles.

This pairwise interaction between rounded polygons is described in *Fraige*, where a polygon does not have sharp corners, but is rounded at its vertices by circles centered on each vertex with a specified diameter. The edges of the polygon are defined between pairs of adjacent vertices. The circle diameter for each polygon is specified in the data file read by the `read data` command. This is a 2d discrete element model (DEM) which allows for multiple contact points.

Note that when two particles interact, the effective surface of each polygon particle is displaced outward from each of its vertices and edges by half its circle diameter (as in the diagram below of a gray and yellow square particle). The interaction forces and energies between two particles are defined with respect to the separation of their respective rounded surfaces, not by the separation of the vertices and edges themselves.

This means that the specified cutoff in the `pair_style` command is the cutoff distance, $r_c$, for the surface separation, $\delta_n$ (see figure below). This is the distance at which two particles no longer interact. If $r_c$ is specified as 0.0, then it is a contact-only interaction. I.e. the two particles must overlap in order to exert a repulsive force on each other. If $r_c > 0.0$, then the force between two particles will be attractive for surface separations from 0 to $r_c$, and repulsive once the particles overlap.

Note that unlike for other pair styles, the specified cutoff is not the distance between the centers of two particles at which they stop interacting. This center-to-center distance depends on the shape and size of the two particles and their relative orientation. LAMMPS takes that into account when computing the surface separation distance and applying the $r_c$ cutoff.

The forces between vertex-vertex, vertex-edge, and edge-edge overlaps are given by:

$$ F_n = \begin{cases} k_n \delta_n - c_n \delta_n v_n & \delta_n \leq 0 \\ -k_n a \delta_n - c_n \delta_n v_n & 0 < \delta_n \leq r_c \\ 0 & \delta_n > r_c \end{cases} $$

$$ F_t = \begin{cases} \mu k_n \delta_n - c_t v_t & \delta_n \leq 0 \\ 0 & \delta_n > 0 \end{cases} $$
Note that $F_n$ and $F_t$ are functions of the surface separation $\delta_n = d - (R_i + R_j)$. In this model, when $(R_i + R_j) < d < (R_i + R_j) + r_c$, that is, $0 < \delta_n < r_c$, the cohesive region of the two surfaces overlap and the two surfaces are attractive to each other.

In *Fraige*, the tangential friction force between two particles that are in contact is modeled differently prior to gross sliding (i.e. static friction) and during gross-sliding (kinetic friction). The latter takes place when the tangential deformation exceeds the Coulomb frictional limit. In the current implementation, however, we do not take into account frictional history, i.e. we do not keep track of how many time steps the two particles have been in contact nor calculate the tangential deformation. Instead, we assume that gross sliding takes place as soon as two particles are in contact.

The following coefficients must be defined for each pair of atom types via the *pair_coeff* command as in the examples above, or in the data file read by the *read_data* command:

- $k_n$ (energy/distance$^2$ units)
- $k_{na}$ (energy/distance$^2$ units)
Effectively, \( k_n \) and \( k_{na} \) are the slopes of the red lines in the plot above for force versus surface separation, for \( \delta_n < 0 \) and \( 0 < \delta_n < r_c \) respectively.

### 19.10.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the `pair_modify` mix, shift, table, and tail options.

This pair style does not write its information to binary restart files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

### 19.10.5 Restrictions

These pair styles are part of the BODY package. They are only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

This pair style requires the `newton` setting to be “on” for pair interactions.

### 19.10.6 Related commands

### 19.10.7 Default

none

### 19.11 pair_style body/rounded/polyhedron command

#### 19.11.1 Syntax

```
pair_style body/rounded/polyhedron c_n c_t mu delta ua cutoff
```

- \( c_n \) = normal damping coefficient
- \( c_t \) = tangential damping coefficient
- \( mu \) = normal friction coefficient during gross sliding
- \( delta \) = multiple contact scaling factor
- \( cutoff \) = global separation cutoff for interactions (distance units), see below for explanation
19.11.2 Examples

```
pair_style body/rounded/polyhedron 20.0 5.0 0.0 1.0 0.5
pair_coeff * * 100.0 1.0
pair_coeff 1 1 100.0 1.0
```

19.11.3 Description

Style `body/rounded/polygon` is for use with 3d models of body particles of style `rounded/polyhedron`. It calculates pairwise body/body interactions which can include body particles modeled as 1-vertex spheres with a specified diameter. See the *Howto body* page for more details on using body rounded/polyhedron particles.

This pairwise interaction between the rounded polyhedra is described in *Wang*, where a polyhedron does not have sharp corners and edges, but is rounded at its vertices and edges by spheres centered on each vertex with a specified diameter. The edges if the polyhedron are defined between pairs of adjacent vertices. Its faces are defined by a loop of edges. The sphere diameter for each polygon is specified in the data file read by the *read data* command. This is a discrete element model (DEM) which allows for multiple contact points.

Note that when two particles interact, the effective surface of each polyhedron particle is displaced outward from each of its vertices, edges, and faces by half its sphere diameter. The interaction forces and energies between two particles are defined with respect to the separation of their respective rounded surfaces, not by the separation of the vertices, edges, and faces themselves.

This means that the specified cutoff in the pair_style command is the cutoff distance, $r_c$, for the surface separation, $\delta_n$ (see figure below). This is the distance at which two particles no longer interact. If $r_c$ is specified as 0.0, then it is a contact-only interaction. I.e. the two particles must overlap in order to exert a repulsive force on each other. If $r_c > 0.0$, then the force between two particles will be attractive for surface separations from 0 to $r_c$, and repulsive once the particles overlap.

Note that unlike for other pair styles, the specified cutoff is not the distance between the centers of two particles at which they stop interacting. This center-to-center distance depends on the shape and size of the two particles and their relative orientation. LAMMPS takes that into account when computing the surface separation distance and applying the $r_c$ cutoff.

The forces between vertex-vertex, vertex-edge, vertex-face, edge-edge, and edge-face overlaps are given by:

$$
F_n = \begin{cases} 
k_n\delta_n - c_nv_n, & \delta_n \leq 0 \\
-k_{na}\delta_n - c_nv_n, & 0 < \delta_n \leq r_c \\
0, & \delta_n > r_c
\end{cases}
$$

$$
F_t = \begin{cases} 
\mu k_n\delta_n - c_tv_t, & \delta_n \leq 0 \\
0, & \delta_n > 0
\end{cases}
$$
In Wang, the tangential friction force between two particles that are in contact is modeled differently prior to gross sliding (i.e. static friction) and during gross-sliding (kinetic friction). The latter takes place when the tangential deformation exceeds the Coulomb frictional limit. In the current implementation, however, we do not take into account frictional history, i.e. we do not keep track of how many time steps the two particles have been in contact nor calculate the tangential deformation. Instead, we assume that gross sliding takes place as soon as two particles are in contact.

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above, or in the data file read by the `read_data` command:

- $k_n$ (energy/distance$^2$ units)
- $k_{na}$ (energy/distance$^2$ units)

Effectively, $k_n$ and $k_{na}$ are the slopes of the red lines in the plot above for force versus surface separation, for $\delta_n < 0$ and $0 < \delta_n < r_c$ respectively.
19.11.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the `pair_modify` mix, shift, table, and tail options. This pair style does not write its information to binary restart files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file. This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

19.11.5 Restrictions

These pair styles are part of the BODY package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info. This pair style requires the `newton` setting to be “on” for pair interactions.

```
19.12.3 Description

The *bop* pair style computes Bond-Order Potentials (BOP) based on quantum mechanical theory incorporating both \( \sigma \) and \( \pi \) bonding. By analytically deriving the BOP from quantum mechanical theory its transferability to different phases can approach that of quantum mechanical methods. This potential is similar to the original BOP developed by Pettifor (Pettifor_1, Pettifor_2, Pettifor_3) and later updated by Murdick, Zhou, and Ward (Murdick, Ward). Currently, BOP potential files for these systems are provided with LAMMPS: AlCu, CCu, CdTe, CdTeSe, CdZnTe, CuH, GaAs. A system with only a subset of these elements, including a single element (e.g. C or Cu or Al or Ga or Zn or CdZn), can also be modeled by using the appropriate alloy file and assigning all atom types to the single element or subset of elements via the *pair_coeff* command, as discussed below.

The BOP potential consists of three terms:

\[
E = \frac{1}{2} \sum_{i=1}^{N} \sum_{j=i+1}^{N} \phi_{ij} (r_{ij}) - \sum_{i=1}^{N} \sum_{j=i+1}^{N} \beta_{\sigma,ij} (r_{ij}) \cdot \Theta_{\sigma,ij} - \sum_{i=1}^{N} \sum_{j=i+1}^{N} \beta_{\pi,ij} (r_{ij}) \cdot \Theta_{\pi,ij} + U_{prom}
\]

where \( \phi_{ij} (r_{ij}) \) is a short-range two-body function representing the repulsion between a pair of ion cores, \( \beta_{\sigma,ij} (r_{ij}) \) and \( \beta_{\pi,ij} (r_{ij}) \) are respectively sigma and \( \pi \) bond integrals, \( \Theta_{\sigma,ij} \) and \( \Theta_{\pi,ij} \) are \( \sigma \) and \( \pi \) bond-orders, and \( U_{prom} \) is the promotion energy for sp-valent systems.

The detailed formulas for this potential are given in Ward (Ward); here we provide only a brief description.

The repulsive energy \( \phi_{ij} (r_{ij}) \) and the bond integrals \( \beta_{\sigma,ij} (r_{ij}) \) and \( \beta_{\phi,ij} (r_{ij}) \) are functions of the interatomic distance \( r_{ij} \) between atom \( i \) and \( j \). Each of these potentials has a smooth cutoff at a radius of \( r_{cut,ij} \). These smooth cutoffs ensure stable behavior at situations with high sampling near the cutoff such as melts and surfaces.

The bond-orders can be viewed as environment-dependent local variables that are \( ij \) bond specific. The maximum value of the \( \sigma \) bond-order (\( \Theta_{\sigma} \)) is 1, while that of the \( \pi \) bond-order (\( \Theta_{\pi} \)) is 2, attributing to a maximum value of the total bond-order (\( \Theta_{\sigma} + \Theta_{\pi} \)) of 3. The \( \sigma \) and \( \pi \) bond-orders reflect the ubiquitous single-, double-, and triple- bond behavior of chemistry. Their analytical expressions can be derived from tight-binding theory by recursively expanding an inter-site Green’s function as a continued fraction. To accurately represent the bonding with a computationally efficient potential formulation suitable for MD simulations, the derived BOP only takes (and retains) the first two levels of the recursive representations for both the \( \sigma \) and the \( \pi \) bond-orders. Bond-order terms can be understood in terms of molecular orbital hopping paths based upon the Cyrot-Lackmann theorem (Pettifor_I). The \( \sigma \) bond-order with a half-full valence shell is used to interpolate the bond-order expression that incorporated explicit valance band filling. This \( \pi \) bond-order expression also contains also contains a three-member ring term that allows implementation of an asymmetric density of states, which helps to either stabilize or destabilize close-packed structures. The \( \pi \) bond-order includes hopping paths of length 4. This enables the incorporation of dihedral angles effects.

**Note:** Note that unlike for other potentials, cutoffs for BOP potentials are not set in the *pair_style* or *pair_coeff* command; they are specified in the BOP potential files themselves. Likewise, the BOP potential files list atomic masses; thus you do not need to use the *mass* command to specify them. Note that for BOP potentials with hydrogen, you will likely want to set the mass of H atoms to be 10x or 20x larger to avoid having to use a tiny timestep. You can do this by using the *mass* command after using the *pair_coeff* command to read the BOP potential file.

One option can be specified as a keyword with the *pair_style* command.

The *save* keyword gives you the option to calculate in advance and store a set of distances, angles, and derivatives of angles. The default is to not do this, but to calculate them on-the-fly each time they are needed. The former may be faster, but takes more memory. The latter requires less memory, but may be slower. It is best to test this option to optimize the speed of BOP for your particular system configuration.

Only a single *pair_coeff* command is used with the *bop* style which specifies a BOP potential file, with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the *pair_coeff* command, where N is the number of LAMMPS atom types:
• filename
• N element names = mapping of BOP elements to atom types

As an example, imagine the CdTe.bop file has BOP values for Cd and Te. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Cd, and the fourth to be Te, you would use the following pair_coeff command:

```
pair_coeff * * CdTe Cd Cd Cd Te
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first three Cd arguments map LAMMPS atom types 1,2,3 to the Cd element in the BOP file. The final Te argument maps LAMMPS atom type 4 to the Te element in the BOP file.

BOP files in the potentials directory of the LAMMPS distribution have a “.bop” suffix. The potentials are in tabulated form containing pre-tabulated pair functions for phi_ij(r_ij), beta_(sigma,ij)(r_ij), and beta_pi,ij)(r_ij).

The parameters/coefficients format for the different kinds of BOP files are given below with variables matching the formulation of Ward (Ward) and Zhou (Zhou). Each header line containing a “;” is preceded by a blank line.

---

No angular table file format:

The parameters/coefficients format for the BOP potentials input file containing pre-tabulated functions of g is given below with variables matching the formulation of Ward (Ward). This format also assumes the angular functions have the formulation of (Ward).

- Line 1: # elements N

The first line is followed by N lines containing the atomic number, mass, and element symbol of each element.

Following the definition of the elements several global variables for the tabulated functions are given.

- Line 1: nr, nBOt (nr is the number of divisions the radius is broken into for function tables and MUST be a factor of 5; nBOt is the number of divisions for the tabulated values of THETA_(S,ij)
- Line 2: delta_1-delta_7 (if all are not used in the particular formulation, set unused values to 0.0)

Following this N lines for e_1-e_N containing p_pi.

- Line 3: p_pi (for e_1)
- Line 4: p_pi (for e_2 and continues to e_N)

The next section contains several pair constants for the number of interaction types e_i-e_j, with i=1->N, j=i->N

- Line 1: r_cut (for e_1-e_1 interactions)
- Line 2: c_sigma, a_sigma, c_pi, a_pi
- Line 3: delta_sigma, delta_pi
- Line 4: f_sigma, k_sigma, delta_3 (This delta_3 is similar to that of the previous section but is interaction type dependent)

The next section contains a line for each three body interaction type e_j-e_i-e_k with i=0->N, j=0->N, k=j->N

- Line 1: g_(sigma0), g_(sigma1), g_(sigma2) (These are coefficients for g_(sigma,ijk)(THETA_ijk) for e_1-e_1-e_1 interaction. Ward contains the full expressions for the constants as functions of b_(sigma,ijk), p_(sigma,ijk), u_(sigma,ijk))
- Line 2: g_(sigma0), g_(sigma1), g_(sigma2) (for e_1-e_1-e_2)

The next section contains a block for each interaction type for the phi_ij(r_ij). Each block has nr entries with 5 entries per line.

---

19.12. pair_style bop command
• Line 1: \(\phi(r_1), \phi(r_2), \phi(r_3), \phi(r_4), \phi(r_5)\) (for the \(e_1-e_1\) interaction type)

• Line \(nr/5\_1\): \(\phi(r_1), \phi(r_2), \phi(r_3), \phi(r_4), \phi(r_5)\), (for the \(e_1-e_1\) interaction type)

The next section contains a block for each interaction type for the \(\beta_{\sigma,ij}(r_{ij})\). Each block has \(nr\) entries with 5 entries per line.
• Line 1: \(\beta_{\sigma}(r_1), \beta_{\sigma}(r_2), \beta_{\sigma}(r_3), \beta_{\sigma}(r_4), \beta_{\sigma}(r_5)\) (for the \(e_1-e_1\) interaction type)
• Line 2: \(\beta_{\sigma}(r_6), \beta_{\sigma}(r_7), \beta_{\sigma}(r_8), \beta_{\sigma}(r_9), \beta_{\sigma}(r_{10})\) (this continues until \(nr\))
• …
• Line \(nr/5+1\): \(\beta_{\sigma}(r_1), \beta_{\sigma}(r_2), \beta_{\sigma}(r_3), \beta_{\sigma}(r_4), \beta_{\sigma}(r_5)\) (for the \(e_1-e_2\) interaction type)

The next section contains a block for each interaction type for \(\beta_{\pi,ij}(r_{ij})\). Each block has \(nr\) entries with 5 entries per line.
• Line 1: \(\beta_{\pi}(r_1), \beta_{\pi}(r_2), \beta_{\pi}(r_3), \beta_{\pi}(r_4), \beta_{\pi}(r_5)\) (for the \(e_1-e_1\) interaction type)
• Line 2: \(\beta_{\pi}(r_6), \beta_{\pi}(r_7), \beta_{\pi}(r_8), \beta_{\pi}(r_9), \beta_{\pi}(r_{10})\) (this continues until \(nr\))
• …
• Line \(nr/5+1\): \(\beta_{\pi}(r_1), \beta_{\pi}(r_2), \beta_{\pi}(r_3), \beta_{\pi}(r_4), \beta_{\pi}(r_5)\) (for the \(e_1-e_2\) interaction type)

The next section contains a block for each interaction type for \(\Theta_{S,ij}((\Theta_{\sigma,ij})^{1/2}, f_{\sigma,ij})\). Each block has \(nBoT\) entries with 5 entries per line.
• Line 1: \(\Theta_{S,ij}(r_1), \Theta_{S,ij}(r_2), \Theta_{S,ij}(r_3), \Theta_{S,ij}(r_4), \Theta_{S,ij}(r_5)\) (for the \(e_1-e_2\) interaction type)
• Line 2: \(\Theta_{S,ij}(r_6), \Theta_{S,ij}(r_7), \Theta_{S,ij}(r_8), \Theta_{S,ij}(r_9), \Theta_{S,ij}(r_{10})\) (this continues until \(nBoT\))
• …
• Line \(nBoT/5+1\): \(\Theta_{S,ij}(r_1), \Theta_{S,ij}(r_2), \Theta_{S,ij}(r_3), \Theta_{S,ij}(r_4), \Theta_{S,ij}(r_5)\) (for the \(e_1-e_2\) interaction type)

The next section contains a block of \(N\) lines for \(e_1-e_N\)
• Line 1: \(\delta^{\mu} (\text{for } e_1)\)
• Line 2: \(\delta^{\mu} (\text{for } e_2 \text{ and repeats to } e_N)\)

The last section contains more constants for \(e_i-e_j\) interactions with \(i=0->N, j=i->N\)
• Line 1: \((A_{ij})^{\mu*nu} (\text{for } e1-e1)\)
• Line 2: \((A_{ij})^{\mu*nu} (\text{for } e1-e2 \text{ and repeats as above})\)

Angular spline table file format:
The parameters/coefficients format for the BOP potentials input file containing pre-tabulated functions of \(g\) is given below with variables matching the formulation of Ward (Ward). This format also assumes the angular functions have the formulation of (Zhou).
• Line 1: \# elements \(N\)
The first line is followed by N lines containing the atomic number, mass, and element symbol of each element.

Following the definition of the elements several global variables for the tabulated functions are given.

- Line 1: nr, ntheta, nBOt (nr is the number of divisions the radius is broken into for function tables and MUST be a factor of 5; ntheta is the number of divisions for the tabulated values of the power of the spline used to fit the angular function; nBOt is the number of divisions for the tabulated values of THETA_(S,ij)
- Line 2: delta_1-delta_7 (if all are not used in the particular formulation, set unused values to 0.0)

Following this N lines for e_1-e_N containing p_pi.

- Line 3: p_pi (for e_1)
- Line 4: p_pi (for e_2 and continues to e_N)

The next section contains several pair constants for the number of interaction types e_i-e_j, with i=1->N, j=i->N

- Line 1: r_cut (for e_1-e_1 interactions)
- Line 2: c_sigma, a_sigma, c_pi, a_pi
- Line 3: delta_sigma, delta_pi
- Line 4: f_sigma, k_sigma, delta_3 (This delta_3 is similar to that of the previous section but is interaction type dependent)

The next section contains a line for each three body interaction type e_j-e_i-e_k with i=0->N, j=0->N, k=j->N

- Line 1: g0, g1, g2… (These are coefficients for the angular spline of the g_(sigma,jik)(THETA_ijk) for e_1-e_1-e_1 interaction. The function can contain up to 10 term thus 10 constants. The first line can contain up to five constants. If the spline has more than five terms the second line will contain the remaining constants The following lines will then contain the constants for the remaining g0, g1, g2… (for e_1-e_1-e_2) and the other three body interactions

The rest of the table has the same structure as the previous section (see above).

Angular no-spline table file format:

The parameters/coefficients format for the BOP potentials input file containing pre-tabulated functions of g is given below with variables matching the formulation of Ward (Ward). This format also assumes the angular functions have the formulation of (Zhou).

- Line 1: # elements N

The first two lines are followed by N lines containing the atomic number, mass, and element symbol of each element.

Following the definition of the elements several global variables for the tabulated functions are given.

- Line 1: nr, ntheta, nBOt (nr is the number of divisions the radius is broken into for function tables and MUST be a factor of 5; ntheta is the number of divisions for the tabulated values of the g angular function; nBOt is the number of divisions for the tabulated values of THETA_(S,ij)
- Line 2: delta_1-delta_7 (if all are not used in the particular formulation, set unused values to 0.0)

Following this N lines for e_1-e_N containing p_pi.

- Line 3: p_pi (for e_1)
- Line 4: p_pi (for e_2 and continues to e_N)

The next section contains several pair constants for the number of interaction types e_i-e_j, with i=1->N, j=i->N
• Line 1: r_cut (for e_1-e_1 interactions)
• Line 2: c_sigma, a_sigma, c_pi, a_pi
• Line 3: delta_sigma, delta_pi
• Line 4: f_sigma, k_sigma, delta_3 (This delta_3 is similar to that of the previous section but is interaction type dependent)

The next section contains a line for each three body interaction type e_j-e_i-e_k with i=0->N, j=0->N, k=j->N
• Line 1: g(theta1), g(theta2), g(theta3), g(theta4), g(theta5) (for the e_1-e_1-e_1 interaction type)
• Line 2: g(theta6), g(theta7), g(theta8), g(theta9), g(theta10) (this continues until ntheta)
• …
• Line ntheta/5+1: g(theta1), g(theta2), g(theta3), g(theta4), g(theta5), (for the e_1-e_1-e_2 interaction type)

The rest of the table has the same structure as the previous section (see above).

19.12.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair_modify mix, shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

19.12.5 Restrictions

These pair styles are part of the MANYBODY package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

These pair potentials require the newton setting to be “on” for pair interactions.

Pair style bop is not compatible with being used as a sub-style with doc:hybrid pair styles <pair_hybrid>. Pair style bop is also not compatible with multi-cutoff neighbor lists or multi-cutoff communication.

The .bop.table potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the BOP potential with any LAMMPS units, but you would need to create your own BOP potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

```
19.17.3 Description

The *born* style computes the Born-Mayer-Huggins or Tosi/Fumi potential described in *(Fumi and Tosi)*, given by

\[
E = A \exp \left( \frac{\sigma - r}{\rho} \right) - \frac{C}{r^6} + \frac{D}{r^8} \quad r < r_c
\]

where \(\sigma\) is an interaction-dependent length parameter, \(\rho\) is an ionic-pair dependent length parameter, and \(r_c\) is the cutoff.

The styles with *coul/long* or *coul/msm* add a Coulombic term as described for the *lj/cut* pair styles. An additional damping factor is applied to the Coulombic term so it can be used in conjunction with the *kspace_style* command and its *ewald* or *pppm* of *msm* option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

If one cutoff is specified for the *born/coul/long* and *born/coul/msm* style, it is used for both the A,C,D and Coulombic terms. If two cutoffs are specified, the first is used as the cutoff for the A,C,D terms, and the second is the cutoff for the Coulombic term.

The *born/coul/wolf* style adds a Coulombic term as described for the Wolf potential in the *coul/wolf* pair style.

The *born/coul/dsf* style computes the Coulomb contribution with the damped shifted force model as in the *coul/dsf* style.

Note that these potentials are related to the *Buckingham potential*.

The following coefficients must be defined for each pair of atoms types via the *pair_coeff* command as in the examples above, or in the data file or restart files read by the *read_data* or *read_restart* commands, or by mixing as described below:

- A (energy units)
- \(\rho\) (distance units)
- \(\sigma\) (distance units)
- C (energy units * distance units^6)
- D (energy units * distance units^8)
- cutoff (distance units)

The second coefficient, rho, must be greater than zero. The last coefficient is optional. If not specified, the global A,C,D cutoff specified in the *pair_style* command is used.

For *born/coul/long*, *born/coul/wolf* and *born/coul/dsf* no Coulombic cutoff can be specified for an individual LJ type pair. All type pairs use the same global Coulombic cutoff specified in the *pair_style* command.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.
19.17.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

These styles support the `pair_modify` shift option for the energy of the exp(), 1/r^6, and 1/r^8 portion of the pair interaction.

The `born/coul/long` pair style supports the `pair_modify` table option to tabulate the short-range portion of the long-range Coulombic interaction.

These styles support the `pair_modify` tail option for adding long-range tail corrections to energy and pressure.

These styles writes thei information to binary `restart` files, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

These styles can only be used via the `pair` keyword of the `run_style respa` command. They do not support the `inner`, `middle`, `outer` keywords.

19.17.5 Restrictions

The `born/coul/long` style is part of the KSPACE package. It is only enabled if LAMMPS was built with that package. See the `Build package` page for more info.

The `born/coul/dsf` and `born/coul/wolf` pair styles are part of the EXTRA-PAIR package. They are only enabled if LAMMPS was built with that package. See the `Build package` page for more info.

19.18 pair_style bpm/spring command

19.18.1 Syntax

```
pair_style bpm/spring
```
19.18.2 Examples

```plaintext
pair_style bpm/spring
pair_coeff * * 1.0 1.0 1.0
pair_coeff 1 1 1.0 1.0 1.0
```

19.18.3 Description

Style `bpm/spring` computes pairwise forces with the formula

\[ F = k(r - r_c) \]

where \( k \) is a stiffness and \( r_c \) is the cutoff length. An additional damping force is also applied to interacting particles. The force is proportional to the difference in the normal velocity of particles

\[ F_D = -\gamma w(\hat{r} \cdot \vec{v}) \]

where \( \gamma \) is the damping strength, \( \hat{r} \) is the radial normal vector, \( \vec{v} \) is the velocity difference between the two particles, and \( w \) is a smoothing factor. This smoothing factor is constructed such that damping forces go to zero as particles come out of contact to avoid discontinuities. It is given by

\[ w = 1.0 - \left( \frac{r}{r_c} \right)^8. \]

This pair style is designed for use in a spring-based bonded particle model. It mirrors the construction of the `bpm/spring` bond style.

This pair interaction is always applied to pairs of non-bonded particles that are within the interaction distance. For pairs of bonded particles that are within the interaction distance, there is the option to either include this pair interaction and overlay the pair force over the bond force or to exclude this pair interaction such that the two particles only interact via the bond force. See discussion of the `overlay/pair` option for BPM bond styles and the `special_bonds` command in the :doc: how to <Howto_BPM> page on BPMs for more details.

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- \( k \) (force/distance units)
- \( r_c \) (distance units)
- \( \gamma \) (force/velocity units)

19.18.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the A coefficient and cutoff distance for this pair style can be mixed. A is always mixed via a geometric rule. The cutoff is mixed according to the `pair_modify` mix value. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the `pair_modify` shift option, since the pair interaction goes to 0.0 at the cutoff.

The `pair_modify` table and tail options are not relevant for this pair style.

This pair style writes its information to binary restart files, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.
This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

Accelerator Variants: brownian/poly/omp

19.20.1 Syntax

```
pair_style style mu flaglog flagfld cutinner cutoff t_target seed flagHI flagVF
```

- style = brownian or brownian/poly
- mu = dynamic viscosity (dynamic viscosity units)
- flaglog = 0/1 log terms in the lubrication approximation on/off
- flagfld = 0/1 to include/exclude Fast Lubrication Dynamics effects
- cutinner = inner cutoff distance (distance units)
- cutoff = outer cutoff for interactions (distance units)
- t_target = target temp of the system (temperature units)
- seed = seed for the random number generator (positive integer)
- flagHI (optional) = 0/1 to include/exclude 1/r hydrodynamic interactions
- flagVF (optional) = 0/1 to include/exclude volume fraction corrections in the long-range isotropic terms
19.20.2 Examples

```
pair_style brownian 1.5 1 2.01 2.5 2.0 5878567 (assuming radius = 1)
pair_coeff 1 1 2.05 2.8
pair_coeff * *
```

19.20.3 Description

Styles `brownian` and `brownian/poly` compute Brownian forces and torques on finite-size spherical particles. The former requires monodisperse spherical particles; the latter allows for polydisperse spherical particles.

These pair styles are designed to be used with either the `pair_style lubricate` or `pair_style lubricateU` commands to provide thermostatting when dissipative lubrication forces are acting. Thus the parameters `mu`, `flaglog`, `flagfld`, `cutinner`, and `cutoff` should be specified consistent with the settings in the lubrication pair styles. For details, refer to either of the lubrication pair styles.

The `t_target` setting is used to specify the target temperature of the system. The random number `seed` is used to generate random numbers for the thermostatting procedure.

The `flagHI` and `flagVF` settings are optional. Neither should be used, or both must be defined.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- `cutinner` (distance units)
- `cutoff` (distance units)

The two coefficients are optional. If neither is specified, the two cutoffs specified in the pair_style command are used. Otherwise both must be specified.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
19.20.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I != J, the two cutoff distances for this pair style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the pair_modify shift option for the energy of the pair interaction.

This pair style does not support the pair_modify table option.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

19.20.5 Restrictions

These styles are part of the COLLOID package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

Only spherical monodisperse particles are allowed for pair_style brownian.

Only spherical particles are allowed for pair_style brownian/poly.

pair_coeff 1 1 100.0 1.5 200.0 9.0
```
19.24.3 Description

The buck style computes a Buckingham potential (exp/6 instead of Lennard-Jones 12/6) given by

\[ E = A e^{-r/\rho} - \frac{C}{r^6} \quad r < r_c \]

where \( \rho \) is an ionic-pair dependent length parameter, and \( r_c \) is the cutoff on both terms.

The styles with coul/cut or coul/long or coul/msm add a Coulombic term as described for the lj/cut pair styles. For buck/coul/long and buck/coul/msm, an additional damping factor is applied to the Coulombic term so it can be used in conjunction with the kspace_style command and its ewald or pppm or msm option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

If one cutoff is specified for the born/coul/cut and born/coul/long and born/coul/msm styles, it is used for both the A,C and Coulombic terms. If two cutoffs are specified, the first is used as the cutoff for the A,C terms, and the second is the cutoff for the Coulombic term.

Note that these potentials are related to the Born-Mayer-Huggins potential.

Note: For all these pair styles, the terms with A and C are always cutoff. The additional Coulombic term can be cutoff or long-range (no cutoff) depending on whether the style name includes coul/cut or coul/long or coul/msm. If you wish the C/r^6 term to be long-range (no cutoff), then see the pair_style buck/long/coul/long command.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands:

- A (energy units)
- \( \rho \) (distance units)
- C (energy-distance^6 units)
- cutoff (distance units)
- cutoff2 (distance units)

The second coefficient, \( \rho \), must be greater than zero. The coefficients A, \( \rho \), and C can be written as analytical expressions of \( \epsilon \) and \( \sigma \), in analogy to the Lennard-Jones potential (Khrapak).

The latter 2 coefficients are optional. If not specified, the global A,C and Coulombic cutoffs are used. If only one cutoff is specified, it is used as the cutoff for both A,C and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the A,C and Coulombic cutoffs for this type pair. You cannot specify 2 cutoffs for style buck, since it has no Coulombic terms. For buck/coul/long only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual I,J type pair. All type pairs use the same global Coulombic cutoff specified in the pair_style command.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.
See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

19.24.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.
These styles support the pair_modify shift option for the energy of the exp() and 1/r^6 portion of the pair interaction.
The buck/coul/long pair style supports the pair_modify table option to tabulate the short-range portion of the long-range Coulombic interaction.
These styles support the pair_modify tail option for adding long-range tail corrections to energy and pressure for the A,C terms in the pair interaction.
These styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.
These styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

19.24.5 Restrictions

The buck/coul/long style is part of the KSPACE package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

19.26.3 Description

The buck6d/coul/gauss styles evaluate vdW and Coulomb interactions following the MOF-FF force field after (Schmid).

The vdW term of the buck6d styles computes a dispersion damped Buckingham potential:

\[
E = A e^{-\kappa r} - \frac{C}{r^6} \cdot \frac{1}{1 + \frac{D}{r^{14}}} \quad r < r_c
\]

where A and C are a force constant, \( \kappa \) is an ionic-pair dependent reciprocal length parameter, D is a dispersion correction parameter, and the cutoff \( r_c \) truncates the interaction distance. The first term in the potential corresponds to the Buckingham repulsion term and the second term to the dispersion attraction with a damping correction analog to the Grimme correction used in DFT. The latter corrects for artifacts occurring at short distances which become an issue for soft vdW potentials.

The buck6d styles include a smoothing function which is invoked according to the global smoothing parameter within the specified cutoff. Hereby a parameter of i.e. 0.9 invokes the smoothing within 90% of the cutoff. No smoothing is applied at a value of 1.0. For the gauss/dsf style this smoothing is only applicable for the dispersion damped Buckingham potential. For the gauss/long styles the smoothing function can also be invoked for the real space coulomb interactions which enforce continuous energies and forces at the cutoff.

Both styles buck6d/coul/gauss/dsf and buck6d/coul/gauss/long evaluate a Coulomb potential using spherical Gaussian type charge distributions which effectively dampen electrostatic interactions for high charges at close distances. The electrostatic potential is thus evaluated as:

\[
E = \frac{C q_i q_j}{\varepsilon r_{ij}} \text{erf}(\alpha_{ij} r_{ij}) \quad r < r_c
\]

where C is an energy-conversion constant, \( q_i \) and \( q_j \) are the charges on the 2 atoms, \( \varepsilon \) is the dielectric constant which can be set by the dielectric command, \( \alpha \) is the ion pair dependent damping parameter and \( \text{erf}(\cdot) \) is the error-function. The cutoff \( r_c \) truncates the interaction distance.

The style buck6d/coul/gauss/dsf computes the Coulomb interaction via the damped shifted force model described in (Fennell) approximating an Ewald sum similar to the pair coul/dsf styles. In buck6d/coul/gauss/long an additional damping factor is applied to the Coulombic term so it can be used in conjunction with the kspace_style command and its ewald or pppm options. The Coulombic cutoff in this case separates the real and reciprocal space evaluation of the Ewald sum.
If one cutoff is specified it is used for both the vdW and Coulomb terms. If two cutoffs are specified, the first is used as the cutoff for the vdW terms, and the second is the cutoff for the Coulombic term.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands:

- A (energy units)
- $\rho$ (distance^-1 units)
- C (energy-distance^6 units)
- D (distance^14 units)
- $\alpha$ (distance^-1 units)
- cutoff (distance units)

The second coefficient, $\rho$, must be greater than zero. The latter coefficient is optional. If not specified, the global vdW cutoff is used.

### 19.26.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

These styles do not support the pair_modify shift option for the energy. Instead the smoothing function should be applied by setting the global smoothing parameter to a value < 1.0.

These styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

### 19.26.5 Restrictions

These styles are part of the MOFF package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

### 19.26.6 Related commands

pair_coeff

### 19.26.7 Default

19.27 pair_style buck/long/coul/long command

Accelerator Variants: buck/long/coul/long/omp

19.27.1 Syntax

```
pair_style buck/long/coul/long flag_buck flag_coul cutoff (cutoff2)
```

- **flag_buck** = *long* or *cut*
  - *long* = use Kspace long-range summation for the dispersion term \(1/r^6\)
  - *cut* = use a cutoff
- **flag_coul** = *long* or *off*
  - *long* = use Kspace long-range summation for the Coulombic term \(1/r\)
  - *off* = omit the Coulombic term
- **cutoff** = global cutoff for Buckingham (and Coulombic if only 1 cutoff) (distance units)
- **cutoff2** = global cutoff for Coulombic (optional) (distance units)

19.27.2 Examples

```
pair_style buck/long/coul/long cut off 2.5
pair_style buck/long/coul/long cut long 2.5 4.0
pair_style buck/long/coul/long long long 4.0
pair_coeff * * 1 1
pair_coeff 1 1 1 3 4
```

19.27.3 Description

The *buck/long/coul/long* style computes a Buckingham potential (exp/6 instead of Lennard-Jones 12/6) and Coulombic potential, given by

\[
E = Ae^{-r/\rho} - \frac{C}{r^6} \quad r < r_c
\]
\[
E = \frac{C q_i q_j}{e r} \quad r < r_c
\]

\(r_c\) is the cutoff. If one cutoff is specified in the pair_style command, it is used for both the Buckingham and Coulombic terms. If two cutoffs are specified, they are used as cutoffs for the Buckingham and Coulombic terms respectively.

The purpose of this pair style is to capture long-range interactions resulting from both attractive \(1/r^6\) Buckingham and Coulombic \(1/r\) interactions. This is done by use of the flag_buck and flag_coul settings. The Ismail paper has more details on when it is appropriate to include long-range \(1/r^6\) interactions, using this potential.

If flag_buck is set to *long*, no cutoff is used on the Buckingham \(1/r^6\) dispersion term. The long-range portion can be calculated by using the kspace_style ewald/disp or pppm/disp commands. The specified Buckingham cutoff then determines which portion of the Buckingham interactions are computed directly by the pair potential versus which part is computed in reciprocal space via the Kspace style. If flag_buck is set to *cut*, the Buckingham interactions are simply cutoff, as with pair_style buck.

If flag_coul is set to *long*, no cutoff is used on the Coulombic interactions. The long-range portion can be calculated by using any of several kspace_style command options such as pppm or ewald. Note that if flag_buck is also set to long,
then the ewald/disp or pppm/disp Kspace style needs to be used to perform the long-range calculations for both the Buckingham and Coulombic interactions. If flag_coul is set to off, Coulombic interactions are not computed.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands:

- A (energy units)
- rho (distance units)
- C (energy-distance^6 units)
- cutoff (distance units)
- cutoff2 (distance units)

The second coefficient, rho, must be greater than zero. The latter 2 coefficients are optional. If not specified, the global Buckingham and Coulombic cutoffs specified in the pair_style command are used. If only one cutoff is specified, it is used as the cutoff for both Buckingham and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the Buckingham and Coulombic cutoffs for this type pair. Note that if you are using flag_buck set to long, you cannot specify a Buckingham cutoff for an atom type pair, since only one global Buckingham cutoff is allowed. Similarly, if you are using flag_coul set to long, you cannot specify a Coulombic cutoff for an atom type pair, since only one global Coulombic cutoff is allowed.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

19.27.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

This pair style supports the pair_modify shift option for the energy of the exp() and 1/r^6 portion of the pair interaction, assuming flag_buck is cut.

This pair style does not support the pair_modify shift option for the energy of the Buckingham portion of the pair interaction.

This pair style supports the pair_modify table and table/disp options since they can tabulate the short-range portion of the long-range Coulombic and dispersion interactions.

This pair style write its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style supports the use of the inner, middle, and outer keywords of the run_style respa command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. See the run_style command for details.
19.27.5 Restrictions

This style is part of the KSPACE package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

(continues on next page)
19.33.3 Description

These pair styles compute Lennard Jones (LJ) and Coulombic interactions with additional switching or shifting functions that ramp the energy and/or force smoothly to zero between an inner and outer cutoff. They are implementations of the widely used CHARMM force field used in the CHARMM MD code (and others). See (MacKerell) for a description of the CHARMM force field.

The styles with charmm (not charmmfsw or charmmfsh) in their name are the older, original LAMMPS implementations. They compute the LJ and Coulombic interactions with an energy switching function (esw, shown in the formula below as $S(r)$), which ramps the energy smoothly to zero between the inner and outer cutoff. This can cause irregularities in pairwise forces (due to the discontinuous second derivative of energy at the boundaries of the switching region), which in some cases can result in detectable artifacts in an MD simulation.

The newer styles with charmmfsw or charmmfsh in their name replace the energy switching with force switching (fsw) and force shifting (fsh) functions, for LJ and Coulombic interactions respectively. These follow the formulas and description given in (Steinbach) and (Brooks) to minimize these artifacts.

**Note:** The newer charmmfsw or charmmfsh styles were released in March 2017. We recommend they be used instead of the older charmm styles. This includes the newer dihedral_style charmmfsw command. Eventually code from the new styles will propagate into the related pair styles (e.g. implicit, accelerator, free energy variants).

**Note:** The newest CHARMM pair styles reset the Coulombic energy conversion factor used internally in the code, from the LAMMPS value to the CHARMM value, as if it were effectively a parameter of the force field. This is because the CHARMM code uses a slightly different value for the this conversion factor in real units (Kcal/mole), namely CHARMM = 332.0716, LAMMPS = 332.06371. This is to enable more precise agreement by LAMMPS with the CHARMM force field energies and forces, when using one of these two CHARMM pair styles.

\[
E = \begin{cases} 
LJ(r) & r < r_{in} \\
S(r) \cdot LJ(r) & r_{in} < r < r_{out} \\
0 & r > r_{out} 
\end{cases}
\]

\[
LJ(r) = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right]
\]

\[
C(r) = \frac{C_q q_i \epsilon}{r}
\]

\[
S(r) = \frac{\left[ r_{out}^2 - r^2 \right]^2 \left[ r_{out}^2 + 2r^2 - 3r_{in}^2 \right]}{\left[ r_{out}^2 - r_{in}^2 \right]^3}
\]

where $S(r)$ is the energy switching function mentioned above for the charmm styles. See the (Steinbach) paper for the functional forms of the force switching and force shifting functions used in the charmmfsw and charmmfsh styles.

When using the lj/charmm/coul/charm styles, both the LJ and Coulombic terms require an inner and outer cutoff. They can be the same for both formulas or different depending on whether 2 or 4 arguments are used in the pair_style
command. For the \texttt{lj/charmmfsw/coul/charmmfsh} style, the LJ term requires both an inner and outer cutoff, while the Coulombic term requires only one cutoff. If the Coulombic cutoff is not specified (2 instead of 3 arguments), the LJ outer cutoff is used for the Coulombic cutoff. In all cases where an inner and outer cutoff are specified, the inner cutoff distance must be less than the outer cutoff. It is typical to make the difference between the inner and outer cutoffs about 2.0 Angstroms.

Style \texttt{lj/charmm/coul/charmm/implicit} computes the same formulas as style \texttt{lj/charmm/coul/charmm} except that an additional \(1/r\) term is included in the Coulombic formula. The Coulombic energy thus varies as \(1/r^2\). This is effectively a distance-dependent dielectric term which is a simple model for an implicit solvent with additional screening. It is designed for use in a simulation of an unsolvated biomolecule (no explicit water molecules).

Styles \texttt{lj/charmm/coul/long} and \texttt{lj/charmm/coul/msm} compute the same formulas as style \texttt{lj/charmm/coul/charmm} and style \texttt{lj/charmmfsw/coul/long} computes the same formulas as style \texttt{lj/charmmfsw/coul/charmmfsh}, except that an additional damping factor is applied to the Coulombic term, so it can be used in conjunction with the \texttt{kspace_style} command and its \texttt{ewald} or \texttt{pppm} or \texttt{msm} option. Only one Coulombic cutoff is specified for these styles; if only 2 arguments are used in the \texttt{pair_style} command, then the outer LJ cutoff is used as the single Coulombic cutoff. The Coulombic cutoff specified for these styles means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

The following coefficients must be defined for each pair of atoms types via the \texttt{pair_coeff} command as in the examples above, or in the data file or restart files read by the \texttt{read_data} or \texttt{read_restart} commands, or by mixing as described below:

- \(\epsilon\) (energy units)
- \(\sigma\) (distance units)
- \(\epsilon_{14}\) (energy units)
- \(\sigma_{14}\) (distance units)

Note that \(\sigma\) is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum at \(2^{1/6}\sigma\).

The latter 2 coefficients are optional. If they are specified, they are used in the LJ formula between 2 atoms of these types which are also first and fourth atoms in any dihedral. No cutoffs are specified because the CHARMM force field does not allow varying cutoffs for individual atom pairs; all pairs use the global cutoff(s) specified in the \texttt{pair_style} command.

Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \texttt{Accelerator packages} page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \texttt{Build package} page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \texttt{-suffix command-line switch} when you invoke LAMMPS, or you can use the \texttt{suffix} command in your input script.

See the \texttt{Accelerator packages} page for more instructions on how to use the accelerated styles effectively.
19.33.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs LJ and I != J, the epsilon, sigma, epsilon_14, and sigma_14 coefficients for all of the lj/charmm pair styles can be mixed. The default mix value is arithmetic to coincide with the usual settings for the CHARMM force field. See the “pair_modify” command for details.

None of the lj/charmm or lj/charmmfsw pair styles support the pair_modify shift option, since the Lennard-Jones portion of the pair interaction is smoothed to 0.0 at the cutoff.

The lj/charmm/coul/long and lj/charmmfsw/coul/long styles support the pair_modify table option since they can tabulate the short-range portion of the long-range Coulombic interaction.

None of the lj/charmm or lj/charmmfsw pair styles support the pair_modify tail option for adding long-range tail corrections to energy and pressure, since the Lennard-Jones portion of the pair interaction is smoothed to 0.0 at the cutoff.

All of the lj/charmm and lj/charmmfsw pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

The lj/charmm/coul/long and lj/charmmfsw/coul/long pair styles support the use of the inner, middle, and outer keywords of the run_style respa command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. The other styles only support the pair keyword of run_style respa. See the run_style command for details.

19.33.5 Restrictions

All the styles with coul/charmm or coul/charmmfsw styles are part of the MOLECULE package. All the styles with coul/long style are part of the KSPACE package. They are only enabled if LAMMPS was built with those packages. See the Build package doc page for more info.

```
19.36.3 Description

The \textit{lj/class2} styles compute a $6/9$ Lennard-Jones potential given by

$$E = \epsilon \left[ 2 \left( \frac{\sigma}{r} \right)^9 - 3 \left( \frac{\sigma}{r} \right)^6 \right] \quad r < r_c$$

$r_c$ is the cutoff.

The \textit{lj/class2/coul/cut} and \textit{lj/class2/coul/long} styles add a Coulombic term as described for the \textit{lj/cut} pair styles. See \textit{(Sun)} for a description of the COMPASS class2 force field.

The following coefficients must be defined for each pair of atoms types via the \textit{pair_coeff} command as in the examples above, or in the data file or restart files read by the \textit{read_data} or \textit{read_restart} commands, or by mixing as described below:

- $\epsilon$ (energy units)
- $\sigma$ (distance units)
- cutoff1 (distance units)
- cutoff2 (distance units)

The latter 2 coefficients are optional. If not specified, the global class 2 and Coulombic cutoffs are used. If only one cutoff is specified, it is used as the cutoff for both class 2 and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the class 2 and Coulombic cutoffs for this type pair. You cannot specify 2 cutoffs for style \textit{lj/class2}, since it has no Coulombic terms.

For \textit{lj/class2/coul/long} only the class 2 cutoff can be specified since a Coulombic cutoff cannot be specified for an individual LJ type pair. All type pairs use the same global Coulombic cutoff specified in the \textit{pair_style} command.

If the \textit{pair_coeff} command is not used to define coefficients for a particular $I \neq J$ type pair, the mixing rule for $\epsilon$ and $\sigma$ for all class2 potentials is to use the sixthpower formulas documented by the \textit{pair_modify} command. The \textit{pair_modify mix} setting is thus ignored for class2 potentials for epsilon and sigma. However it is still followed for mixing the cutoff distance.

A version of these styles with a soft core, \textit{lj/cut/soft}, suitable for use in free energy calculations, is part of the FEP package and is documented with the \textit{pair_style */soft} styles. The version with soft core is only available if LAMMPS was built with that package. See the \textit{Build package} page for more info.

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Accelerator packages} page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \textit{-suffix command-line switch} when you invoke LAMMPS, or you can use the \textit{suffix} command in your input script.

See the \textit{Accelerator packages} page for more instructions on how to use the accelerated styles effectively.
19.36.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I \neq J, the epsilon and sigma coefficients and cutoff distance for all of the lj/class2 pair styles can be mixed. Epsilon and sigma are always mixed with the value sixthpower. The cutoff distance is mixed by whatever option is set by the pair_modify command (default = geometric). See the “pair_modify” command for details.

All of the lj/class2 pair styles support the \textit{pair_modify} shift option for the energy of the Lennard-Jones portion of the pair interaction.

The \textit{lj/class2/coul/long} pair style does not support the \textit{pair_modify} table option since a tabulation capability has not yet been added to this potential.

All of the lj/class2 pair styles support the \textit{pair_modify} tail option for adding a long-range tail correction to the energy and pressure of the Lennard-Jones portion of the pair interaction.

All of the lj/class2 pair styles write their information to \textit{binary restart files}, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

Only the \textit{lj/class2} and \textit{lj/class2/coul/long} pair styles support the use of the \textit{inner}, \textit{middle}, and \textit{outer} keywords of the \textit{run_style respa} command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. The other styles only support the \textit{pair} keyword of run_style respa. See the \textit{run_style} command for details.

19.36.5 Restrictions

These styles are part of the CLASS2 package. They are only enabled if LAMMPS was built with that package. See the \textit{Build package} page for more info.

pair_coeff 2 2 39.478 1.0 10.0 10.0 25.0
```

19.37.3 Description

Style `colloid` computes pairwise interactions between large colloidal particles and small solvent particles using 3 formulas. A colloidal particle has a size $> \sigma$; a solvent particle is the usual Lennard-Jones particle of size $\sigma$.

The colloid-colloid interaction energy is given by

\[
U_{\text{A}} = \frac{-A_{\text{cc}}}{6} \left[ \frac{2a_1a_2}{r^2 - (a_1 + a_2)^2} + \frac{2a_1a_2}{r^2 - (a_1 - a_2)^2} + \ln \left( \frac{r^2 - (a_1 + a_2)^2}{r^2 - (a_1 - a_2)^2} \right) \right]
\]

\[
U_{\text{R}} = \frac{A_{\text{cc}}}{37800} \frac{a_6}{r} \left[ \frac{r^2 - 7r(a_1 + a_2) + 6(a_1^2 + 7a_1a_2 + a_2^2)}{(r - a_1 - a_2)^7} + \frac{r^2 + 7r(a_1 + a_2) + 6(a_1^2 + 7a_1a_2 + a_2^2)}{(r + a_1 + a_2)^7} \right]
\]

\[
U_{\text{cc}} = \frac{-A_{\text{cc}}}{6} \left[ \frac{r^2 - 7r(a_1 + a_2) + 6(a_1^2 + 7a_1a_2 + a_2^2)}{(r - a_1 - a_2)^7} + \frac{r^2 + 7r(a_1 - a_2) + 6(a_1^2 - 7a_1a_2 + a_2^2)}{(r + a_1 - a_2)^7} - \frac{r^2 - 7r(a_1 - a_2) + 6(a_1^2 - 7a_1a_2 + a_2^2)}{(r - a_1 + a_2)^7} \right]
\]

\[
U = U_{\text{A}} + U_{\text{R}}, \quad r < r_c
\]

where $A_{\text{cc}}$ is the Hamaker constant, $a_1$ and $a_2$ are the radii of the two colloidal particles, and $r_c$ is the cutoff. This equation results from describing each colloidal particle as an integrated collection of Lennard-Jones particles of size $\sigma$ and is derived in [Everaers](#). 

The colloid-solvent interaction energy is given by

\[
U = \frac{2a^3\sigma^3 A_{\text{cs}}}{9(a^2 - r^2)^3} \left[ 1 - \frac{(5a^6 + 45a^4r^2 + 63a^2r^4 + 15r^6)\sigma^6}{15(a - r)^6(a + r)^6} \right], \quad r < r_c
\]

where $A_{\text{cs}}$ is the Hamaker constant, $a$ is the radius of the colloidal particle, and $r_c$ is the cutoff. This formula is derived from the colloid-colloid interaction, letting one of the particle sizes go to zero.

The solvent-solvent interaction energy is given by the usual Lennard-Jones formula

\[
U = \frac{A_{\text{ss}}}{36} \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right], \quad r < r_c
\]

with $A_{\text{ss}}$ set appropriately, which results from letting both particle sizes go to zero.

When used in combination with `pair_style yukawa/colloid`, the two terms become the so-called DLVO potential, which combines electrostatic repulsion and van der Waals attraction.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:
• A (energy units)
• \( \sigma \) (distance units)
• \( d_1 \) (distance units)
• \( d_2 \) (distance units)
• cutoff (distance units)

A is the Hamaker energy prefactor and should typically be set as follows:

\[
\begin{align*}
A_{cc} &= \text{colloid/colloid} = 4\pi^2 = 39.5 \\
A_{cs} &= \text{colloid/solvent} = \sqrt{A_{cc}A_{ss}} \\
A_{ss} &= \text{solvent/solvent} = 144 \text{ (assuming } \epsilon = 1, \text{ so that } 144/36 = 4) \\
\end{align*}
\]

\( \sigma \) is the size of the solvent particle or the constituent particles integrated over in the colloidal particle and should typically be set as follows:

\[
\begin{align*}
\sigma_{cc} &= \text{colloid/colloid} = 1.0 \\
\sigma_{cs} &= \text{colloid/solvent} = \text{arithmetic mixing between colloid } \sigma \text{ and solvent } \sigma \\
\sigma_{ss} &= \text{solvent/solvent} = 1.0 \text{ or whatever size the solvent particle is} \\
\end{align*}
\]

Thus typically \( \sigma_{cs} = 1.0 \), unless the solvent particle’s size \( \neq 1.0 \).

\( d_1 \) and \( d_2 \) are particle diameters, so that \( d_1 = 2a_1 \) and \( d_2 = 2a_2 \) in the formulas above. Both \( d_1 \) and \( d_2 \) must be values \( \geq 0 \). If \( d_1 > 0 \) and \( d_2 > 0 \), then the pair interacts via the colloid-colloid formula above. If \( d_1 = 0 \) and \( d_2 = 0 \), then the pair interacts via the solvent-solvent formula. I.e. a \( d \) value of 0 is a Lennard-Jones particle of size \( \sigma \). If either \( d_1 = 0 \) or \( d_2 = 0 \) and the other is larger, then the pair interacts via the colloid-solvent formula.

Note that the diameter of a particular particle type may appear in multiple pair_coeff commands, as it interacts with other particle types. You should ensure the particle diameter is specified consistently each time it appears.

The last coefficient is optional. If not specified, the global cutoff specified in the pair_style command is used. However, you typically want different cutoffs for interactions between different particle sizes. E.g. if colloidal particles of diameter 10 are used with solvent particles of diameter 1, then a solvent-solvent cutoff of 2.5 would correspond to a colloid-colloid cutoff of 25. A good rule-of-thumb is to use a colloid-solvent cutoff that is half the big diameter + 4 times the small diameter. I.e. 9 = 5 + 4 for the colloid-solvent cutoff in this case.

**Note:** When using pair_style colloid for a mixture with 2 (or more) widely different particles sizes (e.g. \( \sigma = 10 \) colloids in a background \( \sigma = 1 \) LJ fluid), you will likely want to use these commands for efficiency: `neighbor multi` and `comm_modify multi`.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
19.37.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I!=J, the A, sigma, d1, and d2 coefficients and cutoff distance for this pair style can be mixed. A is an energy value mixed like a LJ epsilon. D1 and d2 are distance values and are mixed like sigma. The default mix value is geometric. See the “pair_modify” command for details.

This pair style supports the pair_modify shift option for the energy of the pair interaction.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

19.37.5 Restrictions

This style is part of the COLLOID package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

Normally, this pair style should be used with finite-size particles which have a diameter, e.g. see the atom_style sphere command. However, this is not a requirement, since the only definition of particle size is via the pair_coeff parameters for each type. In other words, the physical radius of the particle is ignored. Thus you should insure that the d1,d2 parameters you specify are consistent with the physical size of the particles of that type.

Per-particle polydispersity is not yet supported by this pair style; only per-type polydispersity is enabled via the pair_coeff parameters.

19.38 pair_style comb command

Accelerator Variants: comb/omp
19.39 pair_style comb3 command

19.39.1 Syntax

pair_style comb
pair_style comb3 keyword

keyword = polar
polar value = polar_on or polar_off = whether or not to include atomic polarization

19.39.2 Examples

pair_style comb
pair_coeff * * ../potentials/ffield.comb Si
pair_coeff * * ../potentials/ffield.comb Hf Si O

pair_style comb3 polar_off
pair_coeff * * ../potentials/ffield.comb3 O Cu N C O

19.39.3 Description

Style comb computes the second generation variable charge COMB (Charge-Optimized Many-Body) potential. Style comb3 computes the third-generation COMB potential. These COMB potentials are described in (COMB) and (COMB3). Briefly, the total energy $E_T$ of a system of atoms is given by

$$E_T = \sum_i E_i^{self}(q_i) + \sum_{j>i} [E_{ij}^{short}(r_{ij}, q_i, q_j) + E_{ij}^{Coul}(r_{ij}, q_i, q_j)] +$$

$$E_{ij}^{polar}(q_i, r_{ij}) + E_{ij}^{vdW}(r_{ij}) + E_{ij}^{barr}(q_i) + E_{ij}^{corr}(r_{ij}, \theta_{jik})$$

where $E_i^{self}$ is the self-energy of atom $i$ (including atomic ionization energies and electron affinities), $E_{ij}^{short}$ is the bond-order potential between atoms $i$ and $j$, $E_{ij}^{Coul}$ is the Coulomb interactions, $E_{ij}^{polar}$ is the polarization term for organic systems (style comb3 only), $E_{ij}^{vdW}$ is the van der Waals energy (style comb3 only), $E_{ij}^{barr}$ is a charge barrier function, and $E_{ij}^{corr}$ are angular correction terms.

The COMB potentials (styles comb and comb3) are variable charge potentials. The equilibrium charge on each atom is calculated by the electronegativity equalization (QEq) method. See Rick for further details. This is implemented by the fix qeq/comb command, which should normally be specified in the input script when running a model with the COMB potential. The fix qeq/comb command has options that determine how often charge equilibration is performed, its convergence criterion, and which atoms are included in the calculation.

Only a single pair_coeff command is used with the comb and comb3 styles which specifies the COMB potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the potential file in the pair_coeff command, where N is the number of LAMMPS atom types.

For example, if your LAMMPS simulation of a Si/SiO2/HfO2 interface has 4 atom types, and you want the first and last to be Si, the second to be Hf, and the third to be O, and you would use the following pair_coeff command:

pair_coeff * * ../potentials/ffield.comb Si Hf O Si

The first two arguments must be * * so as to span all LAMMPS atom types. The first and last Si arguments map LAMMPS atom types 1 and 4 to the Si element in the ffield.comb file. The second Hf argument maps LAMMPS atom type 2 to the Hf element, and the third O argument maps LAMMPS atom type 3 to the O element in the potential file.
If a mapping value is specified as NULL, the mapping is not performed. This can be used when a *comb* potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

For style *comb*, the provided potential file `ffield.comb` contains all currently-available second generation COMB parameterizations: for Si, Cu, Hf, Ti, O, their oxides and Zr, Zn and U metals. For style *comb3*, the potential file `ffield.comb3` contains all currently-available third generation COMB parameterizations: O, Cu, N, C, H, Ti, Zn and Zr. The status of the optimization of the compounds, for example Cu2O, TiN and hydrocarbons, are given in the following table:

<table>

</tr>
</tbody>
</table>

- **F** = Fully optimized
- **M** = Only optimized for dimer molecule
- **P** = in progress, but have it from mixing rule

For style *comb3*, in addition to `ffield.comb3`, a special parameter file, `lib.comb3`, that is exclusively used for C/O/H systems, will be automatically loaded if carbon atom is detected in LAMMPS input structure. This file must be in your working directory or in the directories listed in the environment variable `LAMMPS_POTENTIALS`, as described on the *pair_coeff* command doc page.

The keyword *polar* indicates whether the force field includes the atomic polarization. Since the equilibration of the polarization has not yet been implemented, it can only set polar_off at present.

**Note:** You can not use potential file `ffield.comb` with style *comb3*, nor file `ffield.comb3` with style *comb*.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix command-line switch* when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.
19.39.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I != J, where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

These pair styles does not support the `pair_modify` shift, table, and tail options.

These pair styles do not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the `pair_style`, `pair_coeff`, and `fix qeq/comb` commands in an input script that reads a restart file.

These pair styles can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

19.39.5 Restrictions

These pair styles are part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

These pair styles requires the `newton` setting to be “on” for pair interactions.

The COMB potentials in the `ffield.comb` and `ffield.comb3` files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the COMB potential with any LAMMPS units, but you would need to create your own COMB potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

19.39.6 Related commands

`pair_style`, `pair_coeff`, `fix qeq/comb`

19.39.7 Default

none

19.40 pair_style cosine/squared command

19.40.1 Syntax

```
pair_style cosine/squared cutoff
```

- cutoff = global cutoff for cosine-squared interactions (distance units)
pair_coeff i j eps sigma
cutoff
wca

- i,j = a particle type
- eps = interaction strength, i.e. the depth of the potential minimum (energy units)
- sigma = distance of the potential minimum from 0
- cutoff = the cutoff distance for this pair type, if different from global (distance units)
- wca = if specified a Weeks-Chandler-Andersen potential (with eps strength and minimum at sigma) is added, otherwise not

19.40.2 Examples

pair_style cosine/squared 3.0
pair_coeff * * 1.0 1.3
pair_coeff 1 3 1.0 1.3 2.0
pair_coeff 1 3 1.0 1.3 wca
pair_coeff 1 3 1.0 1.3 2.0 wca

19.40.3 Description

Style cosine/squared computes a potential of the form

\[
E = \begin{cases} 
-\epsilon & r < \sigma \\
-\epsilon \cos \left( \frac{\pi(r-\sigma)}{2(r_c-\sigma)} \right)^2 & \sigma \leq r < r_c \\
0 & r \geq r_c 
\end{cases}
\]

between two point particles, where \((\sigma, -\epsilon)\) is the location of the (rightmost) minimum of the potential, as explained in the syntax section above.

This potential was first used in (Cooke) for a coarse-grained lipid membrane model. It is generally very useful as a non-specific interaction potential because it is fully adjustable in depth and width while joining the minimum at \((\sigma, -\epsilon)\) and zero at \((cutoff, 0)\) smoothly, requiring no shifting and causing no related artifacts, tail energy calculations etc. This evidently requires cutoff to be larger than sigma.

If the wca option is used then a Weeks-Chandler-Andersen potential (Weeks) is added to the above specified cosine-squared potential, specifically the following:

\[
E = \epsilon \left( \frac{\sigma}{r} \right)^{12} - 2 \left( \frac{\sigma}{r} \right)^{6} + 1, \quad r < \sigma
\]

In this case, and this case only, the \(\sigma\) parameter can be equal to cutoff \((\sigma = cutoff)\) which will result in ONLY the WCA potential being used (and print a warning), so the minimum will be attained at \((\sigma, 0)\). This is a convenience feature that enables a purely repulsive potential to be used without a need to define an additional pair style and use the hybrid styles.

The energy and force of this pair style for parameters epsilon = 1.0, sigma = 1.0, cutoff = 2.5, with and without the WCA potential, are shown in the graphs below:
19.40.4 Mixing, shift, table, tail correction, restart, rRESPA info

Mixing is not supported for this style.

The *shift*, *table* and *tail* options are not relevant for this style.

This pair style writes its information to binary restart files, so *pair_style* and *pair_coeff* commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the *pair* keyword of the *run_style respa* command. They do not support the *inner*, *middle*, *outer* keywords.

19.40.5 Restrictions

The *cosine/squared* style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS is build with that package. See the *Build package* page for more info.

19.51.3 Description

The coul/cut style computes the standard Coulombic interaction potential given by

\[ E = \frac{C q_i q_j}{\epsilon r} r < r_c \]

where C is an energy-conversion constant, Qi and Qj are the charges on the 2 atoms, and \( \epsilon \) is the dielectric constant which can be set by the dielectric command. The cutoff \( r_c \) truncates the interaction distance.

Style coul/debye adds an additional exp() damping factor to the Coulombic term, given by

\[ E = \frac{C q_i q_j}{\epsilon r} \exp(-\kappa r) \quad r < r_c \]

where \( \kappa \) is the Debye length. This potential is another way to mimic the screening effect of a polar solvent.

Style coul/dsf computes Coulombic interactions via the damped shifted force model described in Fennell, given by:

\[ E = q_i q_j \left[ \frac{\text{erfc}(\alpha r)}{r} - \frac{\text{erfc}(\alpha r_c)}{r_c} + \left( \frac{\text{erfc}(\alpha r_c)}{r_c^2} + \frac{2\alpha}{\sqrt{\pi}} \exp(-\alpha^2 r_c^2) \right) (r - r_c) \right] \quad r < r_c \]

where \( \alpha \) is the damping parameter and erfc() is the complementary error-function. The potential corrects issues in the Wolf model (described below) to provide consistent forces and energies (the Wolf potential is not differentiable at the cutoff) and smooth decay to zero.

Style coul/wolf computes Coulombic interactions via the Wolf summation method, described in Wolf, given by:

\[ E_i = \frac{1}{2} \sum_{j \neq i} q_i q_j \frac{\text{erfc}(\alpha r_{ij})}{r_{ij}} + \frac{1}{2} \sum_{j \neq i} q_i q_j \frac{\text{erf}(\alpha r_{ij})}{r_{ij}} \quad r < r_c \]

where \( \alpha \) is the damping parameter, and erf() and erfc() are error-function and complementary error-function terms. This potential is essentially a short-range, spherically-truncated, charge-neutralized, shifted, pairwise \( 1/r \) summation. With a manipulation of adding and subtracting a self term (for \( i = j \)) to the first and second term on the right-hand-side, respectively, and a small enough \( \alpha \) damping parameter, the second term shrinks and the potential becomes a rapidly-converging real-space summation. With a long enough cutoff and small enough \( \alpha \) parameter, the energy and forces
calculated by the Wolf summation method approach those of the Ewald sum. So it is a means of getting effective long-range interactions with a short-range potential.

Style \texttt{coul/streitz} is the Coulomb pair interaction defined as part of the Streitz-Mintmire potential, as described in \textit{this paper}, in which charge distribution about an atom is modeled as a Slater 1$s$ orbital. More details can be found in the referenced paper. To fully reproduce the published Streitz-Mintmire potential, which is a variable charge potential, style \texttt{coul/streitz} must be used with \texttt{pair_style eam/alloy} (or some other short-range potential that has been parameterized appropriately) via the \texttt{pair_style hybrid/overlay} command. Likewise, charge equilibration must be performed via the \texttt{fix qeq/slater} command. For example:

\begin{verbatim}
pair_style hybrid/overlay coul/streitz 12.0 wolf 0.31 eam/alloy
pair_coeff * * coul/streitz AlO.streitz Al O
pair_coeff * * eam/alloy AlO.eam.alloy Al O
fix 1 all qeq/slater 1 12.0 1.0e-6 100 coul/streitz
\end{verbatim}

The keyword \texttt{wolf} in the \texttt{coul/streitz} command denotes computing Coulombic interactions via Wolf summation. An additional damping parameter is required for the Wolf summation, as described for the \texttt{coul/wolf} potential above. Alternatively, Coulombic interactions can be computed via an Ewald summation. For example:

\begin{verbatim}
pair_style hybrid/overlay coul/streitz 12.0 ewald eam/alloy
kspace_style ewald 1e-6
\end{verbatim}

Keyword \texttt{ewald} does not need a damping parameter, but a \texttt{kspace_style} must be defined, which can be style \texttt{ewald} or \texttt{pppm}. The Ewald method was used in Streitz and Mintmire's original paper, but a Wolf summation offers a speed-up in some cases.

For the \texttt{fix qeq/slater} command, the \texttt{qfile} can be a filename that contains QEq parameters as discussed on the \texttt{fix qeq} command doc page. Alternatively \texttt{qfile} can be replaced by "coul/streitz", in which case the \texttt{fix} will extract QEq parameters from the coul/streitz pair style itself.

See the examples/streitz directory for an example input script that uses the Streitz-Mintmire potential. The potentials directory has the AlO.eam.alloy and AlO.streitz potential files used by the example.

Note that the Streitz-Mintmire potential is generally used for oxides, but there is no conceptual problem with extending it to nitrides and carbides (such as SiC, TiN). Pair coul/streitz used by itself or with any other pair style such as EAM, MEAM, Tersoff, or LJ in hybrid/overlay mode. To do this, you would need to provide a Streitz-Mintmire parameterization for the material being modeled.

Pair style \texttt{coul/cut/global} computes the same Coulombic interactions as style \texttt{coul/cut} except that it allows only a single global cutoff and thus makes it compatible for use in combination with long-range coulomb styles in \textit{hybrid pair styles}.

Pair style \texttt{coul/exclude} computes Coulombic interactions like \texttt{coul/cut} but \textbf{only} applies them to excluded pairs using a scaling factor of $\gamma - 1.0$ with $\gamma$ being the factor assigned to that excluded pair via the \texttt{special_bonds coul} setting. With this it is possible to treat Coulomb interactions for molecular systems with \texttt{kspace_style scafacos}, which always computes the full Coulomb interactions without exclusions. Pair style \texttt{coul/exclude} will then subtract the excluded interactions accordingly. So to achieve the same forces as with \texttt{pair_style lj/cut/coul/long 12.0} with \texttt{kspace_style pppm 1.0e-6}, one would use \texttt{pair_style hybrid/overlay lj/cut 12.0 coul/exclude 12.0} with \texttt{kspace_style scafacos p3m 1.0e-6}.

Styles \texttt{tip4p/cut} and \texttt{tip4p/long} implement the Coulomb part of the TIP4P water model of (Jorgensen), which introduces a massless site located a short distance away from the oxygen atom along the bisector of the HOH angle. The atomic
types of the oxygen and hydrogen atoms, the bond and angle types for OH and HOH interactions, and the distance to the massless charge site are specified as pair_style arguments. Style tip4p/cut uses a global cutoff for Coulomb interactions; style tip4p/long is for use with a long-range Coulombic solver (Ewald or PPPM).

Note: For each TIP4P water molecule in your system, the atom IDs for the O and 2 H atoms must be consecutive, with the O atom first. This is to enable LAMMPS to “find” the 2 H atoms associated with each O atom. For example, if the atom ID of an O atom in a TIP4P water molecule is 500, then its 2 H atoms must have IDs 501 and 502.

See the How to tip4p page for more information on how to use the TIP4P pair styles and lists of parameters to set. Note that the neighbor list cutoff for Coulomb interactions is effectively extended by a distance 2*qdist when using the TIP4P pair style, to account for the offset distance of the fictitious charges on O atoms in water molecules. Thus it is typically best in an efficiency sense to use a LJ cutoff >= Coulombic cutoff + 2*qdist, to shrink the size of the neighbor list. This leads to slightly larger cost for the long-range calculation, so you can test the trade-off for your model.

Note that these potentials are designed to be combined with other pair potentials via the pair_style hybrid/overlay command. This is because they have no repulsive core. Hence if they are used by themselves, there will be no repulsion to keep two oppositely charged particles from moving arbitrarily close to each other.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data or restart files read by the read_data or read_restart commands, or by mixing as described below:

- cutoff (distance units)

For coul/cut and coul/debye the cutoff coefficient is optional. If it is not used (as in some of the examples above), the default global value specified in the pair_style command is used.

For coul/cut/global, coul/long and coul/msm no cutoff can be specified for an individual LJ type pair via the pair_coeff command. All type pairs use the same global Coulomb cutoff specified in the pair_style command.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

19.51.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I and J, the cutoff distance for the coul/cut style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

The pair_modify shift option is not relevant for these pair styles.

The coul/long style supports the pair_modify table option for tabulation of the short-range portion of the long-range Coulombic interaction.

These pair styles do not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.
These pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

## 19.51.5 Restrictions

The coul/cut/global, coul/long, coul/msm, coul/streitz, and tip4p/long styles are part of the KSPACE package. They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

```
pair_style coul/diel cutoff
```

cutoff = global cutoff (distance units)

### 19.52.2 Examples

```
pair_style coul/diel 3.5
pair_coeff 1 4 78. 1.375 0.112
```
19.52.3 Description

Style **coul/diel** computes a Coulomb correction for implicit solvent ion interactions in which the dielectric permittivity is distance dependent. The dielectric permittivity $\epsilon_D(r)$ connects to limiting regimes: One limit is defined by a small dielectric permittivity (close to vacuum) or close to contact separation between the ions. At larger separations the dielectric permittivity reaches a bulk value used in the regular Coulomb interaction coul/long or coul/cut. The transition is modeled by a hyperbolic function which is incorporated in the Coulomb correction term for small ion separations as follows

$$E = \frac{C q_i q_j}{\epsilon_D(r)} \left( \frac{\epsilon}{\epsilon_D(r)} - 1 \right) \quad r < r_c$$

$$\epsilon_D(r) = \frac{5.2 + \epsilon}{2} + \frac{\epsilon - 5.2}{2} \tanh \left( \frac{r - r_{me}}{\sigma_e} \right)$$

where $r_{me}$ is the inflection point of $\epsilon_D(r)$ and $\sigma_e$ is a slope defining length scale. $C$ is the same Coulomb conversion factor as in the pair_styles coul/cut, coul/long, and coul/debye. In this way the Coulomb interaction between ions is corrected at small distances $r$. The lower limit of $\epsilon_D(r \rightarrow 0)=5.2$ due to dielectric saturation (Stiles) while the Coulomb interaction reaches its bulk limit by setting $\epsilon_D(r \rightarrow \infty) = \epsilon$, the bulk value of the solvent which is 78 for water at 298K.

Examples of the use of this type of Coulomb interaction include implicit solvent simulations of salt ions (Lenart) and of ionic surfactants (Jusufi). Note that this potential is only reasonable for implicit solvent simulations and in combination with coul/cut or coul/long. It is also usually combined with gauss/cut, see (Lenart) or (Jusufi).

The following coefficients must be defined for each pair of atom types via the pair_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- $\epsilon$ (no units)
- $r_{me}$ (distance units)
- $\sigma_e$ (distance units)

The global cutoff ($r_c$) specified in the pair_style command is used.

19.52.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support parameter mixing. Coefficients must be given explicitly for each type of particle pairs.

This pair style supports the pair_modify shift option for the energy of the Gauss-potential portion of the pair interaction.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.
19.52.5 Restrictions

This style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

19.53 pair_style coul/shield command

19.53.1 Syntax

```
pair_style coul/shield cutoff tap_flag
```

- cutoff = global cutoff (distance units)
- tap_flag = 0/1 to turn off/on the taper function

19.53.2 Examples

```
pair_style coul/shield 16.0 1
pair_coeff 1 2 0.70
```

19.53.3 Description

Style coul/shield computes a Coulomb interaction for boron and nitrogen atoms located in different layers of hexagonal boron nitride. This potential is designed be used in combination with the pair style ilp/graphene/hbn.

Note: This potential is intended for electrostatic interactions between two different layers of hexagonal boron nitride. Therefore, to avoid interaction within the same layers, each layer should have a separate molecule id and is recommended to use the “full” atom style, so that charge and molecule ID information is included.
\[ E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij} \]

\[ V_{ij} = \text{Tap}(r_{ij}) \frac{\kappa q_i q_j}{\sqrt{r_{ij}^3 + (1/\lambda_{ij})^3}} \]

\[ \text{Tap}(r_{ij}) = 20 \left( \frac{r_{ij}}{R_{\text{cut}}} \right)^7 - 70 \left( \frac{r_{ij}}{R_{\text{cut}}} \right)^6 + 84 \left( \frac{r_{ij}}{R_{\text{cut}}} \right)^5 - 35 \left( \frac{r_{ij}}{R_{\text{cut}}} \right)^4 + 1 \]

Where \( \text{Tap}(r_{ij}) \) is the taper function which provides a continuous cutoff (up to third derivative) for inter-atomic separations larger than \( r_c \) \((\text{Leven1}), \text{(Leven2)}\) and \( \text{(Maaravi)} \). Here \( \lambda \) is the shielding parameter that eliminates the short-range singularity of the classical mono-polar electrostatic interaction expression \((\text{Maaravi})\).

The shielding parameter \( \lambda \) (1/distance units) must be defined for each pair of atom types via the \text{pair_coeff} command as in the example above, or in the data file or restart files read by the \text{read_data} or \text{read_restart} commands:

The global cutoff \( (r_c) \) specified in the \text{pair_style} command is used.

### 19.53.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support parameter mixing. Coefficients must be given explicitly for each type of particle pairs. The \text{pair_modify table} option is not relevant for this pair style.

This pair style does not support the \text{pair_modify tail} option for adding long-range tail corrections to energy and pressure. This pair style can only be used via the \text{pair} keyword of the \text{run_style respa} command. It does not support the \text{inner}, \text{middle}, \text{outer} keywords.

### 19.53.5 Restrictions

This pair style is part of the INTERLAYER package. It is only enabled if LAMMPS was built with that package. See the \text{Build package} page for more info.

19.54 pair_style coul/slater command

19.55 pair_style coul/slater/cut command

19.56 pair_style coul/slater/long command

19.56.1 Syntax

```
pair_style coul/slater/cut lambda cutoff
pair_style coul/slater/long lambda cutoff
```

lambda = decay length of the charge (distance units) cutoff = cutoff (distance units)

19.56.2 Examples

```
pair_style coul/slater/cut 1.0 3.5
pair_coeff * *
pair_coeff 2 2 2.5

pair_style coul/slater/long 1.0 12.0
pair_coeff * *
pair_coeff 1 1 5.0
```

19.56.3 Description

Styles `coul/slater` compute electrostatic interactions in mesoscopic models which employ potentials without explicit excluded-volume interactions. The goal is to prevent artificial ionic pair formation by including a charge distribution in the Coulomb potential, following the formulation of (Melchor):

\[
E = \frac{C q_i q_j}{\epsilon r} \left( 1 - \left(1 + \frac{r_{ij}}{\lambda} \exp\left(-2r_{ij}/\lambda\right)\right)\right) \quad r < r_c
\]

where \(r_c\) is the cutoff distance and \(\lambda\) is the decay length of the charge. \(C\) is the same Coulomb conversion factor as in the pair_styles coul/cut and coul/long. In this way the Coulomb interaction between ions is corrected at small distances \(r\). For the `coul/slater/cut` style, the potential energy for distances larger than the cutoff is zero, while for the `coul/slater/long`, the long-range interactions are computed either by the Ewald or the PPPM technique.

Phenomena that can be captured at a mesoscopic level using this type of electrostatic interactions include the formation of polyelectrolyte-surfactant aggregates, charge stabilization of colloidal suspensions, and the formation of complexes driven by charged species in biological systems. (Vaiwala).

The cutoff distance is optional. If it is not used, the default global value specified in the pair_style command is used. For each pair of atom types, a specific cutoff distance can be defined via the `pair_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \(r_c\) (distance units)

The global decay length of the charge \((\lambda)\) specified in the pair_style command is used for all pairs.
19.56.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I \neq J, the cutoff distance for the \textit{coul/slater} styles can be mixed. The default mix value is \textit{geometric}. See the “pair_modify” command for details.

The \textit{pair_modify} shift and table options are not relevant for these pair styles.

These pair styles do not support the \textit{pair_modify} tail option for adding long-range tail corrections to energy and pressure.

These pair styles write their information to \textit{binary restart files}, so pair\_style and pair\_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the \textit{pair} keyword of the \textit{run_style respa} command. It does not support the \textit{inner}, \textit{middle}, \textit{outer} keywords.

19.56.5 Restrictions

The \textit{coul/slater/long} style requires the long-range solvers included in the KSPACE package.

These styles are part of the EXTRA-PAIR package. They are only enabled if LAMMPS was built with that package. See the \textit{Build package} page for more info.

```

Example input scripts available: examples/PACKAGES/drude

19.57.3 Description

The `coul/tt` pair style is meant to be used with force fields that include explicit polarization through Drude dipoles.

The `coul/tt` pair style should be used as a sub-style within in the `pair_style hybrid/overlay` command, in conjunction with a main pair style including Coulomb interactions and `thole` pair style, or with `lj/cut/thole/long` pair style that is equivalent to the combination of preceding two.

The `coul/tt` pair styles compute the charge-dipole Coulomb interaction damped at short distances by a function

\[
f_{n,ij}(r) = 1 - c_{ij} \cdot e^{-b_{ij}r} \sum_{k=0}^{n} \frac{(b_{ij}r)^k}{k!}
\]

This function results from an adaptation to the Coulomb interaction (Salanne) of the damping function originally proposed by Tang Toennies for van der Waals interactions.

The polynomial takes the degree 4 for damping the Coulomb interaction. The parameters \( b_{ij} \) and \( c_{ij} \) could be determined from first-principle calculations for small, mainly mono-atomic, ions (Salanne), or else treated as empirical for large molecules.

In pair styles with Drude induced dipoles, this damping function is typically applied to the interactions between a Drude charge (either \( q_{D,i} \) on a Drude particle or \( -q_{D,i} \) on the respective Drude core)) and a charge on a non-polarizable atom, \( q_j \).

The Tang-Toennies function could also be used to damp electrostatic interactions between the (non-polarizable part of the) charge of a core, \( q_i - q_{D,i} \), and the Drude charge of another, \( -q_{D,j} \). The \( b_{ij} \) and \( c_{ij} \) are equal to \( b_{ji} \) and \( c_{ji} \) in the case of core-core interactions.

For pair_style `coul/tt`, the following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the example above.

- \( b_{ij} \)
- \( c_{ij} \)
- degree of polynomial (positive integer)
- cutoff (distance units)

The last two coefficients are optional. If not specified the global degree of the polynomial or the global cutoff specified in the pair_style command are used. In order to specify a cutoff (forth argument), the degree of the polynomial (third argument) must also be specified.
19.57.4 Mixing, shift, table, tail correction, restart, rRESPA info

The *coul/tt* pair style does not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

19.57.5 Restrictions

These pair styles are part of the DRUDE package. They are only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

This pair style should currently not be used with the *charmm dihedral style* if the latter has non-zero 1-4 weighting factors. This is because the *coul/tt* pair style does not know which pairs are 1-4 partners of which dihedrals.

```

(continues on next page)
These pair styles are designed to be used with the adiabatic core/shell model of (Mitchell and Finchham). See the Howto coreshell page for an overview of the model as implemented in LAMMPS.

All the styles are identical to the corresponding pair style without the “/cs” in the name:

- `pair_style born/coul/dsf`
- `pair_style born/coul/long`
- `pair_style born/coul/wolf`
- `pair_style buck/coul/long`
- `pair_style coul/long`
- `pair_style coul/wolf`
- `pair_style lj/cut/coul/long`
- `pair_style lj/class2/coul/long`

except that they correctly treat the special case where the distance between two charged core and shell atoms in the same core/shell pair approach $r = 0.0$.

Styles with a “/long” in the name are used with a long-range solver for Coulombic interactions via the `kspace_style` command. They require special treatment of the short-range Coulombic interactions within the core/shell model.

Specifically, the short-range Coulomb interaction between a core and its shell should be turned off using the `special_bonds` command by setting the 1-2 weight to 0.0, which works because the core and shell atoms are bonded to each other. This induces a long-range correction approximation which fails at small distances ($\sim 10^{-8}$). Therefore, the Coulomb term which is used to calculate the correction factor is extended by a minimal distance ($r_{min} = 1.0-6$) when the interaction between a core/shell pair is treated, as follows

$$E = \frac{Cq_iq_j}{\epsilon(r + r_{min})} \quad r \rightarrow 0$$
where $C$ is an energy-conversion constant, $q_i$ and $q_j$ are the charges on the core and shell, epsilon is the dielectric constant and $r_{\text{min}}$ is the minimal distance.

For styles that are not used with a long-range solver, i.e. those with “/dsf” or “/wolf” in the name, the only correction is the addition of a minimal distance to avoid the possible $r = 0.0$ case for a core/shell pair.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 19.65.4 Mixing, shift, table, tail correction, restart, rRESPA info

See the corresponding doc pages for pair styles without the “cs” suffix to see how mixing, shifting, tabulation, tail correction, restarting, and rRESPA are handled by theses pair styles.

### 19.65.5 Restrictions

These pair styles are part of the CORESHELL package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

```
19.72.3 Description

All these pair styles are derived from the corresponding pair styles without the `dielectric` suffix. In addition to computing atom forces and energies, these pair styles compute the electrical field vector at each atom, which are to be used in the `fix polarize` commands.

These pair styles should be used with `atom_style dielectric`, which uses atom charges rescaled by their local dielectric constant.

The styles `lj/cut/coul/long/dielectric`, `lj/cut/coul/msm/dielectric`, and `lj/long/coul/long/dielectric` should be used with their kspace style counterparts, namely, `pppm/dielectric`, `pppm/disp/dielectric`, and `msm/dielectric`, respectively.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

19.72.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distances for this pair style can be mixed. The default mix value is `geometric`. See the “pair_modify” command for details.

The `pair_modify` table option is not relevant for this pair style.

This pair style writes its information to binary restart files, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

19.72.5 Restrictions

These styles are part of the DIELECTRIC package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

19.76.3 Description

Style `lj/cut/dipole/cut` computes interactions between pairs of particles that each have a charge and/or a point dipole moment. In addition to the usual Lennard-Jones interaction between the particles (Elj) the charge-charge (Eqq), charge-dipole (Eqp), and dipole-dipole (Epp) interactions are computed by these formulas for the energy (E), force (F), and torque (T) between particles I and J.

\[
E_{LJ} = 4\epsilon \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6}
\]

\[
E_{qq} = \frac{q_i q_j}{r}
\]

\[
E_{qp} = \frac{q_i}{r^3} (p_i \cdot \vec{r})
\]

\[
E_{pp} = \frac{1}{r^3} (\vec{p}_i \cdot \vec{p}_j) - \frac{3}{r^5} (\vec{p}_i \cdot \vec{r})(\vec{p}_j \cdot \vec{r})
\]

\[
F_{qq} = \frac{q_i q_j}{r^3} \vec{r}
\]

\[
F_{qp} = -\frac{q_i}{r^3} \vec{p}_i + \frac{3 q_i}{r^5} (\vec{p}_i \cdot \vec{r}) \vec{r}
\]

\[
F_{pp} = \frac{3}{r^5} (\vec{p}_i \cdot \vec{p}_j) \vec{r} - \frac{15}{r^7} (\vec{p}_i \cdot \vec{r})(\vec{p}_j \cdot \vec{r}) \vec{r} + \frac{3}{r^7} [(\vec{p}_j \cdot \vec{r})\vec{p}_i + (\vec{p}_i \cdot \vec{r})\vec{p}_j]
\]

\[
T_{pq} = T_{ij} = \frac{q_i}{r^3} (\vec{p}_i \times \vec{r})
\]

\[
T_{qp} = T_{ji} = -\frac{q_i}{r^3} (\vec{p}_j \times \vec{r})
\]

\[
T_{pp} = T_{ij} = -\frac{1}{r^3} (\vec{p}_i \times \vec{p}_j) + \frac{3}{r^5} (\vec{p}_j \cdot \vec{r})(\vec{p}_i \times \vec{r})
\]

\[
T_{pp} = T_{ji} = -\frac{1}{r^3} (\vec{p}_j \times \vec{p}_i) + \frac{3}{r^5} (\vec{p}_i \cdot \vec{r})(\vec{p}_j \times \vec{r})
\]

where \(q_i\) and \(q_j\) are the charges on the two particles, \(\vec{p}_i\) and \(\vec{p}_j\) are the dipole moment vectors of the two particles, \(r\) is their separation distance, and the vector \(\vec{r} = \vec{R}_i - \vec{R}_j\) is the separation vector between the two particles. Note that Eqq
and Fqq are simply Coulombic energy and force, Fij = -Fji as symmetric forces, and Tij != -Tji since the torques do not act symmetrically. These formulas are discussed in (Allen) and in (Toukmany).

Also note, that in the code, all of these terms (except Elj) have a C/ε prefactor, the same as the Coulombic term in the LJ + Coulombic pair styles discussed here. C is an energy-conversion constant and epsilon is the dielectric constant which can be set by the dielectric command. The same is true of the equations that follow for other dipole pair styles.

Style \textit{lj/sf/dipole/sf} computes “shifted-force” interactions between pairs of particles that each have a charge and/or a point dipole moment. In general, a shifted-force potential is a (slightly) modified potential containing extra terms that make both the energy and its derivative go to zero at the cutoff distance; this removes (cutoff-related) problems in energy conservation and any numerical instability in the equations of motion (Allen). Shifted-force interactions for the Lennard-Jones (E_LJ), charge-charge (Eqq), charge-dipole (Eqp), dipole-charge (Epq) and dipole-dipole (Epp) potentials are computed by these formulas for the energy (E), force (F), and torque (T) between particles I and J:

\[
E_{\text{LJ}} = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right] + 6 \left( \frac{\sigma}{r_c} \right)^{12} - 3 \left( \frac{\sigma}{r_c} \right)^{6} \left( \frac{r}{r_c} \right)^2 - 7 \left( \frac{\sigma}{r_c} \right)^{12} + 4 \left( \frac{\sigma}{r_c} \right)^{6}
\]

\[
E_{\text{qq}} = \frac{q_i q_j}{r} \left( 1 - \frac{r}{r_c} \right)^2
\]

\[
E_{\text{pq}} = E_{\text{qp}} = \frac{q_i}{r^3} \left[ 1 - 3 \left( \frac{r}{r_c} \right)^2 + 2 \left( \frac{r}{r_c} \right)^3 \right] \vec{p}_i \cdot \vec{r}
\]

\[
E_{\text{pp}} = \left[ 1 - 4 \left( \frac{r}{r_c} \right)^3 + 3 \left( \frac{r}{r_c} \right)^4 \right] \left[ \frac{1}{r^3} \left( \vec{p}_i \cdot \vec{p}_j \right) - \frac{3}{r^5} \left( \vec{p}_i \cdot \vec{r} \right) \left( \vec{p}_j \cdot \vec{r} \right) \right]
\]
The following coefficients must be defined for each pair of atom types via the `pair_coeff` command or in the “Atoms” section of the data file read in by the `read_data` command. The `fix nvt/sphere update` command can be used to monitor the temperature, since it includes rotational degrees of freedom. The `omega` option on the `fix langevin` command can be used to thermostat the rotational motion. The `compute temp/sphere` command can be used to monitor the temperature, since it includes rotational degrees of freedom. The `atom_style hybrid dipole sphere` command should be used since it defines the point dipoles and their rotational state. The magnitude and orientation of the dipole moment for each particle can be defined by the `set` command or in the “Atoms” section of the data file read in by the `read_data` command.

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples:

\[
T_{pq} = T_{ij} = \frac{q_i q_j}{r_{ij}^3} \left[ 1 - 3 \left( \frac{r_{ij}}{r_c} \right)^2 + 2 \left( \frac{r_{ij}}{r_c} \right)^3 \right] (\vec{p}_i \times \vec{r})
\]

\[
T_{qp} = T_{ji} = -\frac{q_i q_j}{r_{ij}^3} \left[ 1 - 3 \left( \frac{r_{ij}}{r_c} \right)^2 + 2 \left( \frac{r_{ij}}{r_c} \right)^3 \right] (\vec{p}_j \times \vec{r})
\]

\[
T_{pp} = T_{ij} = -\frac{1}{r_{ij}^4} \left[ 1 - 4 \left( \frac{r_{ij}}{r_c} \right)^3 + 6 \left( \frac{r_{ij}}{r_c} \right)^4 \right] (\vec{p}_i \times \vec{r})
\]

where \( \epsilon \) and \( \sigma \) are the standard LJ parameters, \( r_c \) is the cutoff, \( q_i \) and \( q_j \) are the charges on the two particles, \( \vec{p}_i \) and \( \vec{p}_j \) are the dipole moment vectors of the two particles, \( r_{ij} \) is their separation distance, and the vector \( \vec{r} = \vec{R}_i - \vec{R}_j \) is the separation vector between the two particles. Note that Eqq and Fqq are simply Coulombic energy and force, \( F_{ij} = -F_{ji} \) as symmetric forces, and \( T_{ij} \neq -T_{ji} \) since the torques do not act symmetrically. The shifted-force formula for the Lennard-Jones potential is reported in (Stoddard). The original (non-shifted) formulas for the electrostatic potentials, forces and torques can be found in (Price). The shifted-force electrostatic potentials have been obtained by applying equation 5.13 of (Allen). The formulas for the corresponding forces and torques have been obtained by applying the ‘chain rule’ as in appendix C.3 of (Allen).

If one cutoff is specified in the `pair_style` command, it is used for both the LJ and Coulombic (q,p) terms. If two cutoffs are specified, they are used as cutoffs for the LJ and Coulombic (q,p) terms respectively. This pair style also supports an optional `scale` keyword as part of a `pair_coeff` statement, where the interactions can be scaled according to this factor. This scale factor is also made available for use with `fix adapt`.

Style `lj/cut/dipole/long` computes long-range point-dipole interactions as discussed in (Toukmaji). Dipole-dipole, dipole-charge, and charge-charge interactions are all supported, along with the standard 12/6 Lennard-Jones interactions, which are computed with a cutoff. A `kspace_style` must be defined to use this pair style. Currently, only `kspace_style ewald/disp` support long-range point-dipole interactions.

Style `lj/long/dipole/long` also computes point-dipole interactions as discussed in (Toukmaji). Long-range dipole-dipole, dipole-charge, and charge-charge interactions are all supported, along with the standard 12/6 Lennard-Jones interactions. LJ interactions can be cutoff or long-ranged.

For style `lj/long/dipole/long`, if `flag_lj` is set to `long`, no cutoff is used on the LJ 1/r^6 dispersion term. The long-range portion is calculated by using the `kspace_style ewald Disp` command. The specified LJ cutoff then determines which portion of the LJ interactions are computed directly by the pair potential versus which part is computed in reciprocal space via the Kspace style. If `flag_lj` is set to `cut`, the LJ interactions are simply cutoff, as with `pair_style lj/cut`. If `flag_lj` is set to `off`, LJ interactions are not computed at all.

If `flag_coul` is set to `long`, no cutoff is used on the Coulombic or dipole interactions. The long-range portion is calculated by using `ewald Disp` of the `kspace_style` command. If `flag_coul` is set to `off`, Coulombic and dipole interactions are not computed at all.

Atoms with dipole moments should be integrated using the `fix nve/sphere update dipole` or the `fix nvt/sphere update dipole` command to rotate the dipole moments. The `omega` option on the `fix langevin` command can be used to thermostat the rotational motion. The `compute temp/sphere` command can be used to monitor the temperature, since it includes rotational degrees of freedom. The `atom_style hybrid dipole sphere` command should be used since it defines the point dipoles and their rotational state. The magnitude and orientation of the dipole moment for each particle can be defined by the `set` command or in the “Atoms” section of the data file read in by the `read_data` command.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples:

19.76. `pair_style lj/long/dipole/long` command 1965
above, or in the data file or restart files read by the \texttt{read_data} or \texttt{read_restart} commands, or by mixing as described below:

- $\epsilon$ (energy units)
- $\sigma$ (distance units)
- cutoff1 (distance units)
- cutoff2 (distance units)

The latter 2 coefficients are optional. If not specified, the global LJ and Coulombic cutoffs specified in the pair\_style command are used. If only one cutoff is specified, it is used as the cutoff for both LJ and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the LJ and Coulombic cutoffs for this type pair.

Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \texttt{Accelerator packages} page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \texttt{Build package} page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \texttt{-suffix} command-line switch when you invoke LAMMPS, or you can use the \texttt{suffix} command in your input script.

See the \texttt{Accelerator packages} page for more instructions on how to use the accelerated styles effectively.

\section{Mixing, shift, table, tail correction, restart, rRESPA info}

For atom type pairs $I,J$ and $I \neq J$, the epsilon and sigma coefficients and cutoff distances for this pair style can be mixed. The default mix value is \texttt{geometric}. See the “pair\_modify” command for details.

For atom type pairs $I,J$ and $I \neq J$, the $A$, sigma, $d_1$, and $d_2$ coefficients and cutoff distance for this pair style can be mixed. $A$ is an energy value mixed like a LJ epsilon. $D_1$ and $d_2$ are distance values and are mixed like sigma. The default mix value is \texttt{geometric}. See the “pair\_modify” command for details.

This pair style does not support the \texttt{pair\_modify} shift option for the energy of the Lennard-Jones portion of the pair interaction; such energy goes to zero at the cutoff by construction.

The \texttt{pair\_modify} table option is not relevant for this pair style.

This pair style does not support the \texttt{pair\_modify} tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to \texttt{binary restart files}, so pair\_style and pair\_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the \texttt{pair} keyword of the \texttt{run\_style respa} command. It does not support the \texttt{inner}, \texttt{middle}, \texttt{outer} keywords.
19.76.5 Restrictions

The lj/cut/dipole/cut, lj/cut/dipole/long, lj/long/dipole/long, and lj/sf/dipole/sf* styles are part of the DIPOLE package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

Using dipole pair styles with electron units is not currently supported.

19.78.3 Description

Style dpd computes a force field for dissipative particle dynamics (DPD) following the exposition in (Groot).

Style dpd/tstat invokes a DPD thermostat on pairwise interactions, which is equivalent to the non-conservative portion of the DPD force field. This pairwise thermostat can be used in conjunction with any pair style, and in lieu of per-particle thermostats like fix langevin or ensemble thermostats like Nose Hoover as implemented by fix nvt. To use dpd/tstat as a thermostat for another pair style, use the pair_style hybrid/overlay command to compute both the desired pair interaction and the thermostat for each pair of particles.

For style dpd, the force on atom I due to atom J is given as a sum of 3 terms

\[
\vec{f} = (F^C + F^D + F^R)r_{ij} \quad r < r_c
\]

\[
F^C = Aw(r)
\]

\[
F^D = -\gamma w^2(r)(\vec{r}_{ij} \cdot \vec{v}_{ij})
\]

\[
F^R = \sigma w(r)\alpha(\Delta t)^{-1/2}
\]

\[
w(r) = 1 - r/r_c
\]

where \(F^C\) is a conservative force, \(F^D\) is a dissipative force, and \(F^R\) is a random force. \(r_{ij}\) is a unit vector in the direction \(\vec{r}_i - \vec{r}_j\), \(v_{ij}\) is the vector difference in velocities of the two atoms = \(\vec{v}_i - \vec{v}_j\), \(\alpha\) is a Gaussian random number with zero mean and unit variance, \(\Delta t\) is the timestep size, and \(w(r)\) is a weighting factor that varies between 0 and 1. \(r_c\) is the cutoff. \(\sigma\) is set equal to \(\sqrt{2k_B T \gamma}\), where \(k_B\) is the Boltzmann constant and \(T\) is the temperature parameter in the pair_style command.

For style dpd/tstat, the force on atom I due to atom J is the same as the above equation, except that the conservative \(F_c\) term is dropped. Also, during the run, \(T\) is set each timestep to a ramped value from \(T_{start}\) to \(T_{stop}\).

For style dpd, the pairwise energy associated with style dpd is only due to the conservative force term \(F_c\), and is shifted to be zero at the cutoff distance \(R_c\). The pairwise virial is calculated using all 3 terms. For style dpd/tstat there is no pairwise energy, but the last two terms of the formula make a contribution to the virial.

For style dpd, the following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands:

- A (force units)
- \(\gamma\) (force/velocity units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global DPD cutoff is used. Note that sigma is set equal to \(\sqrt{2k_B T \gamma}\), where \(T\) is the temperature set by the pair_style command so it does not need to be specified.

For style dpd/tstat, the coefficients defined for each pair of atoms types via the pair_coeff command is the same, except that \(A\) is not included.

The GPU-accelerated versions of these styles are implemented based on the work of (Afshar) and (Phillips).
Note: If you are modeling DPD polymer chains, you may want to use the pair_style srp command in conjunction with these pair styles. It is a soft segmental repulsive potential (SRP) that can prevent DPD polymer chains from crossing each other.

Note: The virial calculation for pressure when using these pair styles includes all the components of force listed above, including the random force. Since the random force depends on random numbers, everything that changes the order of atoms in the neighbor list (e.g. different number of MPI ranks or a different neighbor list skin distance) will also change the sequence in which the random numbers are applied and thus the individual forces and therefore also the virial/pressure.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script. See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

19.78.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

These pair styles do not support the pair_modify shift option for the energy of the pair interaction. Note that as discussed above, the energy due to the conservative Fc term is already shifted to be 0.0 at the cutoff distance Rc.

The pair_modify table option is not relevant for these pair styles.

These pair styles do not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

These pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file. Note that the user-specified random number seed is stored in the restart file, so when a simulation is restarted, each processor will re-initialize its random number generator the same way it did initially. This means the random forces will be random, but will not be the same as they would have been if the original simulation had continued past the restart time.

These pair styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

The dpd/tstat style can ramp its target temperature over multiple runs, using the start and stop keywords of the run command. See the run command for details of how to do this.
19.78.5 Restrictions

These styles are part of the DPD-BASIC package. They are only enabled if LAMMPS was built with that package. See the `Build package` page for more info.

The default frequency for rebuilding neighbor lists is every 10 steps (see the `neigh_modify` command). This may be too infrequent for style `dpd` simulations since particles move rapidly and can overlap by large amounts. If this setting yields a non-zero number of “dangerous” reneighborings (printed at the end of a simulation), you should experiment with forcing reneighboring more often and see if system energies/trajectories change.

These pair styles requires you to use the `comm_modify vel yes` command so that velocities are stored by ghost atoms.

These pair styles will not restart exactly when using the `read_restart` command, though they should provide statistically similar results. This is because the forces they compute depend on atom velocities. See the `read_restart` command for more details.

---

19.79 pair_style dpd/ext command

Accelerator Variants: dpd/ext/kk

19.80 pair_style dpd/ext/tstat command

Accelerator Variants: dpd/ext/tstat/kk

19.80.1 Syntax

```
pair_style dpd/ext T cutoff seed
pair_style dpd/ext/tstat Tstart Tstop cutoff seed
```

- `T` = temperature (temperature units)
- `Tstart,Tstop` = desired temperature at start/end of run (temperature units)
- `cutoff` = global cutoff for DPD interactions (distance units)
- `seed` = random # seed (positive integer)
The style `dpd/ext` computes an extended force field for dissipative particle dynamics (DPD) following the exposition in *(Groot), *(Junghans).

Style `dpd/ext/tstat` invokes an extended DPD thermostat on pairwise interactions, equivalent to the non-conservative portion of the extended DPD force field. To use `dpd/ext/tstat` as a thermostat for another pair style, use the `pair_style` `hybrid/overlay` command to compute both the desired pair interaction and the thermostat for each pair of particles.

For the style `dpd/ext`, the force on atom I due to atom J is given as a sum of 3 terms

\[
\mathbf{f} = f^C + f^D + f^R \quad r < r_c
\]

\[
f^C = A_{ij} w(r) \hat{r}_{ij}
\]

\[
f^D = -\gamma_\parallel w_\parallel^2(r)(\hat{r}_{ij} \cdot \mathbf{v}_{ij})\hat{r}_{ij} - \gamma_\perp w_\perp^2(r)(\mathbf{I} - \hat{r}_{ij}\hat{r}_{ij}^T)\mathbf{v}_{ij}
\]

\[
f^R = \sigma_\parallel w_\parallel(r)\frac{\alpha}{\sqrt{\Delta t}} \hat{r}_{ij} + \sigma_\perp w_\perp(r)(\mathbf{I} - \hat{r}_{ij}\hat{r}_{ij}^T)\xi_{ij}\frac{1}{\sqrt{\Delta t}}
\]

\[
w(r) = 1 - r/r_c
\]

where \(f^C\) is a conservative force, \(f^D\) is a dissipative force, and \(f^R\) is a random force. \(A_{ij}\) is the maximum repulsion between the two atoms, \(\hat{r}_{ij}\) is a unit vector in the direction \(\mathbf{r}_i - \mathbf{r}_j\), \(\mathbf{v}_{ij} = \mathbf{v}_i - \mathbf{v}_j\) is the vector difference in velocities of the two atoms, \(\alpha\) and \(\xi_{ij}\) are Gaussian random numbers with zero mean and unit variance, \(\Delta t\) is the timestep, \(w(r) = 1 - r/r_c\) is a weight function for the conservative interactions that varies between 0 and 1, \(r_c\) is the corresponding cutoff, \(w_\parallel(r) = (1 - r/r_c)\alpha_\parallel\), \(\alpha \equiv (||, \perp)\), are weight functions with coefficients \(s_\alpha\) that vary between 0 and 1, \(r_c\) is the corresponding cutoff, \(\mathbf{I}\) is the unit matrix, \(\sigma_\alpha = \sqrt{2kT\gamma_\alpha}\), where \(k\) is the Boltzmann constant and \(T\) is the temperature in the pair_style command.

For the style `dpd/ext/tstat`, the force on atom I due to atom J is the same as the above equation, except that the conservative \(f^C\) term is dropped. Also, during the run, \(T\) is set each timestep to a ramped value from Tstart to Tstop.

For the style `dpd/ext`, the pairwise energy associated with style `dpd/ext` is only due to the conservative force term \(f^C\), and is shifted to be zero at the cutoff distance \(r_c\). The pairwise virial is calculated using all three terms. There is no pairwise energy for style `dpd/ext/tstat`, but the last two terms of the formula contribute the virial.

For the style `dpd/ext/tstat`, the force on atom I due to atom J is the same as the above equation, except that the conservative \(f^C\) term is dropped. Also, during the run, \(T\) is set each timestep to a ramped value from Tstart to Tstop.

For the style `dpd/ext`, the pairwise energy associated with style `dpd/ext` is only due to the conservative force term \(f^C\), and is shifted to be zero at the cutoff distance \(r_c\). The pairwise virial is calculated using all three terms. There is no pairwise energy for style `dpd/ext/tstat`, but the last two terms of the formula contribute the virial.

For the style `dpd/ext`, the following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above:

- \(A\) (force units)
- \(\gamma_\perp\) (force/velocity units)

---

**19.80. pair_style dpd/ext/tstat command**
The last coefficient is optional. If not specified, the global DPD cutoff is used. Note that $\sigma$’s are set equal to $\sqrt{2kT\gamma}$, where $T$ is the temperature set by the `pair_style` command so it does not need to be specified.

For the style `dpd/ext/tstat`, the coefficients defined for each pair of atoms types via the `pair_coeff` command is the same, except that $A$ is not included.

**Note:** If you are modeling DPD polymer chains, you may want to use the `pair_style srp` command in conjunction with these pair styles. It is a soft segmental repulsive potential (SRP) that can prevent DPD polymer chains from crossing each other.

**Note:** The virial calculation for pressure when using this pair style includes all the components of force listed above, including the random force.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

**Mixing, shift, table, tail correction, restart, rRESPA info:**

The style `dpd/ext` does not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

The pair styles do not support the `pair_modify` shift option for the energy of the pair interaction. Note that as discussed above, the energy due to the conservative $f^C$ term is already shifted to be zero at the cutoff distance $r_c$.

The `pair_modify` table option is not relevant for the style `dpd/ext`.

The style `dpd/ext` does not support the `pair_modify` tail option for adding long-range tail corrections to energy and pressure.

The pair styles can only be used via the pair keyword of the `run_style respa` command. They do not support the `inner`, `middle`, and `outer` keywords.

The style `dpd/ext/tstat` can ramp its target temperature over multiple runs, using the start and stop keywords of the `run` command. See the `run` command for details of how to do this.
19.80.4 Restrictions

These styles are part of the DPD-BASIC package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

The default frequency for rebuilding neighbor lists is every 10 steps (see the neigh_modify command). This may be too infrequent for style dpd/ext simulations since particles move rapidly and can overlap by large amounts. If this setting yields a non-zero number of say, dangerous, reneighborings (printed at the end of a simulation), you should experiment with forcing reneighboring more often and see if system energies/trajectories change.

The pair styles require to use the comm_modify vel yes command so that velocities are stored by ghost atoms.

The pair styles will not restart exactly when using the read_restart command, though they should provide statistically similar results. This is because the forces they compute depend on atom velocities. See the read_restart command for more details.

```

19.82.3 Description

Styles `dpd/fdt` and `dpd/fdt/energy` compute the force for dissipative particle dynamics (DPD) simulations. The `dpd/fdt` style is used to perform DPD simulations under isothermal and isobaric conditions, while the `dpd/fdt/energy` style is used to perform DPD simulations under isoenergetic and isenthalpic conditions (see (Lisal)). For DPD simulations in general, the force on atom I due to atom J is given as a sum of 3 terms

\[
\vec{f} = (F^C + F^D + F^R) \hat{r}_{ij}
\]

where \(F^C\) is a conservative force, \(F^D\) is a dissipative force, and \(F^R\) is a random force. \(r_{ij}\) is a unit vector in the direction \(r_i - r_j\), \(V_{ij}\) is the vector difference in velocities of the two atoms:

\[
F^C = A w(r)
F^D = -\gamma w^2(r)(\hat{r}_{ij} \cdot \vec{v}_{ij})
F^R = \sigma w(r)\alpha(\Delta t)^{-1/2}
\]

\(w(r) = 1 - r/r_c\)

\(\alpha\) is a Gaussian random number with zero mean and unit variance, \(\Delta t\) is the timestep size, and \(w(r)\) is a weighting factor that varies between 0 and 1. \(R_c\) is the cutoff. The weighting factor, \(\omega_{ij}\), varies between 0 and 1, and is chosen to have the following functional form:

\[
\omega_{ij} = 1 - \frac{r_{ij}}{r_c}
\]

Note that alternative definitions of the weighting function exist, but would have to be implemented as a separate pair style command.

For style `dpd/fdt`, the fluctuation-dissipation theorem defines \(\gamma\) to be set equal to \(\sigma^2/(2T)\), where T is the set point temperature specified as a pair style parameter in the above examples. The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \(A\) (force units)
- \(\sigma\) (force*time^*(1/2) units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global DPD cutoff is used.

Style `dpd/fdt/energy` is used to perform DPD simulations under isoenergetic and isenthalpic conditions. The fluctuation-dissipation theorem defines \(\gamma\) to be set equal to \(\sigma^2/(2\theta)\), where :math:`\theta` is the average internal temperature for the pair. The particle internal temperature is related to the particle internal energy through a mesoscopic equation of state (see fix eos). The differential internal conductive and mechanical energies are computed within style `dpd/fdt/energy` as:

\[
d u_{cond}^i = k_i (\frac{1}{\theta_i} - \frac{1}{\theta_j}) \omega_{ij}^2 + \alpha_{ij} \omega_{ij} \zeta_{ij} (\Delta t)^{-1/2}
\]

\[
d u_{mech}^i = -\frac{1}{2} \gamma_{ij} \omega_{ij}^2 (\frac{\hat{r}_{ij}}{r_{ij}} \cdot \vec{v}_{ij}) - \frac{1}{2} \sigma_{ij} \omega_{ij} (\frac{\hat{r}_{ij}}{r_{ij}} \cdot \vec{v}_{ij}) \zeta_{ij} (\Delta t)^{-1/2}
\]
where
\[
\alpha_{ij}^2 = 2k_B\kappa_{ij} \\
\sigma_{ij}^2 = 2\gamma_{ij}k_B\Theta_{ij} \\
\Theta_{ij}^{-1} = \frac{1}{2}\left(\frac{1}{\theta_i} + \frac{1}{\theta_j}\right)
\]
ζ_ij^q is a second Gaussian random number with zero mean and unit variance that is used to compute the internal conductive energy. The fluctuation-dissipation theorem defines \(\alpha^2\) to be set equal to \(2k_B\kappa\), where \(\kappa\) is the mesoparticle thermal conductivity parameter. The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands:

- A (force units)
- \(\sigma\) (force*time^(1/2) units)
- \(\kappa\) (energy*temperature/time units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global DPD cutoff is used.

The pairwise energy associated with styles dpdfdt and dpdfdt/energy is only due to the conservative force term \(F_c\), and is shifted to be zero at the cutoff distance \(R_c\). The pairwise virial is calculated using only the conservative term.

The forces computed through the dpdfdt and dpdfdt/energy styles can be integrated with the velocity-Verlet integration scheme or the Shardlow splitting integration scheme described by (Lisal). In the cases when these pair styles are combined with the fix shardlow, these pair styles differ from the other dpd styles in that the dissipative and random forces are split from the force calculation and are not computed within the pair style. Thus, only the conservative force is computed by the pair style, while the stochastic integration of the dissipative and random forces are handled through the Shardlow splitting algorithm approach. The Shardlow splitting algorithm is advantageous, especially when performing DPD under isoenergetic conditions, as it allows significantly larger timesteps to be taken.

Styles with a \(\text{gpu}, \text{intel}, \text{kk}, \text{omp}, \text{or opt}\) suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 19.82.4 Restrictions

These commands are part of the DPD-REACT package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

Pair styles dpdfdt and dpdfdt/energy require use of the \text{comm_modify vel yes} option so that velocities are stored by ghost atoms.

Pair style dpdfdt/energy requires \text{atom_style dpd} to be used in order to properly account for the particle internal energies and temperatures.

\]

19.83.3 Description

Style \textit{drip} computes the interlayer interactions of layered materials using the dihedral-angle-corrected registry-dependent (DRIP) potential as described in (Wen), which is based on the (Kolmogorov) potential and provides an improved prediction for forces. The total potential energy of a system is

\[
E = \frac{1}{2} \sum_i \sum_{j \in \text{layer } i} \phi_{ij}
\]

\[
\phi_{ij} = f_c(x_r) \left[ e^{-\lambda (r_{ij} - z_0)} \left[ C + f(\rho_{ij}) + g(\rho_{ij}, \{\alpha_{ij}^{(m)}\}) \right] - A \left( \frac{z_0}{r_{ij}} \right)^6 \right]
\]

where the \( r^{-6} \) term models the attractive London dispersion, the exponential term is designed to capture the registry effect due to overlapping \( pi \) bonds, and \( fc \) is a cutoff function.
This potential (DRIP) only provides the interlayer interactions between graphene layers. So, to perform a realistic simulation, it should be used in combination with an intralayer potential such as \textit{REBO} and \textit{Tersoff}. To keep the intralayer interactions unaffected, we should avoid applying DRIP to contribute energy to intralayer interactions. This can be achieved by assigning different molecular IDs to atoms in different layers, and DRIP is implemented such that only atoms with different molecular ID can interact with each other. For this purpose, \textit{atom style} “molecular” or “full” has to be used.

On the other way around, \textit{REBO} (Tersoff or any other potential used to provide the intralayer interactions) should not interfere with the interlayer interactions described by DRIP. This is typically automatically achieved using the commands provided in the \textit{Examples} section above, since the cutoff distance for carbon-carbon interaction in the intralayer potentials (e.g. 2 Angstrom for \textit{REBO}) is much smaller than the equilibrium layer distance of graphene layers (about 3.4 Angstrom). If you want, you can enforce this by assigning different element types to atoms in different layers, and apply an intralayer potential to one atom type. See \textit{pair_hybrid} for details.

The \textit{pair_coeff} command for DRIP takes \(4+N\) arguments, where \(N\) is the number of LAMMPS atom types. The first three arguments must be fixed to be \(* * \text{drip}\), the fourth argument is the path to the DRIP parameter file, and the remaining \(N\) arguments specifying the mapping between element in the parameter file and atom types. For example, if your LAMMPS simulation has 3 atom types and you want all of them to be C, you would use the following \textit{pair_coeff} command:

\begin{verbatim}
pair_coeff * * drip C.drip C C C
\end{verbatim}

If a mapping value is specified as NULL, the mapping is not performed. This could be useful when DRIP is used to model part of the system where other element exists. Suppose you have a hydrocarbon system, with C of atom type 1 and H of atom type 2, you can use the following command to inform DRIP not to model H atoms:

\begin{verbatim}
pair_style hybrid/overlay drip rebo
pair_coeff * * drip C.drip C NULL
pair_coeff * * rebo CH.airebo C H
\end{verbatim}

\textbf{Note:} The potential parameters developed in \textit{(Wen)} are provided with LAMMPS (see the “potentials” directory). Besides those in \textit{Wen}, an additional parameter “normal_cutoff”, specific to the LAMMPS implementation, is used to find the three nearest neighbors of an atom to construct the normal.

\section*{19.83.4 Mixing, shift, table, tail correction, restart, rRESPA info}

This pair style does not support the \textit{pair_modify mix}, shift, table, and tail options.

This pair style does not write their information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the \textit{pair_style} and \textit{pair_coeff} commands in an input script that reads a restart file.

19.83. \textit{pair_style} drift command 1977
19.83.5 Restrictions

This pair style is part of the INTERLAYER package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This pair style requires the newton setting to be “on” for pair interactions.

The C.drip parameter file provided with LAMMPS (see the “potentials” directory) is parameterized for metal units. You can use the DRIP potential with any LAMMPS units, but you would need to create your own custom parameter file with coefficients listed in the appropriate units, if your simulation does not use “metal” units.

pair_style dsmc max_cell_size seed weighting Tref Nrecompute Nsample

• max_cell_size = global maximum cell size for DSMC interactions (distance units)
• seed = random # seed (positive integer)
• weighting = macroparticle weighting
• Tref = reference temperature (temperature units)
• Nrecompute = re-compute v*sigma_max every this many timesteps (timesteps)
• Nsample = sample this many times in recomputing v*sigma_max

19.84.2 Examples

pair_style dsmc 2.5 34387 10 1.0 100 20
pair_coeff * * 1.0
pair_coeff 1 1 1.0
19.84.3 Description

Style *dsmc* computes collisions between pairs of particles for a direct simulation Monte Carlo (DSMC) model following the exposition in *(Bird)*. Each collision resets the velocities of the two particles involved. The number of pairwise collisions for each pair or particle types and the length scale within which they occur are determined by the parameters of the pair_style and pair_coeff commands.

Stochastic collisions are performed using the variable hard sphere (VHS) approach, with the user-defined *max_cell_size* value used as the maximum DSMC cell size, and reference cross-sections for collisions given using the pair_coeff command.

There is no pairwise energy or virial contributions associated with this pair style.

The following coefficient must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands:

- sigma (area units, i.e. distance-squared)

The global DSMC *max_cell_size* determines the maximum cell length used in the DSMC calculation. A structured mesh is overlayed on the simulation box such that an integer number of cells are created in each direction for each processor’s sub-domain. Cell lengths are adjusted up to the user-specified maximum cell size.

To perform a DSMC simulation with LAMMPS, several additional options should be set in your input script, though LAMMPS does not check for these settings.

Since this pair style does not compute particle forces, you should use the “fix nve/noforce” time integration fix for the DSMC particles, e.g.

```
fix 1 all nve/noforce
```

This pair style assumes that all particles will communicated to neighboring processors every timestep as they move. This makes it possible to perform all collisions between pairs of particles that are on the same processor. To ensure this occurs, you should use these commands:

```
neighbor 0.0 bin
neigh_modify every 1 delay 0 check no
atom_modify sort 0 0.0
communicate single cutoff 0.0
```

These commands ensure that LAMMPS communicates particles to neighboring processors every timestep and that no ghost atoms are created. The output statistics for a simulation run should indicate there are no ghost particles or neighbors.

In order to get correct DSMC collision statistics, users should specify a Gaussian velocity distribution when populating the simulation domain. Note that the default velocity distribution is uniform, which will not give good DSMC collision rates. Specify “dist gaussian” when using the velocity command as in the following:

```
velocity all create 594.6 87287 loop geom dist gaussian
```
19.84.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

This pair style does not support the pair_modify shift option for the energy of the pair interaction.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file. Note that the user-specified random number seed is stored in the restart file, so when a simulation is restarted, each processor will re-initialize its random number generator the same way it did initially. This means the random forces will be random, but will not be the same as they would have been if the original simulation had continued past the restart time.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

19.84.5 Restrictions

This style is part of the MC package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

```

Used in example input script:

```
examples/PACKAGES/e3b/in.e3b-tip4p2005
```

### 19.85.3 Description

The \( e3b \) style computes an "explicit three-body" (E3B) potential for water (Kumar 2008).

\[
E = E_2 \sum_{i,j} e^{-k_2 r_{ij}} + E_A \sum_{i,j,k} f(r_{ij}) f(r_{kl}) + E_B \sum_{i,j,k} f(r_{ij}) f(r_{kl}) + E_C \sum_{i,j,k} f(r_{ij}) f(r_{kl})
\]

\[
f(r) = e^{-k_3 r} s(r)
\]

\[
s(r) = \begin{cases} 
  1 & r < R_s \\
  \frac{(R_f - r)^2 (R_f - 3R_s + 2r)}{(R_f - R_s)^3} & R_s \leq r \leq R_f \\
  0 & r > R_f
\end{cases}
\]

This potential was developed as a water model that includes the three-body cooperativity of hydrogen bonding explicitly. To use it in this way, it must be applied in conjunction with a conventional two-body water model, through pair style \textit{hybrid/overlay}. The three-body interactions are split into three types: A, B, and C. Type A corresponds to anti-cooperative double hydrogen bond donor interactions. Type B corresponds to the cooperative interaction of molecules that both donate and accept a hydrogen bond. Type C corresponds to anti-cooperative double hydrogen bond acceptor interactions. The three-body interactions are smoothly cutoff by the switching function \( s(r) \) between \( R_s \) and \( R_{c3} \). The two-body interactions are designed to correct for the effective many-body interactions implicitly included in the conventional two-body potential. The two-body interactions are cut off sharply at \( R_{c2} \), because \( K_3 \) is typically significantly smaller than \( K_2 \). See (Kumar 2008) for more details.
Only a single `pair_coeff` command is used with the `e3b` style and the first two arguments must be `* *`. The oxygen atom type for the pair style is passed as the only argument to the `pair_style` command, not in the `pair_coeff` command. The hydrogen atom type is inferred from the ordering of the atoms.

**Note:** Every atom of type Otype must be part of a water molecule. Each water molecule must have consecutive IDs with the oxygen first. This pair style does not test that this criteria is met.

The `pair_coeff` command must have at least one keyword/value pair, as described above. The `preset` keyword sets the potential parameters to the values used in (Tainter 2011) or (Tainter 2015). To use the water models defined in those references, the `e3b` style should always be used in conjunction with an `lj/cut/tip4p/long` style through `pair_style hybrid/overlay`, as demonstrated in the second example above. The `preset 2011` option should be used with the TIP4P water model. The `preset 2015` option should be used with the TIP4P/2005 water model. If the `preset` keyword is used, no other keyword is needed. Changes to the preset parameters can be made by specifying the `preset` keyword followed by the specific parameter to change, like `Ea`. Note that the other keywords must come after `preset` in the `pair_style` command. The `e3b` style can also be used to implement any three-body potential of the same form by specifying all the keywords except `neigh`: `Ea`, `Eb`, `Ec`, `E2`, `K3`, `K2`, `Rc3`, `Rc2`, `Rs`, and `bondL`. The keyword `bondL` specifies the intramolecular OH bond length of the water model being used. This is needed to include H atoms that are within the cutoff even when the attached oxygen atom is not.

This pair style allocates arrays sized according to the number of pairwise interactions within Rc3. To do this it needs an estimate for the number of water molecules within Rc3 of an oxygen atom. This estimate defaults to 10 and can be changed using the `neigh` keyword, which takes an integer as an argument. If the neigh setting is too small, the simulation will fail with the error “neigh is too small”. If the neigh setting is too large, the pair style will use more memory than necessary.

This pair style tallies a breakdown of the total E3B potential energy into sub-categories, which can be accessed via the `compute pair` command as a vector of values of length 4. The 4 values correspond to the terms in the first equation above: the E2 term, the Ea term, the Eb term, and the Ec term.

See the examples/PACKAGES/e3b directory for a complete example script.

### 19.85.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the `pair_modify` shift, table, and tail options.

This pair style does not write its information to binary restart files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

This pair style is incompatible with `respa`.

### 19.85.5 Restrictions

This pair style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This pair style requires the `newton` setting to be “on” for pair interactions.

This pair style requires a fixed number of atoms in the simulation, so it is incompatible with fixes like `fix deposit`. If the number of atoms changes between runs, this pair style must be re-initialized by calling the `pair_style` and `pair_coeffs` commands. This is not a fundamental limitation of the pair style, but the code currently does not support a variable number of atoms.

The `preset` keyword currently only works with real, metal, si, and cgs units.

19.91.3 Description

Style `eam` computes pairwise interactions for metals and metal alloys using embedded-atom method (EAM) potentials (Daw). The total energy $E_i$ of an atom $I$ is given by

$$E_i = F_\alpha \left( \sum_{j \neq I} \rho_\beta(r_{ij}) \right) + \frac{1}{2} \sum_{j \neq I} \phi_{\alpha\beta}(r_{ij})$$

where $F$ is the embedding energy which is a function of the atomic electron density $\rho$, $\phi$ is a pair potential interaction, and $\alpha$ and $\beta$ are the element types of atoms $I$ and $J$. The multi-body nature of the EAM potential is a result of the embedding energy term. Both summations in the formula are over all neighbors $J$ of atom $I$ within the cutoff distance.

The cutoff distance and the tabulated values of the functionals $F$, $\rho$, and $\phi$ are listed in one or more files which are specified by the `pair_coeff` command. These are ASCII text files in a DYNAMO-style format which is described below. DYNAMO was the original serial EAM MD code, written by the EAM originators. Several DYNAMO potential files for different metals are included in the “potentials” directory of the LAMMPS distribution. All of these files are parameterized in terms of LAMMPS metal units.

Note: The `eam` style reads single-element EAM potentials in the DYNAMO `funcfl` format. Either single element or alloy systems can be modeled using multiple `funcfl` files and style `eam`. For the alloy case LAMMPS mixes the single-element potentials to produce alloy potentials, the same way that DYNAMO does. Alternatively, a single DYNAMO `setfl` file or Finnis/Sinclair EAM file can be used by LAMMPS to model alloy systems by invoking the `eam/alloy` or `eam/cd` or `eam/fs` or `eam/he` styles as described below. These files require no mixing since they specify alloy interactions explicitly.

Note: Note that unlike for other potentials, cutoffs for EAM potentials are not set in the `pair_style` or `pair_coeff` command; they are specified in the EAM potential files themselves. Likewise, the EAM potential files list atomic masses; thus you do not need to use the `mass` command to specify them.

There are several WWW sites that distribute and document EAM potentials stored in DYNAMO or other formats:
These potentials should be usable with LAMMPS, though the alternate formats would need to be converted to the
DYNAMO format used by LAMMPS and described on this page. The NIST site is maintained by Chandler Becker
(cbecker at nist.gov) who is good resource for info on interatomic potentials and file formats.

The OpenKIM Project at https://openkim.org/browse/models/by-type provides EAM potentials that can be used di-
rectly in LAMMPS with the kim command interface.

For style eam, potential values are read from a file that is in the DYNAMO single-element funcfl format. If the DY-
NAMO file was created by a Fortran program, it cannot have “D” values in it for exponents. C only recognizes “e” or
“E” for scientific notation.

For style eam a potential file must be assigned to each I,I pair of atom types by using one or more pair_coeff commands,
each with a single argument:
- filename

Thus the following command

```plaintext
pair_coeff *2 1*2 cuu3.eam
```

will read the cuu3 potential file and use the tabulated Cu values for F, phi, rho that it contains for type pairs 1,1 and 2,2
(type pairs 1,2 and 2,1 are ignored). See the pair_coeff doc page for alternate ways to specify the path for the potential
file. In effect, this makes atom types 1 and 2 in LAMMPS be Cu atoms. Different single-element files can be assigned
to different atom types to model an alloy system. The mixing to create alloy potentials for type pairs with I != J is done
automatically the same way that the serial DYNAMO code originally did it; you do not need to specify coefficients for
these type pairs.

Funcfl files in the potentials directory of the LAMMPS distribution have an “.eam” suffix. A DYNAMO single-element
funcfl file is formatted as follows:
- line 1: comment (ignored)
- line 2: atomic number, mass, lattice constant, lattice type (e.g. FCC)
- line 3: Nrho, drho, Nr, dr, cutoff

On line 2, all values but the mass are ignored by LAMMPS. The mass is in mass units, e.g. mass number or grams/mole
for metal units. The cubic lattice constant is in Angstroms. On line 3, Nrho and Nr are the number of tabulated values
in the subsequent arrays, drho and dr are the spacing in density and distance space for the values in those arrays, and
the specified cutoff becomes the pairwise cutoff used by LAMMPS for the potential. The units of dr are Angstroms;
I’m not sure of the units for drho - some measure of electron density.

Following the three header lines are three arrays of tabulated values:
- embedding function F(rho) (Nrho values)
- effective charge function Z(r) (Nr values)
- density function rho(r) (Nr values)

The values for each array can be listed as multiple values per line, so long as each array starts on a new line. For
example, the individual Z(r) values are for r = 0,dr,2*dr, … (Nr-1)*dr.

The units for the embedding function F are eV. The units for the density function rho are the same as for drho (see
above, electron density). The units for the effective charge Z are “atomic charge” or sqrt(Hartree * Bohr-radii). For
two interacting atoms i,j this is used by LAMMPS to compute the pair potential term in the EAM energy expression as 
\[ r \cdot \phi = 27.2 \cdot 0.529 \cdot Z_i \cdot Z_j \]
where 1 Hartree = 27.2 eV and 1 Bohr = 0.529 Angstroms.

Style *eam/alloy* computes pairwise interactions using the same formula as style *eam*. However the associated *pair_coeff* command reads a DYNAMO *setfl* file instead of a *funcfl* file. *Setfl* files can be used to model a single-element or alloy system. In the alloy case, as explained above, *setfl* files contain explicit tabulated values for alloy interactions. Thus they allow more generality than *funcfl* files for modeling alloys.

For style *eam/alloy*, potential values are read from a file that is in the DYNAMO multi-element *setfl* format, except that element names (Ni, Cu, etc) are added to one of the lines in the file. If the DYNAMO file was created by a Fortran program, it cannot have “D” values in it for exponents. C only recognizes “e” or “E” for scientific notation.

Only a single *pair_coeff* command is used with the *eam/alloy* style which specifies a DYNAMO *setfl* file, which contains information for M elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the *pair_coeff* command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of *setfl* elements to atom types

As an example, the potentials/NiAlH_jea.eam.alloy file is a *setfl* file which has tabulated EAM values for 3 elements and their alloy interactions: Ni, Al, and H. See the *pair_coeff* doc page for alternate ways to specify the path for the potential file. If your LAMMPS simulation has 4 atom types and you want the first 3 to be Ni, and the fourth to be Al, you would use the following *pair_coeff* command:

```
pair_coeff * * NiAlH_jea.eam.alloy Ni Ni Ni Al
```

The first 2 arguments must be ** so as to span all LAMMPS atom types. The first three Ni arguments map LAMMPS atom types 1,2,3 to the Ni element in the *setfl* file. The final Al argument maps LAMMPS atom type 4 to the Al element in the *setfl* file. Note that there is no requirement that your simulation use all the elements specified by the *setfl* file.

If a mapping value is specified as NULL, the mapping is not performed. This can be used when an *eam/alloy* potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

*Setfl* files in the *potentials* directory of the LAMMPS distribution have an “.eam.alloy” suffix. A DYNAMO multi-element *setfl* file is formatted as follows:

- lines 1,2,3 = comments (ignored)
- line 4: Nelements Element1 Element2 … ElementN
- line 5: Nrho, drho, Nr, dr, cutoff

In a DYNAMO *setfl* file, line 4 only lists Nelements = the # of elements in the *setfl* file. For LAMMPS, the element name (Ni, Cu, etc) of each element must be added to the line, in the order the elements appear in the file.

The meaning and units of the values in line 5 is the same as for the *funcfl* file described above. Note that the cutoff (in Angstroms) is a global value, valid for all pairwise interactions for all element pairings.

Following the 5 header lines are Nelements sections, one for each element, each with the following format:

- line 1 = atomic number, mass, lattice constant, lattice type (e.g. FCC)
- embedding function F(rho) (Nrho values)
- density function rho(r) (Nr values)
As with the *funcfl* files, only the mass (in mass units, e.g. mass number or grams/mole for metal units) is used by LAMMPS from the first line. The cubic lattice constant is in Angstroms. The F and rho arrays are unique to a single element and have the same format and units as in a *funcfl* file.

Following the Nelements sections, Nr values for each pair potential phi(r) array are listed for all i,j element pairs in the same format as other arrays. Since these interactions are symmetric (i,j = j,i) only phi arrays with i >= j are listed, in the following order: i,j = (1,1), (2,1), (2,2), (3,1), (3,2), (3,3), (4,1), ..., (Nelements, Nelements). Unlike the effective charge array Z(r) in *funcfl* files, the tabulated values for each phi function are listed in *setfl* files directly as r*phi (in units of eV-Angstroms), since they are for atom pairs.

Style *eam/cd* is similar to the *eam/alloy* style, except that it computes alloy pairwise interactions using the concentration-dependent embedded-atom method (CD-EAM). This model can reproduce the enthalpy of mixing of alloys over the full composition range, as described in (Stukowski). Style *eam/cd/old* is an older, slightly different and slower two-site formulation of the model (Caro).

The pair_coeff command is specified the same as for the *eam/alloy* style. However the DYNAMO *setfl* file must have two lines added to it, at the end of the file:

- line 1: Comment line (ignored)
- line 2: N Coefficient0 Coefficient1 ... CoefficientN

The last line begins with the degree N of the polynomial function h(x) that modifies the cross interaction between A and B elements. Then N+1 coefficients for the terms of the polynomial are then listed.

Modified EAM *setfl* files used with the *eam/cd* style must contain exactly two elements, i.e. in the current implementation the *eam/cd* style only supports binary alloys. The first and second elements in the input EAM file are always taken as the A and B species.

CD-EAM files in the *potentials* directory of the LAMMPS distribution have a “.cdeam” suffix.

Style *eam/fs* computes pairwise interactions for metals and metal alloys using a generalized form of EAM potentials due to Finnis and Sinclair (Finnis). Style *eam/he* is similar to *eam/fs* except that it allows for negative electron density in order to capture the behavior of helium in metals (Zhou6).

The total energy $E_i$ of an atom I is given by

$$E_i = F_\alpha \left( \sum_{j \neq i} \rho_{\alpha\beta}(r_{ij}) \right) + \frac{1}{2} \sum_{j \neq i} \phi_{\alpha\beta}(r_{ij})$$

where $\rho_{\alpha\beta}$ refers to the density contributed by a neighbor atom J of element $\beta$ at the site of atom I of element $\alpha$. This has the same form as the EAM formula above, except that rho is now a functional specific to the elements of both atoms I and J, so that different elements can contribute differently to the total electron density at an atomic site depending on the identity of the element at that atomic site.

The associated pair_coeff command for style *eam/fs* or *eam/he* reads a DYNAMO *setfl* file that has been extended to include additional $\rho_{\alpha\beta}$ arrays of tabulated values. A discussion of how FS EAM differs from conventional EAM alloy potentials is given in (Ackland1). An example of such a potential is the same author’s Fe-P FS potential (Ackland2).

Note that while FS potentials always specify the embedding energy with a square root dependence on the total density, the implementation in LAMMPS does not require that; the user can tabulate any functional form desired in the FS potential files.

For style *eam/fs* and *eam/he* the form of the pair_coeff command is exactly the same as for style *eam/alloy*, e.g.

```
pair_coeff * * NiAlH_jea.eam.fs Ni Ni Ni Al
```

19.91. pair_style eam/he command 1987
with N additional arguments after the filename, where N is the number of LAMMPS atom types. See the \textit{pair\_coeff} doc page for alternate ways to specify the path for the potential file. The N values determine the mapping of LAMMPS atom types to EAM elements in the file, as described above for style \textit{eam/alloy}. As with \textit{eam/alloy}, if a mapping value is NULL, the mapping is not performed. This can be used when an \textit{eam/fs} or \textit{eam/he} potential is used as part of a \textit{hybrid} pair style. The NULL values are used as placeholders for atom types that will be used with other potentials.

FS EAM and HE EAM files include more information than the DYNAMO \textit{setfl} format files read by \textit{eam/alloy}, in that i,j density functionals for all pairs of elements are included as needed by the Finnis/Sinclair formulation of the EAM.

FS EAM files in the \textit{potentials} directory of the LAMMPS distribution have an “.eam.fs” suffix. They are formatted as follows:

- lines 1,2,3 = comments (ignored)
- line 4: Nelements Element1 Element2 … ElementN
- line 5: Nrho, drho, Nr, dr, cutoff

The 5-line header section is identical to an EAM \textit{setfl} file.

Following the header are Nelements sections, one for each element $\beta$, each with the following format:

- line 1 = atomic number, mass, lattice constant, lattice type (e.g. FCC)
- embedding function $F(\rho)$ (Nrho values)
- density function $\rho_{1\beta}(r)$ for element $\beta$ at element 1 (Nr values)
- density function $\rho_{2\beta}(r)$ for element $\beta$ at element 2
- …
- density function $\rho_{N\beta\beta}(r)$ for element $\beta$ at element $N_{elem}$

The units of these quantities in line 1 are the same as for \textit{setfl} files. Note that the $\rho(\rho)$ arrays in Finnis/Sinclair can be asymmetric ($\rho_{\alpha \beta}(r) \neq \rho_{\beta \alpha}(r)$) so there are Nelements$^2$2 of them listed in the file.

Following the Nelements sections, Nr values for each pair potential $\phi(r)$ array are listed in the same manner ($r*\phi$, units of eV-Angstroms) as in EAM \textit{setfl} files. Note that in Finnis/Sinclair, the $\phi(r)$ arrays are still symmetric, so only $\phi$ arrays for $i \geq j$ are listed.

HE EAM files in the \textit{potentials} directory of the LAMMPS distribution have an “.eam.he” suffix. They are formatted as follows:

- lines 1,2,3 = comments (ignored)
- line 4: Nelements Element1 Element2 … ElementN
- line 5: Nrho, drho, Nr, dr, cutoff, rhomax

The 5-line header section is identical to an FS EAM file except that line 5 lists an additional value, rhomax. Unlike in FS EAM files where embedding energies $F(\rho)$ are always defined between $\rho = 0$ and $\rho = (Nrho - 1)drho$, $F(\rho)$ in HE EAM files are defined between $\rho = \rho_{min}$ and $\rho = \rho_{max}$. Since $drho = (rhomax - \rho_{min})/(Nrho - 1)$, $\rho_{min} = \rho_{rhomax} - (Nrho - 1)drho$. The embedding energies $F(\rho)$ are listed for $\rho = \rho_{min}$, $\rho_{min} + drho$, $\rho_{min} + 2drho$, …, rhomax. This gives users additional flexibility to define a negative \rho_{min} and therefore an embedding energy function that works for both positive and negative electron densities. The format and units of these sections are identical to the FS EAM files (see above).

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Accelerator packages} page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.
These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 19.91.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above with the individual styles. You never need to specify a pair_coeff command with I != J arguments for the eam styles.

This pair style does not support the pair_modify shift, table, and tail options.

The eam pair styles do not write their information to binary restart files, since it is stored in tabulated potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

The eam pair styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

### 19.91.5 Restrictions

All of these styles are part of the MANYBODY package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

19.92 pair_style edip command

Accelerator Variants: edip/omp

19.93 pair_style edip/multi command

19.93.1 Syntax

```
pair_style edip
```

- style = edip or edip/multi

19.93.2 Examples

```
pair_style edip
pair_coeff * * Si.edip Si
```

19.93.3 Description

The edip and edip/multi styles compute a 3-body EDIP potential which is popular for modeling silicon materials where it can have advantages over other models such as the Stillinger-Weber or Tersoff potentials. The edip style has been programmed for single element potentials, while edip/multi supports multi-element EDIP runs.

In EDIP, the energy $E$ of a system of atoms is

$$E = \sum_{j \neq i} \phi_2(R_{ij}, Z_i) + \sum_{j \neq i} \sum_{k > j} \phi_3(R_{ij}, R_{ik}, Z_i)$$

$$\phi_2(r, Z) = A \left[ \left( \frac{B}{r} \right)^{\rho} - e^{-\beta Z^2} \right] e^{\exp\left( \frac{\sigma}{r - a} \right)}$$

$$\phi_3(R_{ij}, R_{ik}, Z_i) = \exp\left( \frac{\gamma}{R_{ij} - a} \right) e^{\exp\left( \frac{\gamma}{R_{ik} - a} \right)} h(cos\theta_{ijk}, Z_i)$$

$$Z_i = \sum_{m \neq i} f(R_{im})$$

$$f(r) = \begin{cases} 
1 & r < c \\
\exp\left( \frac{\alpha}{1 - x} \right) & c < r < a \\
0 & r > a 
\end{cases}$$

$$h(l, Z) = \lambda \left[ (1 - e^{-Q(Z)(l + \tau(Z))^2}) + \eta Q(Z)(l + \tau(Z))^2 \right]$$

$$Q(Z) = Q_0 e^{-\mu Z}$$

$$\tau(Z) = u_1 + u_2 (u_3 e^{-u_4 Z} - e^{-2u_4 Z})$$

where $\phi_2$ is a two-body term and $\phi_3$ is a three-body term. The summations in the formula are over all neighbors $J$ and $K$ of atom $I$ within a cutoff distance $= a$. Both terms depend on the local environment of atom $I$ through its effective coordination number defined by $Z$, which is unity for a cutoff distance $< c$ and gently goes to 0 at distance $= a$.

Only a single pair_coeff command is used with the edip style which specifies a EDIP potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where $N$ is the number of LAMMPS atom types:

- filename
- N element names = mapping of EDIP elements to atom types
See the `pair_coeff` page for alternate ways to specify the path for the potential file.

As an example, imagine a file Si.edip has EDIP values for Si.

EDIP files in the `potentials` directory of the LAMMPS distribution have a “.edip” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to the two-body and three-body coefficients in the formula above:

- element 1 (the center atom in a 3-body interaction)
- element 2
- element 3
- A (energy units)
- B (distance units)
- cutoffA (distance units)
- cutoffC (distance units)
- $\alpha$
- $\beta$
- $\eta$
- $\gamma$ (distance units)
- $\lambda$ (energy units)
- $\mu$
- $\tau$
- $\sigma$ (distance units)
- Q0
- u1
- u2
- u3
- u4

The A, B, beta, sigma parameters are used only for two-body interactions. The eta, gamma, lambda, mu, Q0 and all u1 to u4 parameters are used only for three-body interactions. The alpha and cutoffC parameters are used for the coordination environment function only.

The EDIP potential file must contain entries for all the elements listed in the `pair_coeff` command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCSi, SiCC, CSiSi, CSiC, CCSi, CCC), that specify EDIP parameters for all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.

At the moment, only a single element parameterization is implemented. However, the author is not aware of other multi-element EDIP parameterization. If you know any and you are interest in that, please contact the author of the EDIP package.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages.

19.93. `pair_style edip/multi command`
The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

19.93.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

19.93.5 Restrictions

This pair style can only be used if LAMMPS was built with the MANYBODY package. See the Build package doc page for more info.

This pair style requires the newton setting to be “on” for pair interactions.

The EDIP potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the EDIP potential with any LAMMPS units, but you would need to create your own EDIP potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

```

19.94.3 Description

This pair style contains a LAMMPS implementation of the electron Force Field (eFF) potential currently under development at Caltech, as described in (Jaramillo-Botero). The eFF for Z<6 was first introduced by (Su) in 2007. It has been extended to higher Zs by using effective core potentials (ECPs) that now cover up to second and third row p-block elements of the periodic table.

eFF can be viewed as an approximation to QM wave packet dynamics and Fermionic molecular dynamics, combining the ability of electronic structure methods to describe atomic structure, bonding, and chemistry in materials, and of plasma methods to describe nonequilibrium dynamics of large systems with a large number of highly excited electrons. Yet, eFF relies on a simplification of the electronic wave function in which electrons are described as floating Gaussian wave packets whose position and size respond to the various dynamic forces between interacting classical nuclear particles and spherical Gaussian electron wave packets. The wave function is taken to be a Hartree product of the wave packets. To compensate for the lack of explicit antisymmetry in the resulting wave function, a spin-dependent Pauli potential is included in the Hamiltonian. Substituting this wave function into the time-dependent Schrodinger equation produces equations of motion that correspond - to second order - to classical Hamiltonian relations between electron position and size, and their conjugate momenta. The N-electron wave function is described as a product of one-electron Gaussian functions, whose size is a dynamical variable and whose position is not constrained to a nuclear center. This form allows for straightforward propagation of the wave function, with time, using a simple formulation from which the equations of motion are then integrated with conventional MD algorithms. In addition to this spin-dependent Pauli repulsion potential term between Gaussians, eFF includes the electron kinetic energy from the Gaussians. These two terms are based on first-principles quantum mechanics. On the other hand, nuclei are described as point charges, which interact with other nuclei and electrons through standard electrostatic potential forms.
The full Hamiltonian (shown below), contains then a standard description for electrostatic interactions between a set of delocalized point and Gaussian charges which include, nuclei-nuclei (NN), electron-electron (ee), and nuclei-electron (Ne). Thus, eFF is a mixed QM-classical mechanics method rather than a conventional force field method (in which electron motions are averaged out into ground state nuclear motions, i.e a single electronic state, and particle interactions are described via empirically parameterized interatomic potential functions). This makes eFF uniquely suited to simulate materials over a wide range of temperatures and pressures where electronically excited and ionized states of matter can occur and coexist. Furthermore, the interactions between particles -nuclei and electrons- reduce to the sum of a set of effective pairwise potentials in the eFF formulation. The \texttt{eff/cut} style computes the pairwise Coulomb interactions between nuclei and electrons ($E_{NN}, E_{Ne}, E_{ee}$), and the quantum-derived Pauli ($E_{PR}$) and Kinetic energy interactions potentials between electrons ($E_{KE}$) for a total energy expression given as,

$$U(R, r, s) = E_{NN}(R) + E_{Ne}(R, r, s) + E_{ee}(r, s) + E_{KE}(r, s) + E_{PR}(\uparrow\downarrow, S)$$

The individual terms are defined as follows:

$$E_{KE} = \frac{\hbar^2}{m_e} \sum_i \frac{3}{2s_i^2}$$

$$E_{NN} = \frac{1}{4\pi\varepsilon_0} \sum_{i<j} \frac{Z_i Z_j}{R_{ij}}$$

$$E_{Ne} = -\frac{1}{4\pi\varepsilon_0} \sum_{i,j} \frac{Z_i}{R_{ij}} Erf \left( \frac{\sqrt{2}R_{ij}}{s_j} \right)$$

$$E_{ee} = \frac{1}{4\pi\varepsilon_0} \sum_{i<j} \frac{1}{r_{ij}} Erf \left( \frac{\sqrt{2}r_{ij}}{\sqrt{s_i^2 + s_j^2}} \right)$$

$$E_{Pauli} = \sum_{\sigma_i=\sigma_j} E(\uparrow\uparrow)_{ij} + \sum_{\sigma_i\neq\sigma_j} E(\uparrow\downarrow)_{ij}$$

where, $s_i$ correspond to the electron sizes, the sigmas $i$‘s to the fixed spins of the electrons, $Z_i$ to the charges on the nuclei, $R_{ij}$ to the distances between the nuclei or the nuclei and electrons, and $r_{ij}$ to the distances between electrons. For additional details see (Jaramillo-Botero).

The overall electrostatics energy is given in Hartree units of energy by default and can be modified by an energy-conversion constant, according to the units chosen (see \textit{electron_units}). The cutoff $R_c$, given in Bohrs (by default), truncates the interaction distance. The recommended cutoff for this pair style should follow the minimum image criterion, i.e. half of the minimum unit cell length.

Style \texttt{eff/long} (not yet available) computes the same interactions as style \texttt{eff/cut} except that an additional damping factor is applied so it can be used in conjunction with the \texttt{kspace_style} command and its \texttt{ewald} or \texttt{pppm} option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

This potential is designed to be used with \texttt{atom_style electron} definitions, in order to handle the description of systems with interacting nuclei and explicit electrons.

The following coefficients must be defined for each pair of atoms types via the \texttt{pair_coeff} command as in the examples above, or in the data file or restart files read by the \texttt{read_data} or \texttt{read_restart} commands, or by mixing as described below:

- cutoff (distance units)

For \texttt{eff/cut}, the cutoff coefficient is optional. If it is not used (as in some of the examples above), the default global value specified in the \texttt{pair_style} command is used.

For \texttt{eff/long} (not yet available) no cutoff will be specified for an individual IJ type pair via the \texttt{pair_coeff} command. All type pairs use the same global cutoff specified in the \texttt{pair_style} command.
The `limit/eradius` and `pressure/evirials` keywords are optional. Neither or both must be specified. If not specified they are unset.

The `limit/eradius` keyword is used to restrain electron size from becoming excessively diffuse at very high temperatures were the Gaussian wave packet representation breaks down, and from expanding as free particles to infinite size. If unset, electron radius is free to increase without bounds. If set, a restraining harmonic potential of the form $E = \frac{1}{2} k_s s^2$ for $s > \frac{L_{\text{box}}}{2}$, where $k_s = 1$ Hartrees/Bohr$^2$, is applied on the electron radius.

The `pressure/evirials` keyword is used to control between two types of pressure computation: if unset, the computed pressure does not include the electronic radial virials contributions to the total pressure (scalar or tensor). If set, the computed pressure will include the electronic radial virial contributions to the total pressure (scalar and tensor).

The `ecp` keyword is used to associate an ECP representation for a particular atom type. The ECP captures the orbital overlap between a core pseudo particle and valence electrons within the Pauli repulsion. A list of type:element-symbol pairs may be provided for all ECP representations, after the “ecp” keyword.

**Note:** Default ECP parameters are provided for C, N, O, Al, and Si. Users can modify these using the `pair_coeff` command as exemplified above. For this, the User must distinguish between two different functional forms supported, one that captures the orbital overlap assuming the s-type core interacts with an s-like valence electron (s-s) and another that assumes the interaction is s-p. For systems that exhibit significant p-character (e.g., C, N, O) the s-p form is recommended. The “s” ECP form requires 3 parameters and the “p” 5 parameters.

**Note:** there are two different pressures that can be reported for eFF when defining this pair_style, one (default) that considers electrons do not contribute radial virial components (i.e. electrons treated as incompressible ’rigid’ spheres) and one that does. The radial electronic contributions to the virials are only tallied if the flexible pressure option is set, and this will affect both global and per-atom quantities. In principle, the true pressure of a system is somewhere in between the rigid and the flexible eFF pressures, but, for most cases, the difference between these two pressures will not be significant over long-term averaged runs (i.e. even though the energy partitioning changes, the total energy remains similar).

**Note:** This implementation of eFF gives a reasonably accurate description for systems containing nuclei from $Z = 1$-6 in “all electron” representations. For systems with increasingly non-spherical electrons, Users should use the ECP representations. ECPs are now supported and validated for most of the second and third row elements of the p-block. Predefined parameters are provided for C, N, O, Al, and Si. The ECP captures the orbital overlap between the core and valence electrons (i.e. Pauli repulsion) with one of the functional forms:

\[
E_{\text{Pauli(ECP}_s)} = p_1 \exp \left( -\frac{p_2 r^2}{p_3 + s^2} \right)
\]

\[
E_{\text{Pauli(ECP}_p)} = p_1 \left( \frac{2}{p_2/s + s/p_2} \right) (r - p_3 s)^2 \exp \left[-\frac{p_1 (r - p_3 s)^2}{p_5 + s^2}\right]
\]

Where the first form correspond to core interactions with s-type valence electrons and the second to core interactions with p-type valence electrons.

The current version adds full support for models with fixed-core and ECP definitions. to enable larger timesteps (i.e. by avoiding the high frequency vibrational modes -translational and radial- of the 2 s electrons), and in the ECP case to reduce the increased orbital complexity in higher Z elements (up to Z<18). A fixed-core should be defined with a mass that includes the corresponding nuclear mass plus the 2 s electrons in atomic mass units (2x5.4857990943e-4), and a radius equivalent to that of minimized 1s electrons (see examples under /examples/PACKAGES/eff/fixed-core). An
pseudo-core should be described with a mass that includes the corresponding nuclear mass, plus all the core electrons (i.e. no outer shell electrons), and a radius equivalent to that of a corresponding minimized full-electron system. The charge for a pseudo-core atom should be given by the number of outer shell electrons.

In general, eFF excels at computing the properties of materials in extreme conditions and tracing the system dynamics over multi-picosecond timescales; this is particularly relevant where electron excitations can change significantly the nature of bonding in the system. It can capture with surprising accuracy the behavior of such systems because it describes consistently and in an unbiased manner many different kinds of bonds, including covalent, ionic, multicenter, ionic, and plasma, and how they interconvert and/or change when they become excited. eFF also excels in computing the relative thermochemistry of isodemic reactions and conformational changes, where the bonds of the reactants are of the same type as the bonds of the products. eFF assumes that kinetic energy differences dominate the overall exchange energy, which is true when the electrons present are nearly spherical and nodeless and valid for covalent compounds such as dense hydrogen, hydrocarbons, and diamond; alkali metals (e.g. lithium), alkali earth metals (e.g. beryllium) and semimetals such as boron; and various compounds containing ionic and/or multicenter bonds, such as boron dihydride.

19.94.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the cutoff distance for the eff/cut style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

The pair_modify shift option is not relevant for these pair styles.

The eff/long (not yet available) style supports the pair_modify table option for tabulation of the short-range portion of the long-range Coulombic interaction.

These pair styles do not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

These pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

19.94.5 Restrictions

These pair styles will only be enabled if LAMMPS is built with the EFF package. It will only be enabled if LAMMPS was built with that package. See the Build package page for more info.

These pair styles require that particles store electron attributes such as radius, radial velocity, and radial force, as defined by the atom_style. The electron atom style does all of this.

These pair styles require you to use the comm_modify vel yes command so that velocities are stored by ghost atoms.

19.95 pair_style eim command

Accelerator Variants: eim/omp

19.95.1 Syntax

```
pair_style style

• style = eim
```

19.95.2 Examples

```
pair_style eim
pair_coeff * * Na Cl ../potentials/ffield.eim Na Cl
pair_coeff * * Na Cl ffield.eim Na Na Na Cl
pair_coeff * * Na Cl ../potentials/ffield.eim Cl NULL Na
```

19.95.3 Description

Style eim computes pairwise interactions for ionic compounds using embedded-ion method (EIM) potentials (Zhou).

The energy of the system E is given by

\[
E = \frac{1}{2} \sum_{i=1}^{N} \sum_{j=1}^{iN} \phi_{ij} (r_{ij}) + \sum_{i=1}^{N} E_i (q_i, \sigma_i)
\]

The first term is a double pairwise sum over the J neighbors of all I atoms, where \( \phi_{ij} \) is a pair potential. The second term sums over the embedding energy \( E_i \) of atom I, which is a function of its charge \( q_i \) and the electrical potential \( \sigma_i \) at its location. \( E_i, q_i, \) and \( \sigma_i \) are calculated as

\[
q_i = \sum_{j=1}^{iN} \eta_{ij} (r_{ij})
\]

\[
\sigma_i = \sum_{j=1}^{iN} q_j \cdot \psi_{ij} (r_{ij})
\]

\[
E_i (q_i, \sigma_i) = \frac{1}{2} \cdot q_i \cdot \sigma_i
\]
where $\eta_{ij}$ is a pairwise function describing electron flow from atom I to atom J, and $\psi_{ij}$ is another pairwise function. The multi-body nature of the EIM potential is a result of the embedding energy term. A complete list of all the pair functions used in EIM is summarized below

$$
\phi_{ij}(r) = \left\{ \begin{array}{lcl}
\frac{E_{b,ij}r_{ij}}{r_{ij}} \exp \left( -\frac{r - r_{c,ij}}{r_{c,ij}} \right) - \frac{E_{b,ij}r_{ij}}{r_{ij}} \exp \left( -\frac{r - r_{c,ij}}{r_{c,ij}} \right) 
\end{array} \right. f_c(r, r_{c,ij}, r_{c,\phi,ij}), \quad p_{ij} = 1
$$

$$
\eta_{ij} = A_{\eta,ij} (\chi_j - \chi_i) f_c(r, r_s,\eta,ij, r_{c,\eta,ij})
$$

$$
\psi_{ij}(r) = A_{\psi,ij} \exp \left( -\zeta_{ij} r \right) f_c(r, r_s,\psi,ij, r_{c,\psi,ij})
$$

$$
f_c(r, r_p, r_c) = 0.510204 \cdot \text{erfc} \left[ \frac{1.64498 \left( 2r - r_p - r_c \right)}{r_c - r_p} \right] - 0.010204
$$

Here $E_b, r_c, r_p, c, \phi, \alpha, \beta, A_1(\psi), \zeta, r(s, \psi), r(c, \psi), A_1(\eta), r(s, \eta), r(c, \eta), \chi_i$, and pair function type $p$ are parameters, with subscripts $ij$ indicating the two species of atoms in the atomic pair.

**Note:** Even though the EIM potential is treating atoms as charged ions, you should not use a LAMMPS `atom_style` that stores a charge on each atom and thus requires you to assign a charge to each atom, e.g. the charge or full atom styles. This is because the EIM potential infers the charge on an atom from the equation above for $q_i$; you do not assign charges explicitly.

All the EIM parameters are listed in a potential file which is specified by the `pair_coeff` command. This is an ASCII text file in a format described below. The “ffield.eim” file included in the “potentials” directory of the LAMMPS distribution currently includes nine elements Li, Na, K, Rb, Cs, F, Cl, Br, and I. A system with any combination of these elements can be modeled. This file is parameterized in terms of LAMMPS metal units.

Note that unlike other potentials, cutoffs for EIM potentials are not set in the pair_style or pair_coeff command; they are specified in the EIM potential file itself. Likewise, the EIM potential file lists atomic masses; thus you do not need to use the mass command to specify them.

Only a single pair_coeff command is used with the `eim` style which specifies an EIM potential file and the element(s) to extract information for. The EIM elements are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where N is the number of LAMMPS atom types:

- Elem1, Elem2, ...
- EIM potential file
- N element names = mapping of EIM elements to atom types

See the `pair_coeff` page for alternate ways to specify the path for the potential file.

As an example like one of those above, suppose you want to model a system with Na and Cl atoms. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Na, and the fourth to be Cl, you would use the following pair_coeff command:

```
pair_coeff * * Na Cl ffield.eim Na Na Na Cl
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The filename is the EIM potential file. The Na and Cl arguments (before the file name) are the two elements for which info will be extracted from the potential file. The first three trailing Na arguments map LAMMPS atom types 1,2,3 to the EIM Na element. The final Cl argument maps LAMMPS atom type 4 to the EIM Cl element.

If a mapping value is specified as NULL, the mapping is not performed. This can be used when an `eim` potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.
The ffield.eim file in the potentials directory of the LAMMPS distribution is formatted as follows:

Lines starting with # are comments and are ignored by LAMMPS. Lines starting with “global:” include three global values. The first value divides the cations from anions, i.e., any elements with electronegativity above this value are viewed as anions, and any elements with electronegativity below this value are viewed as cations. The second and third values are related to the cutoff function - i.e. the 0.510204, 1.64498, and 0.010204 shown in the above equation can be derived from these values.

Lines starting with “element:” are formatted as follows: name of element, atomic number, atomic mass, electronic negativity, atomic radius (LAMMPS ignores it), ionic radius (LAMMPS ignores it), cohesive energy (LAMMPS ignores it), and q0 (must be 0).

Lines starting with “pair:” are entered as: element 1, element 2, r_(c,phi), r_(c,phi) (redundant for historical reasons), E_b, r_e, alpha, beta, r_(c,eta), A_(eta), r_(s,eta), r_(c,psi), A_(psi), zeta, r_(s,psi), and p.

The lines in the file can be in any order; LAMMPS extracts the info it needs.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

19.95.4 Restrictions

This style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package.

pair_coeff * * exp6.params 1fluid 1fluid polynomial filename 10.0
```

19.96.3 Description

Style `exp6/rx` is used in reaction DPD simulations, where the coarse-grained (CG) particles are composed of `m` species whose reaction rate kinetics are determined from a set of `n` reaction rate equations through the `fix rx` command. The species of one CG particle can interact with a species in a neighboring CG particle through a site-site interaction potential model. The `exp6/rx` style computes an exponential-6 potential given by

\[
U_{ij}(r) = \frac{\epsilon}{\alpha - 6} \{6 \exp[\alpha(1 - \frac{r_{ij}}{R_m})] - \alpha(\frac{R_m}{r_{ij}})^6\}
\]

where the \( \epsilon \) parameter determines the depth of the potential minimum located at \( R_m \), and \( \alpha \) determines the softness of the repulsion.

The coefficients must be defined for each species in a given particle type via the `pair_coeff` command as in the examples above, where the first argument is the filename that includes the exponential-6 parameters for each species. The file includes the species tag followed by the \( \alpha, \epsilon \) and \( R_m \) parameters. The format of the file is described below.

The second and third arguments specify the site-site interaction potential between two species contained within two different particles. The species tags must either correspond to the species defined in the reaction kinetics files specified with the `fix rx` command or they must correspond to the tag “1fluid”, signifying interaction with a product species mixture determined through a one-fluid approximation. The interaction potential is weighted by the geometric average of either the mole fraction concentrations or the number of molecules associated with the interacting coarse-grained particles (see the `fractional` or `molecular` weighting pair style options). The coarse-grained potential is stored before and after the reaction kinetics solver is applied, where the difference is defined to be the internal chemical energy (uChem).

The fourth argument specifies the type of scaling that will be used to scale the EXP-6 parameters as reactions occur. Currently, there are three scaling options: `exponent`, `polynomial` and `none`. 
Exponent scaling requires two additional arguments for scaling the $R_m$ and $\epsilon$ parameters, respectively. The scaling factor is computed by $\phi^\text{exponent}$, where $\phi$ is the number of molecules represented by the coarse-grain particle and exponent is specified as a pair coefficient argument for $R_m$ and $\epsilon$, respectively. The $R_m$ and $\epsilon$ parameters are multiplied by the scaling factor to give the scaled interaction parameters for the CG particle.

Polynomial scaling requires a filename to be specified as a pair coeff argument. The file contains the coefficients to a fifth order polynomial for the $\alpha$, $\epsilon$ and $R_m$ parameters that depend upon $\phi$ (the number of molecules represented by the CG particle). The format of a polynomial file is provided below.

The none option to the scaling does not have any additional pair coeff arguments. This is equivalent to specifying the exponent option with $R_m$ and $\epsilon$ exponents of 0.0 and 0.0, respectively.

The final argument specifies the interaction cutoff (optional).

The format of a tabulated file is as follows (without the parenthesized comments):

```
# exponential-6 parameters for various species (one or more comment or blank lines)
h2o  exp6  11.00  0.02  3.50  (species, exp6, alpha, Rm, epsilon)
n2o  exp6  13.60  0.01  3.70
... co2  exp6  13.00  0.03  3.20
```

The format of the polynomial scaling file as follows (without the parenthesized comments):

```
# POLYNOMIAL FILE (one or more comment or blank lines)
# General Functional Form:
# $A \times \phi^5 + B \times \phi^4 + C \times \phi^3 + D \times \phi^2 + E \times \phi + F$

# Parameter  A   B    C    D    E    F
alpha  0.0000 0.0000 0.0000 0.04955 -0.73804 13.63201
epsilon 0.0000 0.00478 -0.06283 0.24486 -0.33737 2.60097
rm 0.0001 -0.00118 -0.00253 0.05812 -0.00509 1.50106
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections.

Following a blank line, the next $N$ lines list the species and their corresponding parameters. The first argument is the species tag, the second argument is the exp6 tag, the third argument is the $\alpha$ parameter (energy units), the fourth argument is the $\epsilon$ parameter (energy-distance$^6$ units), and the fifth argument is the $R_m$ parameter (distance units). If a species tag of “1fluid” is listed as a pair coefficient, a one-fluid approximation is specified where a concentration-dependent combination of the parameters is computed through the following equations:

$$R_m^3 = \sum_a \sum_b x_a x_b R_{m,ab}^3$$

$$\epsilon = \frac{1}{R_m^3} \sum_a \sum_b x_a x_b \epsilon_{ab} R_{m,ab}^3$$

$$\alpha = \frac{1}{\epsilon R_m^3} \sum_a \sum_b x_a x_b \alpha_{ab} \epsilon_{ab} R_{m,ab}^3$$
where
\[
\begin{align*}
\epsilon_{ab} &= \sqrt{\epsilon_a \epsilon_b} \\
R_{m,ab} &= \frac{R_{m,a} + R_{m,b}}{2} \\
\alpha_{ab} &= \sqrt{\alpha_a \alpha_b}
\end{align*}
\]
and \(x_a\) and \(x_b\) are the mole fractions of \(a\) and \(b\), respectively, which comprise the gas mixture.

### 19.96.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

This style does not support the `pair_modify shift` option for the energy of the \(\exp()\) and \(1/r^6\) portion of the pair interaction.

This style does not support the `pair_modify tail` option for adding long-range tail corrections to energy and pressure for the \(A,C\) terms in the pair interaction.

---

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

Example input scripts available: examples/PACKAGES/fep

19.109.3 Description

These pair styles have a soft repulsive core, tunable by a parameter lambda, in order to avoid singularities during free energy calculations when sites are created or annihilated (Beutler). When lambda tends to 0 the pair interaction vanishes with a soft repulsive core. When lambda tends to 1, the pair interaction approaches the normal, non-soft potential. These pair styles are suited for “alchemical” free energy calculations using the fix adapt/fep and compute fep commands.

The lj/cut/soft style and related sub-styles compute the 12-6 Lennard-Jones and Coulomb potentials modified by a soft core, with the functional form

\[ E = \lambda^n 4\epsilon \left[ \frac{1}{\alpha_{\text{LJ}}(1-\lambda)^2 + \left(\frac{r}{\sigma}\right)^6} - \frac{1}{\alpha_{\text{LJ}}(1-\lambda)^2 + \left(\frac{r}{\sigma}\right)^6} \right] \quad r < r_c \]

The lj/class2/soft style is a 9-6 potential with the exponent of the denominator of the first term in brackets taking the value 1.5 instead of 2 (other details differ, see the form of the potential in pair_style lj/class2).

Coulomb interactions can also be damped with a soft core at short distance,

\[ E = \lambda^n \frac{C q_i q_j}{\epsilon \left[ \alpha_{\text{C}}(1-\lambda)^2 + r^2 \right]^{1/2}} \quad r < r_c \]

In the Coulomb part \( C \) is an energy-conversion constant, \( q_i \) and \( q_j \) are the charges on the 2 atoms, and epsilon is the dielectric constant which can be set by the dielectric command.

The coefficient lambda is an activation parameter. When \( \lambda = 1 \) the pair potential is identical to a Lennard-Jones term or a Coulomb term or a combination of both. When \( \lambda = 0 \) the interactions are deactivated. The transition between these two extrema is smoothed by a soft repulsive core in order to avoid singularities in potential energy and forces when sites are created or annihilated and can overlap (Beutler).

The parameters \( n \), \( \alpha_{\text{LJ}} \) and \( \alpha_{\text{C}} \) are set in the pair_style command, before the cutoffs. Usual choices for the exponent are \( n = 2 \) or \( n = 1 \). For the remaining coefficients \( \alpha_{\text{LJ}} = 0.5 \) and \( \alpha_{\text{C}} = 10 \text{ Å}^2 \) are appropriate choices. Plots of the 12-6 LJ and Coulomb terms are shown below, for lambda ranging from 1 to 0 every 0.1.

![Graph showing pair_style morse/soft command](image)
For the lj/cut/coul/cut/coul/cut/soft or lj/cut/coul/long/soft pair styles, as well as for the equivalent class2 versions, the following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- $\epsilon$ (energy units)
- $\sigma$ (distance units)
- $\lambda$ (activation parameter, between 0 and 1)
- cutoff1 (distance units)
- cutoff2 (distance units)

The latter two coefficients are optional. If not specified, the global LJ and Coulombic cutoffs specified in the `pair_style` command are used. If only one cutoff is specified, it is used as the cutoff for both LJ and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the LJ and Coulombic cutoffs for this type pair. You cannot specify 2 cutoffs for style `lj/cut/soft`, since it has no Coulombic terms. For the `coul/cut/soft` and `coul/long/soft` only lambda and the optional cutoff2 are to be specified.

Style `lj/cut/tip4p/long/soft` implements a soft-core version of the TIP4P water model. The usage of the TIP4P pair style is documented in the `pair_lj` styles. In the soft version the parameters $n$, $\alpha_{LJ}$ and $\alpha_{C}$ are set in the `pair_style` command, after the specific parameters of the TIP4P water model and before the cutoffs. The activation parameter lambda is supplied as an argument of the `pair_coeff` command, after $\epsilon$ and $\sigma$ and before the optional cutoffs.

Style `lj/charmm/coul/long/soft` implements a soft-core version of the modified 12-6 LJ potential used in CHARMM and documented in the `pair_style lj/charmm/coul/long` style. In the soft version the parameters $n$, $\alpha_{LJ}$ and $\alpha_{C}$ are set in the `pair_style` command, before the global cutoffs. The activation parameter lambda is introduced as an argument of the `pair_coeff` command, after $\epsilon$ and $\sigma$ and before the optional eps14 and sigma14.

Style `lj/class2/soft` implements a soft-core version of the 9-6 potential in `pair_style lj/class2`. In the soft version the parameters $n$, $\alpha_{LJ}$ and $\alpha_{C}$ are set in the `pair_style` command, before the global cutoffs. The activation parameter lambda is introduced as an argument of the `pair_coeff` command, after $\epsilon$ and $\sigma$ and before the optional cutoffs.

The `coul/cut/soft`, `coul/long/soft` and `tip4p/long/soft` sub-styles are designed to be combined with other pair potentials via the `pair_style hybrid/overlay` command. This is because they have no repulsive core. Hence, if used by themselves, there will be no repulsion to keep two oppositely charged particles from overlapping each other. In this case, if $\lambda = 1$, a singularity may occur. These sub-styles are suitable to represent charges embedded in the Lennard-Jones radius of another site (for example hydrogen atoms in several water models). The $\lambda$ must be defined for each pair, and `coul/cut/soft` can accept an optional cutoff as the second coefficient.

**Note:** When using the soft-core Coulomb potentials with long-range solvers (`coul/long/soft`, `lj/cut/coul/long/soft`, etc.) in a free energy calculation in which sites holding electrostatic charges are being created or annihilated (using `fix adapt/fep` and `compute fep`) it is important to adapt both the $\lambda$ activation parameter (from 0 to 1, or the reverse)
and the value of the charge (from 0 to its final value, or the reverse). This ensures that long-range electrostatic terms (kspace) are correct. It is not necessary to use soft-core Coulomb potentials if the van der Waals site is present during the free-energy route, thus avoiding overlap of the charges. Examples are provided in the LAMMPS source directory tree, under examples/PACKAGES/fep.

**Note:** To avoid division by zero do not set $\sigma = 0$ in the $lj/cut/soft$ and related styles; use the lambda parameter instead to activate/deactivate interactions, or use $\epsilon = 0$ and $\sigma = 1$. Alternatively, when sites do not interact though the Lennard-Jones term the $coul/long/soft$ or similar sub-style can be used via the `pair_style hybrid/overlay` command.

The `morse/soft` variant modifies the `pair_morse` style at short range to have a soft core. The functional form differs from that of the `lj/soft` styles, and is instead given by:

$$s(\lambda) = (1 - \lambda) / (1 - \lambda_f), \quad B = -2D e^{-2\alpha r_0}(e^{\alpha r_0} - 1)/3$$

$$E = D_0 \left[ e^{-2\alpha(r - r_0)} - 2e^{-\alpha(r - r_0)} \right] + s(\lambda) B e^{-3\alpha(r - r_0)}, \quad \lambda \geq \lambda_f, \quad r < r_c$$

$$E = \left( D_0 \left[ e^{-2\alpha(r - r_0)} - 2e^{-\alpha(r - r_0)} \right] + B e^{-3\alpha(r - r_0)} \right) \left( \frac{\lambda}{\lambda_f} \right)^n, \quad \lambda < \lambda_f, \quad r < r_c$$

The `morse/soft` style requires the following pair coefficients:

- $D_0$ (energy units)
- $\alpha$ (1/distance units)
- $r_0$ (distance units)
- $\lambda$ (unitless, between 0.0 and 1.0)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global morse cutoff is used.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
19.109.4 Mixing, shift, table, tail correction, restart, rRESPA info

The different versions of the \textit{lj/cut/soft} pair styles support mixing. For atom type pairs I and J \( I \neq J \), the \( \epsilon \) and \( \sigma \) coefficients and cutoff distance for these pair styles can be mixed. The default mix value is geometric for 12-6 styles.

The mixing rule for epsilon and sigma for \textit{lj/class2/soft} 9-6 potentials is to use the \textit{sixthpower} formulas. The \textit{pair_modify mix} setting is thus ignored for class2 potentials for \( \epsilon \) and \( \sigma \). However it is still followed for mixing the cutoff distance. See the \textit{pair_modify} command for details.

The \textit{morse/soft} pair style does not support mixing. Thus, coefficients for all LJ pairs must be specified explicitly.

All of the pair styles with soft core support the \textit{pair_modify} \textit{shift} option for the energy of the Lennard-Jones portion of the pair interaction.

The different versions of the \textit{lj/cut/soft} pair styles support the \textit{pair_modify} \textit{tail} option for adding a long-range tail correction to the energy and pressure for the Lennard-Jones portion of the pair interaction.

\textbf{Note:} The analytical form of the tail corrections for energy and pressure used in the \textit{lj/cut/soft} potentials are approximate, being identical to that of the corresponding non-soft potentials scaled by a factor \( \lambda^n \). The errors due to this approximation should be negligible. For example, for a cutoff of 2.5\( \sigma \) this approximation leads to maximum relative errors in tail corrections of the order of 1e-4 for energy and virial \((\alpha_{LJ} = 0.5, n = 2)\). The error vanishes when \( \lambda \) approaches 0 or 1. Note that these are the errors affecting the long-range tail (itself a correction to the interaction energy) which includes other approximations, namely that the system is homogeneous (local density equal the average density) beyond the cutoff.

The \textit{morse/soft} pair style does not support the \textit{pair_modify} \textit{tail} option for adding long-range tail corrections to energy and pressure.

All of these pair styles write information to \textit{binary restart files}, so \textit{pair_style} and \textit{pair_coeff} commands do not need to be specified in an input script that reads a restart file.

19.109.5 Restrictions

The pair styles with soft core are only enabled if LAMMPS was built with the FEP package. The long versions also require the KSPACE package to be installed. The soft \textit{tip4p} versions also require the MOLECULE package to be installed. These styles are only enabled if LAMMPS was built with those packages. See the \textit{Build package} page for more info.

19.109.7 Default

none

19.110 pair_style gauss command

Accelerator Variants: gauss/gpu, gauss/omp

19.111 pair_style gauss/cut command

Accelerator Variants: gauss/cut/omp

19.111.1 Syntax

```
pair_style gauss cutoff
pair_style gauss/cut cutoff
```

- cutoff = global cutoff for Gauss interactions (distance units)

19.111.2 Examples

```
pair_style gauss 12.0
pair_coeff * * 1.0 0.9
pair_coeff 1 4 1.0 0.9 10.0

pair_style gauss/cut 3.5
pair_coeff 1 4 0.2805 1.45 0.112
```

19.111.3 Description

Style `gauss` computes a tethering potential of the form

$$ E = -A \exp(-Br^2) \quad r < r_c $$

between an atom and its corresponding tether site which will typically be a frozen atom in the simulation. $r_c$ is the cutoff.

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- A (energy units)
- B (1/distance^2 units)
- cutoff (distance units)
The last coefficient is optional. If not specified, the global cutoff is used.

Style gauss/cut computes a generalized Gaussian interaction potential between pairs of particles:

\[
E = \frac{H}{\sigma_h \sqrt{2\pi}} \exp \left[ -\frac{(r - r_{mh})^2}{2\sigma_h^2} \right]
\]

where H determines together with the standard deviation \(\sigma_h\) the peak height of the Gaussian function, and \(r_{mh}\) the peak position. Examples of the use of the Gaussian potentials include implicit solvent simulations of salt ions (Lenart) and of surfactants (Jusufi). In these instances the Gaussian potential mimics the hydration barrier between a pair of particles. The hydration barrier is located at \(r_{mh}\) and has a width of \(\sigma_h\). The prefactor determines the height of the potential barrier.

The following coefficients must be defined for each pair of atom types via the pair_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- H (energy * distance units)
- \(r_{mh}\) (distance units)
- \(\sigma_h\) (distance units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff is used.

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 19.111.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I \(!= J\), the A, B, H, \(\sigma_h\), \(r_{mh}\) parameters, and the cutoff distance for these pair styles can be mixed: A (energy units) \(\sqrt{1/B}\) (distance units, see below) H (energy units) \(\sigma_h\) (distance units) \(r_{mh}\) (distance units) cutoff (distance units):

The default mix value is geometric. Only \textit{arithmetic} and \textit{geometric} mix values are supported. See the “pair_modify” command for details.

The A and H parameters are mixed using the same rules normally used to mix the “epsilon” parameter in a Lennard Jones interaction. The \(\sigma_h\), \(r_{mh}\), and the cutoff distance are mixed using the same rules used to mix the “sigma” parameter in a Lennard Jones interaction. The B parameter is converted to a distance (sigma), before mixing (using \(B=\sigma_h^2\)), and converted back to a coefficient afterwards (using \(B=\sqrt{B}\)). Negative A values are converted to positive A values (using \(\text{abs}(A)\)) before mixing, and converted back after mixing (by multiplying by \(\text{min}(\text{sign}(A_i),\text{sign}(A_j))\)). This way, if either particle is repulsive (if \(A_i<0\) or \(A_j<0\)), then the default interaction between both particles will be repulsive.

The gauss style does not support the \textit{pair_modify} shift option. There is no effect due to the Gaussian well beyond the cutoff; hence reasonable cutoffs need to be specified.
The \textit{gauss/cut} style supports the \textit{pair_modify} shift option for the energy of the Gauss-potential portion of the pair interaction.

The \textit{pair_modify} table and tail options are not relevant for these pair styles.

These pair styles write their information to \textit{binary restart files}, so \textit{pair_style} and \textit{pair_coeff} commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the \textit{pair} keyword of the \textit{run_style respa} command. They do not support the \textit{inner}, \textit{middle}, \textit{outer} keywords.

The \textit{gauss} pair style tallies an “occupancy” count of how many Gaussian-well sites have an atom within the distance at which the force is a maximum = $\sqrt{0.5/b}$. This quantity can be accessed via the \textit{compute pair} command as a vector of values of length 1.

To print this quantity to the log file (with a descriptive column heading) the following commands could be included in an input script:

\begin{verbatim}
compute gauss all pair gauss
variable occ equal c_gauss[1]
thermo_style custom step temp epair v_occ
\end{verbatim}

\subsection{19.1.11.5 Restrictions}

The \textit{gauss} and \textit{gauss/cut} styles are part of the EXTRA-PAIR package. They are only enabled if LAMMPS is build with that package. See the \textit{Build package} page for more info.

The \textit{gauss} style does not apply \textit{special_bonds} factors. When using this pair style on a system that has bonds, the \textit{special_bonds} factors, if using the default setting of 0.0, may need to be adjusted to some very small number (e.g. 1.0e-100), so that those special pairs are not completely excluded from the neighbor lists, but won’t contribute forces or energies from styles (e.g. when used in combination with a \textit{hybrid pair style}) that do apply those factors.

\subsection{19.1.11.6 Related commands}

\textit{pair_coeff}, \textit{pair_style coul/diel}

19.112 pair_style gayberne command

Accelerator Variants: gayberne/gpu, gayberne/intel, gayberne/omp

19.112.1 Syntax

```
pair_style gayberne gamma upsilon mu cutoff
```

- `gamma` = shift for potential minimum (typically 1)
- `upsilon` = exponent for eta orientation-dependent energy function
- `mu` = exponent for chi orientation-dependent energy function
- `cutoff` = global cutoff for interactions (distance units)

19.112.2 Examples

```
pair_style gayberne 1.0 1.0 1.0 10.0
pair_coeff * * 1.0 1.7 1.7 3.4 3.4 1.0 1.0 1.0
```

19.112.3 Description

The `gayberne` styles compute a Gay-Berne anisotropic LJ interaction (Berardi) between pairs of ellipsoidal particles or an ellipsoidal and spherical particle via the formulas

\[
U(A_1, A_2) = U_r(A_1, A_2, r_{12}, \gamma) \cdot \eta_{12}(A_1, A_2, \upsilon) \cdot \chi_{12}(A_1, A_2, r_{12}, \mu)
\]

\[
U_r = 4\epsilon \frac{(\rho_{12}^2 - \rho_0^2)}{\sigma} = \frac{h_{12}}{h_{12} + \gamma \sigma}
\]

where \(A_1\) and \(A_2\) are the transformation matrices from the simulation box frame to the body frame and \(r_{12}\) is the center to center vector between the particles. \(U_r\) controls the shifted distance dependent interaction based on the distance of closest approach of the two particles \(h_{12}\) and the user-specified shift parameter gamma. When both particles are spherical, the formula reduces to the usual Lennard-Jones interaction (see details below for when Gay-Berne treats a particle as “spherical”).

For large uniform molecules it has been shown that the energy parameters are approximately representable in terms of local contact curvatures (Everaers):

\[
\epsilon_a = \sigma \cdot \frac{a}{b \cdot c}; \epsilon_b = \sigma \cdot \frac{b}{a \cdot c}; \epsilon_c = \sigma \cdot \frac{c}{a \cdot b}
\]

The variable names utilized as potential parameters are for the most part taken from (Everaers) in order to be consistent with the RE-squared pair potential. Details on the upsilon and mu parameters are given here.

More details of the Gay-Berne formulation are given in the references listed below and in this supplementary document.

Use of this pair style requires the NVE, NVT, or NPT fixes with the asphere extension (e.g. `fix nve/asphere`) in order to integrate particle rotation. Additionally, `atom_style ellipsoid` should be used since it defines the rotational state and the size and shape of each ellipsoidal particle.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:
• \(\epsilon\) = well depth (energy units)
• \(\sigma\) = minimum effective particle radii (distance units)
• \(\epsilon_{i,a}\) = relative well depth of type I for side-to-side interactions
• \(\epsilon_{i,b}\) = relative well depth of type I for face-to-face interactions
• \(\epsilon_{i,c}\) = relative well depth of type I for end-to-end interactions
• \(\epsilon_{j,a}\) = relative well depth of type J for side-to-side interactions
• \(\epsilon_{j,b}\) = relative well depth of type J for face-to-face interactions
• \(\epsilon_{j,c}\) = relative well depth of type J for end-to-end interactions
• cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff specified in the pair_style command is used.

It is typical with the Gay-Berne potential to define \(\sigma\) as the minimum of the 3 shape diameters of the particles involved in an I,I interaction, though this is not required. Note that this is a different meaning for \(\sigma\) than the pair_style resquared potential uses.

The \(\epsilon_i\) and \(\epsilon_j\) coefficients are actually defined for atom types, not for pairs of atom types. Thus, in a series of pair_coeff commands, they only need to be specified once for each atom type.

Specifically, if any of \(\epsilon_{i,a}\), \(\epsilon_{i,b}\), \(\epsilon_{i,c}\) are non-zero, the three values are assigned to atom type I. If all the \(\epsilon_i\) values are zero, they are ignored. If any of \(\epsilon_{j,a}\), \(\epsilon_{j,b}\), \(\epsilon_{j,c}\) are non-zero, the three values are assigned to atom type J. If all three \(\epsilon_j\) values are zero, they are ignored. Thus the typical way to define the \(\epsilon_i\) and \(\epsilon_j\) coefficients is to list their values in “pair_coeff I J” commands when I = J, but set them to 0.0 when I \neq J. If you do list them when I \neq J, you should insure they are consistent with their values in other pair_coeff commands, since only the last setting will be in effect.

Note: If the \(\epsilon_{a,b,c}\) for an atom type, and if the shape of the particle itself is spherical, meaning its 3 shape parameters are all the same, then the particle is treated as an LJ sphere by the Gay-Berne potential. This is significant because if two LJ spheres interact, then the simple Lennard-Jones formula is used to compute their interaction energy/force using the specified epsilon and sigma as the standard LJ parameters. This is much cheaper to compute than the full Gay-Berne formula. To treat the particle as a LJ sphere with sigma = D, you should normally set \(\epsilon_{a,b,c} = 1.0\), set the pair_coeff \(\sigma = D\), and also set the 3 shape parameters for the particle to D. The one exception is that if the 3 shape parameters are set to 0.0, which is a valid way in LAMMPS to specify a point particle, then the Gay-Berne potential will treat that as shape parameters of 1.0 (i.e. a LJ particle with \(\sigma = 1\)), since it requires finite-size particles. In this case you should still set the pair_coeff \(\sigma\) to 1.0 as well.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
19.112.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distance for this pair style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style supports the pair_modify shift option for the energy of the Lennard-Jones portion of the pair interaction, but only for sphere-sphere interactions. There is no shifting performed for ellipsoidal interactions due to the anisotropic dependence of the interaction.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

19.112.5 Restrictions

The gayberne style is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

These pair styles require that atoms store torque and a quaternion to represent their orientation, as defined by the atom_style. It also require they store a per-type shape. The particles cannot store a per-particle diameter.

This pair style requires that atoms be ellipsoids as defined by the atom_style ellipsoid command.

Particles acted on by the potential can be finite-size aspherical or spherical particles, or point particles. Spherical particles have all 3 of their shape parameters equal to each other. Point particles have all 3 of their shape parameters equal to 0.0.

The Gay-Berne potential does not become isotropic as r increases (Everaers). The distance-of-closest-approach approximation used by LAMMPS becomes less accurate when high-aspect ratio ellipsoids are used.

Accelerator Variants: gran/hooke/history/omp, gran/hooke/history/kk

19.115 pair_style gran/hertz/history command

Accelerator Variants: gran/hertz/history/omp

19.115.1 Syntax

```
pair_style style Kn Kt gamma_n gamma_t xmu dampflag keyword
```

- **style** = `gran/hooke` or `gran/hooke/history` or `gran/hertz/history`
- **Kn** = elastic constant for normal particle repulsion (force/distance units or pressure units - see discussion below)
- **Kt** = elastic constant for tangential contact (force/distance units or pressure units - see discussion below)
- **gamma_n** = damping coefficient for collisions in normal direction (1/time units or 1/time-distance units - see discussion below)
- **gamma_t** = damping coefficient for collisions in tangential direction (1/time units or 1/time-distance units - see discussion below)
- **xmu** = static yield criterion (unitless value between 0.0 and 1.0e4)
- **dampflag** = 0 or 1 if tangential damping force is excluded or included
- **keyword** = `limit_damping`
  ```
  limit_damping value = none
  limit damping to prevent attractive interaction
  ```

**Note:** Versions of LAMMPS before 9Jan09 had different style names for granular force fields. This is to emphasize the fact that the Hertzian equation has changed to model polydispersity more accurately. A side effect of the change is that the Kn, Kt, gamma_n, and gamma_t coefficients in the pair_style command must be specified with different values in order to reproduce calculations made with earlier versions of LAMMPS, even for monodisperse systems. See the NOTE below for details.
19.115.2 Examples

<table>
<thead>
<tr>
<th>pair_style</th>

</tr>
</tbody>
</table>

19.115.3 Description

The \textit{gran} styles use the following formulas for the frictional force between two granular particles, as described in (Brilliantov), (Silbert), and (Zhang), when the distance \(r\) between two particles of radii \(R_i\) and \(R_j\) is less than their contact distance \(d = R_i + R_j\). There is no force between the particles when \(r > d\).

The two Hookean styles use this formula:

\[
F_{hk} = (k_n \delta n_{ij} - m_{eff} \gamma_n v_n) - (k_t \Delta s_t + m_{eff} \gamma_t v_t)
\]

The Hertzian style uses this formula:

\[
F_{hz} = \sqrt{\delta} \left( \frac{R_i R_j}{R_i + R_j} \right) F_{hk} = \sqrt{\delta} \left( \frac{R_i R_j}{R_i + R_j} \left[ (k_n \delta n_{ij} - m_{eff} \gamma_n v_n) - (k_t \Delta s_t + m_{eff} \gamma_t v_t) \right] \right)
\]

In both equations the first parenthesized term is the normal force between the two particles and the second parenthesized term is the tangential force. The normal force has 2 terms, a contact force and a damping force. The tangential force also has 2 terms: a shear force and a damping force. The shear force is a “history” effect that accounts for the tangential displacement between the particles for the duration of the time they are in contact. This term is included in pair styles \textit{hooke/history} and \textit{hertz/history}, but is not included in pair style \textit{hooke}. The tangential damping force term is included in all three pair styles if \textit{dampflag} is set to 1; it is not included if \textit{dampflag} is set to 0.

The other quantities in the equations are as follows:

- \(\delta = d - r\) = overlap distance of 2 particles
- \(K_n\) = elastic constant for normal contact
- \(K_t\) = elastic constant for tangential contact
- \(\gamma_n\) = viscoelastic damping constant for normal contact
- \(\gamma_t\) = viscoelastic damping constant for tangential contact
- \(m_{eff} = M_i M_j / (M_i + M_j)\) = effective mass of 2 particles of mass \(M_i\) and \(M_j\)
- \(\Delta s_t\) = tangential displacement vector between 2 particles which is truncated to satisfy a frictional yield criterion
- \(n_{ij}\) = unit vector along the line connecting the centers of the 2 particles
- \(V_n\) = normal component of the relative velocity of the 2 particles
- \(V_t\) = tangential component of the relative velocity of the 2 particles

The \(K_n\), \(K_t\), \(\gamma_n\), and \(\gamma_t\) coefficients are specified as parameters to the pair\_style command. If a NULL is used for \(K_t\), then a default value is used where \(K_t = 2/7 K_n\). If a NULL is used for \(\gamma_t\), then a default value is used where \(\gamma_t = 1/2 \gamma_n\).

The interpretation and units for these 4 coefficients are different in the Hookean versus Hertzian equations.

The Hookean model is one where the normal push-back force for two overlapping particles is a linear function of the overlap distance. Thus the specified \(K_n\) is in units of (force/distance). Note that this push-back force is independent of absolute particle size (in the monodisperse case) and of the relative sizes of the two particles (in the polydisperse case).
case). This model also applies to the other terms in the force equation so that the specified $\gamma_n$ is in units of (1/time), $K_t$ is in units of (force/distance), and $\gamma_t$ is in units of (1/time).

The Hertzian model is one where the normal push-back force for two overlapping particles is proportional to the area of overlap of the two particles, and is thus a non-linear function of overlap distance. Thus $K_n$ has units of force per area and is thus specified in units of (pressure). The effects of absolute particle size (monodispersity) and relative size (polydispersity) are captured in the radii-dependent prefactors. When these prefactors are carried through to the other terms in the force equation it means that the specified $\gamma_n$ is in units of (1/(time*distance)), $K_t$ is in units of (pressure), and $\gamma_t$ is in units of (1/(time*distance)).

Note that in the Hookean case, $K_n$ can be thought of as a linear spring constant with units of force/distance. In the Hertzian case, $K_n$ is like a non-linear spring constant with units of force/area or pressure, and as shown in the (Zhang) paper, $K_n = 4G/(3(1-\nu))$ where $\nu$ = the Poisson ratio, $G$ = shear modulus = $E/(2(1+\nu))$, and $E$ = Young’s modulus. Similarly, $K_t = 4G/(2-\nu)$. (NOTE: in an earlier version of the manual, we incorrectly stated that $K_t = 8G/(2-\nu)$.)

Thus in the Hertzian case $K_n$ and $K_t$ can be set to values that corresponds to properties of the material being modeled. This is also true in the Hookean case, except that a spring constant must be chosen that is appropriate for the absolute size of particles in the model. Since relative particle sizes are not accounted for, the Hookean styles may not be a suitable model for polydisperse systems.

Note: In versions of LAMMPS before 9Jan09, the equation for Hertzian interactions did not include the $\sqrt{r_ir_j/(r_i+r_j)}$ term and thus was not as accurate for polydisperse systems. For monodisperse systems, $\sqrt{r_ir_j/(r_i+r_j)}$ is a constant factor that effectively scales all 4 coefficients: $K_n, K_t, \gamma_n, \gamma_t$. Thus you can set the values of these 4 coefficients appropriately in the current code to reproduce the results of a previous Hertzian monodisperse calculation. For example, for the common case of a monodisperse system with particles of diameter 1, all 4 of these coefficients should now be set 2x larger than they were previously.

Xmu is also specified in the pair_style command and is the upper limit of the tangential force through the Coulomb criterion $F_t = xmu*F_n$, where $F_t$ and $F_n$ are the total tangential and normal force components in the formulas above. Thus in the Hookean case, the tangential force between 2 particles grows according to a tangential spring and dash-pot model until $F_t/F_n = xmu$ and is then held at $F_t = F_n*xmu$ until the particles lose contact. In the Hertzian case, a similar analogy holds, though the spring is no longer linear.

Note: Normally, xmu should be specified as a fractional value between 0.0 and 1.0, however LAMMPS allows large values (up to 1.0e4) to allow for modeling of systems which can sustain very large tangential forces.

The effective mass $m_{eff}$ is given by the formula above for two isolated particles. If either particle is part of a rigid body, its mass is replaced by the mass of the rigid body in the formula above. This is determined by searching for a fix rigid command (or its variants).

For granular styles there are no additional coefficients to set for each pair of atom types via the pair_coeff command. All settings are global and are made via the pair_style command. However you must still use the pair_coeff for all pairs of granular atom types. For example the command

```plaintext
pair_coeff * *
```

should be used if all atoms in the simulation interact via a granular potential (i.e. one of the pair styles above is used). If a granular potential is used as a sub-style of pair_style hybrid, then specific atom types can be used in the pair_coeff command to determine which atoms interact via a granular potential.

If two particles are moving away from each other while in contact, there is a possibility that the particles could experience an effective attractive force due to damping. If the limit_damping keyword is used, this option will zero out the normal component of the force if there is an effective attractive force.
Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

---

### 19.115.4 Mixing, shift, table, tail correction, restart, rRESPA info

The `pair_modify` mix, shift, table, and tail options are not relevant for granular pair styles.

These pair styles write their information to binary restart files, so a pair_style command does not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the `pair` keyword of the `run_style respa` command. They do not support the `inner`, `middle`, `outer` keywords.

The single() function of these pair styles returns 0.0 for the energy of a pairwise interaction, since energy is not conserved in these dissipative potentials. It also returns only the normal component of the pairwise interaction force. However, the single() function also calculates 10 extra pairwise quantities. The first 3 are the components of the tangential force between particles I and J, acting on particle I. The fourth is the magnitude of this tangential force. The next 3 (5-7) are the components of the relative velocity in the normal direction (along the line joining the 2 sphere centers). The last 3 (8-10) the components of the relative velocity in the tangential direction.

These extra quantities can be accessed by the `compute pair/local` command, as `p1`, `p2`, ..., `p10`.

---

### 19.115.5 Restrictions

All the granular pair styles are part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

These pair styles require that atoms store torque and angular velocity (omega) as defined by the `atom_style`. They also require a per-particle radius is stored. The `sphere` atom style does all of this.

This pair style requires you to use the `comm_modify vel yes` command so that velocities are stored by ghost atoms.

These pair styles will not restart exactly when using the `read_restart` command, though they should provide statistically similar results. This is because the forces they compute depend on atom velocities. See the `read_restart` command for more details.

19.116.3 Description

The granular styles support a variety of options for the normal, tangential, rolling and twisting forces resulting from contact between two granular particles. This expands on the options offered by the pair gran/* pair styles. The total computed forces and torques are the sum of various models selected for the normal, tangential, rolling and twisting modes of motion.

All model choices and parameters are entered in the pair_coeff command, as described below. Unlike e.g. pair gran/hooke, coefficient values are not global, but can be set to different values for different combinations of particle types, as determined by the pair_coeff command. If the contact model choice is the same for two particle types, the mixing for the cross-coefficients can be carried out automatically. This is shown in the last example, where model choices are the same for type 1 - type 1 as for type 2 - type 2 interactions, but coefficients are different. In this case, the mixed coefficients for type 1 - type 2 interactions can be determined from mixing rules discussed below. For additional flexibility, coefficients as well as model forms can vary between particle types, as shown in the fourth example: type 1 interactions are based on a Johnson-Kendall-Roberts normal contact model and 2-2 interactions are based on a DMT cohesive model (see below). In that example, 1-1 and 2-2 interactions have different model forms, in which case mixing of coefficients cannot be determined, so 1-2 interactions must be explicitly defined via the pair_coeff 1 * command, otherwise an error would result.

The first required keyword for the pair_coeff command is the normal contact model. Currently supported options for normal contact models and their required arguments are:

1. hooke : $k_n$, $\eta_{n0}$ (or $e$)
2. hertz : $k_n$, $\eta_{n0}$ (or $e$)
3. hertz/material : $E$, $\eta_{n0}$ (or $e$), $\nu$
4. dmt : $E$, $\eta_{n0}$ (or $e$), $\nu$, $\gamma$
5. jkr : $E$, $\eta_{n0}$ (or $e$), $\nu$, $\gamma$

Here, $k_n$ is spring stiffness (with units that depend on model choice, see below); $\eta_{n0}$ is a damping prefactor (or, in its place a coefficient of restitution $e$, depending on the choice of damping mode, see below); $E$ is Young’s modulus in units of force/length^2, i.e. pressure; $\nu$ is Poisson’s ratio and $\gamma$ is a surface energy density, in units of energy/length^2.

For the hooke model, the normal, elastic component of force acting on particle $i$ due to contact with particle $j$ is given by:

$$F_{ne,Hooke} = k_n \delta_{ij} \mathbf{n}$$

Where $\delta_{ij} = R_i + R_j - \|\mathbf{r}_{ij}\|$ is the particle overlap, $R_i, R_j$ are the particle radii, $\mathbf{r}_{ij} = \mathbf{r}_i - \mathbf{r}_j$ is the vector separating the two particle centers (note the i-j ordering so that $F_{ne}$ is positive for repulsion), and $\mathbf{n} = \frac{\mathbf{r}_{ij}}{\|\mathbf{r}_{ij}\|}$. Therefore, for hooke, the units of the spring constant $k_n$ are force/distance, or equivalently mass/time^2.

For the hertz model, the normal component of force is given by:

$$F_{ne,Hertz} = k_n R_{eff}^{1/2} \delta_{ij}^{3/2} \mathbf{n}$$

Here, $R_{eff} = \frac{R_i R_j}{R_i + R_j}$ is the effective radius, denoted for simplicity as $R$ from here on. For hertz, the units of the spring constant $k_n$ are force/length^2, or equivalently pressure.

For the hertz/material model, the force is given by:

$$F_{ne,Hertz/material} = \frac{4}{3} E_{eff} R_{eff}^{1/2} \delta_{ij}^{3/2} \mathbf{n}$$

Here, $E_{eff} = E = \left( \frac{1-\nu_i^2}{E_i} + \frac{1-\nu_j^2}{E_j} \right)^{-1}$ is the effective Young’s modulus, with $\nu_i, \nu_j$ the Poisson ratios of the particles of types $i$ and $j$. Note that if the elastic modulus and the shear modulus of the two particles are the same, the hertz/material model is equivalent to the hertz model with $k_n = 4/3 E_{eff}$.
The *dmt* model corresponds to the *(Derjaguin-Muller-Toporov)* cohesive model, where the force is simply Hertz with an additional attractive cohesion term:

\[ F_{ne,dmt} = \left( \frac{4}{3} E R^{1/2} \delta^{3/2} - 4\pi R \right) n \]

The *jkr* model is the *(Johnson-Kendall-Roberts)* model, where the force is computed as:

\[ F_{ne,jkr} = \left( \frac{4Ea^3}{3R} - 2\pi a^2 \sqrt{\frac{4\gamma E}{\pi a}} \right) n \]

Here, \( a \) is the radius of the contact zone, related to the overlap \( \delta \) according to:

\[ \delta = a^2 / R - 2\sqrt{\pi \gamma a / E} \]

LAMMPS internally inverts the equation above to solve for \( a \) in terms of \( \delta \), then solves for the force in the previous equation. Additionally, note that the JKR model allows for a tensile force beyond contact (i.e. for \( \delta < 0 \)), up to a maximum of \( 3\pi \gamma R \) (also known as the 'pull-off' force). Note that this is a hysteretic effect, where particles that are not contacting initially will not experience force until they come into contact \( \delta \geq 0 \); as they move apart and \( \delta < 0 \), they experience a tensile force up to \( 3\pi \gamma R \), at which point they lose contact.

In addition, the normal force is augmented by a damping term of the following general form:

\[ F_{n,damp} = -\eta_n v_{n,rel} \]

Here, \( v_{n,rel} = (v_j - v_i) \cdot n \) is the component of relative velocity along \( n \).

The optional *damping* keyword to the *pair_coeff* command followed by a keyword determines the model form of the damping factor \( \eta_n \), and the interpretation of the \( \eta_{n0} \) or \( e \) coefficients specified as part of the normal contact model settings. The *damping* keyword and corresponding model form selection may be appended anywhere in the *pair coeff* command. Note that the choice of damping model affects both the normal and tangential damping (and depending on other settings, potentially also the twisting damping). The options for the damping model currently supported are:

1. *velocity*
2. *mass_velocity*
3. *viscoelastic*
4. *tsui*

If the *damping* keyword is not specified, the *viscoelastic* model is used by default.

For *damping velocity*, the normal damping is simply equal to the user-specified damping coefficient in the *normal* model:

\[ \eta_n = \eta_{n0} \]

Here, \( \eta_{n0} \) is the damping coefficient specified for the normal contact model, in units of mass/time.

For *damping mass_velocity*, the normal damping is given by:

\[ \eta_n = \eta_{n0} m_{eff} \]

Here, \( \eta_{n0} \) is the damping coefficient specified for the normal contact model, in units of 1/time and \( m_{eff} = m_i m_j / (m_i + m_j) \) is the effective mass. Use *damping mass_velocity* to reproduce the damping behavior of *pair granular/hooke*.

The *damping viscoelastic* model is based on the viscoelastic treatment of *(Brilliantov et al)*, where the normal damping is given by:

\[ \eta_n = \eta_{n0} a m_{eff} \]
Here, $a$ is the contact radius, given by $a = \sqrt{R \delta}$ for all models except $jkr$, for which it is given implicitly according to
$$\delta = a^2/R - 2\sqrt{\pi \gamma a/E}.$$ For damping viscoelastic, $\eta_{n0}$ is in units of \textit{1/(time*distance)}.

The \textit{tsuji} model is based on the work of \textit{(Tsuji et al)}. Here, the damping coefficient specified as part of the normal model is interpreted as a restitution coefficient $e$. The damping constant $\eta_n$ is given by:

$$\eta_n = \alpha (m_{ef} k_n)^{1/2}$$

For normal contact models based on material parameters, $k_n = 4/3Ea$. The parameter $\alpha$ is related to the restitution coefficient $e$ according to:

$$\alpha = 1.2728 - 4.2783e + 11.087e^2 - 22.348e^3 + 27.467e^4 - 18.022e^5 + 4.8218e^6$$

The dimensionless coefficient of restitution $e$ specified as part of the normal contact model parameters should be between 0 and 1, but no error check is performed on this.

The total normal force is computed as the sum of the elastic and damping components:

$$F_n = F_{ne} + F_{n,damp}$$

The \textit{pair_coeff} command also requires specification of the tangential contact model. The required keyword \textit{tangential} is expected, followed by the model choice and associated parameters. Currently supported tangential model choices and their expected parameters are as follows:

1. \textit{linear_nohistory} : $x_{\gamma,t}, \mu_s$
2. \textit{linear_history} : $k_t, x_{\gamma,t}, \mu_s$
3. \textit{mindlin} : $k_t$ or \textit{NULL}, $x_{\gamma,t}, \mu_s$
4. \textit{mindlin/force} : $k_t$ or \textit{NULL}, $x_{\gamma,t}, \mu_s$
5. \textit{mindlin_rescale} : $k_t$ or \textit{NULL}, $x_{\gamma,t}, \mu_s$
6. \textit{mindlin_rescale/force} : $k_t$ or \textit{NULL}, $x_{\gamma,t}, \mu_s$

Here, $x_{\gamma,t}$ is a dimensionless multiplier for the normal damping $\eta_n$ that determines the magnitude of the tangential damping, $\mu_s$ is the tangential (or sliding) friction coefficient, and $k_t$ is the tangential stiffness coefficient.

For tangential \textit{linear_nohistory}, a simple velocity-dependent Coulomb friction criterion is used, which mimics the behavior of the \textit{pair gran/hooke} style. The tangential force $F_t$ is given by:

$$F_t = -\min(\mu_t F_{n0}, \|F_{t,damp}\|) t$$

The tangential damping force $F_{t,damp}$ is given by:

$$F_{t,damp} = -\eta_t v_{t,rel}$$

The tangential damping prefactor $\eta_t$ is calculated by scaling the normal damping $\eta_n$ (see above):

$$\eta_t = -x_{\gamma,t} \eta_n$$

The normal damping prefactor $\eta_n$ is determined by the choice of the \textit{damping} keyword, as discussed above. Thus, the \textit{damping} keyword also affects the tangential damping. The parameter $x_{\gamma,t}$ is a scaling coefficient. Several works in the literature use $x_{\gamma,t} = 1$ \textit{(Marshall, Tsuji et al, Silbert et al)}. The relative tangential velocity at the point of contact is given by $v_{t,rel} = v_i - (R_i \Omega_i + R_j \Omega_j) \times n$, where $v_i = v_r - v_r \cdot n n, v_r = v_j - v_i$. The direction of the applied force is $t = v_{t,rel}/\|v_{t,rel}\|$.
The normal force value $F_{n0}$ used to compute the critical force depends on the form of the contact model. For non-cohesive models (hertz, hertz/material, hooke), it is given by the magnitude of the normal force:

$$F_{n0} = \|F_n\|$$

For cohesive models such as jkr and dmt, the critical force is adjusted so that the critical tangential force approaches $\mu F_{pulloff}$, see Marshall, equation 43, and Thornton. For both models, $F_{n0}$ takes the form:

$$F_{n0} = \|F_{ne} + 2F_{pulloff}\|$$

Where $F_{pulloff} = 3\pi\gamma R$ for jkr, and $F_{pulloff} = 4\pi\gamma R$ for dmt.

The remaining tangential options all use accumulated tangential displacement (i.e. contact history), except for the options mindlin/force and mindlin_rescale/force, that use accumulated tangential force instead, and are discussed further below. The accumulated tangential displacement is discussed in details below in the context of the linear_history option. The same treatment of the accumulated displacement applies to the other options as well.

For tangential linear_history, the tangential force is given by:

$$F_t = -\min(\mu_t F_{n0}, \| -k_t \xi + F_{t,damp}\|)t$$

Here, $\xi$ is the tangential displacement accumulated during the entire duration of the contact:

$$\xi = \int_{t_0}^{t} v_{t,rel}(\tau)d\tau$$

This accumulated tangential displacement must be adjusted to account for changes in the frame of reference of the contacting pair of particles during contact. This occurs due to the overall motion of the contacting particles in a rigid-body-like fashion during the duration of the contact. There are two modes of motion that are relevant: the ‘tumbling’ rotation of the contacting pair, which changes the orientation of the plane in which tangential displacement occurs; and ‘spinning’ rotation of the contacting pair about the vector connecting their centers of mass ($n$). Corrections due to the former mode of motion are made by rotating the accumulated displacement into the plane that is tangential to the contact vector at each step, or equivalently removing any component of the tangential displacement that lies along $n$, and rescaling to preserve the magnitude. This follows the discussion in Luding, see equation 17 and relevant discussion in that work:

$$\xi = (\xi' - (n \cdot \xi')n) \frac{\|\xi'\|}{\|\xi' - (n \cdot \xi')n\|}$$

Here, $\xi'$ is the accumulated displacement prior to the current time step and $\xi$ is the corrected displacement. Corrections to the displacement due to the second mode of motion described above (rotations about $n$) are not currently implemented, but are expected to be minor for most simulations.

Furthermore, when the tangential force exceeds the critical force, the tangential displacement is re-scaled to match the value for the critical force (see Luding, equation 20 and related discussion):

$$\xi = -\frac{1}{k_t} (\mu_t F_{n0}t - F_{t,damp})$$

The tangential force is added to the total normal force (elastic plus damping) to produce the total force on the particle. The tangential force also acts at the contact point (defined as the center of the overlap region) to induce a torque on each particle according to:

$$\tau_i = -(R_i - 0.5\delta)n \times F_t$$

$$\tau_j = -(R_j - 0.5\delta)n \times F_t$$

For tangential mindlin, the Mindlin no-slip solution is used which differs from the linear_history option by an additional factor of $a$, the radius of the contact region. The tangential force is given by:

$$F_t = -\min(\mu_t F_{n0}, \| -k_t a\xi + F_{t,damp}\|)t$$
Here, $a$ is the radius of the contact region, given by $a = \sqrt{R\delta}$ for all normal contact models, except for jkr, where it is given implicitly by $\delta = a^2/R - 2\sqrt{\pi\gamma a/E}$, see discussion above. To match the Mindlin solution, one should set $k_t = 8G_{eff}$, where $G_{eff}$ is the effective shear modulus given by:

$$G_{eff} = \left(\frac{2 - \nu_i}{G_i} + \frac{2 - \nu_j}{G_j}\right)^{-1}$$

where $G$ is the shear modulus, related to Young’s modulus $E$ and Poisson’s ratio $\nu$ by $G = E/(2(1 + \nu))$. This can also be achieved by specifying NULL for $k_t$, in which case a normal contact model that specifies material parameters $E$ and $\nu$ is required (e.g. hertz/material, dmt or jkr). In this case, mixing of the shear modulus for different particle types $i$ and $j$ is done according to the formula above.

**Note:** The radius of the contact region $a$ depends on the normal overlap. As a result, the tangential force for mindlin can change due to a variation in normal overlap, even with no change in tangential displacement.

For *tangential mindlin/force*, the accumulated elastic tangential force characterizes the contact history, instead of the accumulated tangential displacement. This prevents the dependence of the tangential force on the normal overlap as noted above. The tangential force is given by:

$$F_t = -\min(\mu_t F_{n0}, \|F_{te} + F_{t,damp}\|)t$$

The increment of the elastic component of the tangential force $F_{te}$ is given by:

$$dF_{te} = -k_t a v_{t,rel} d\tau$$

The changes in frame of reference of the contacting pair of particles during contact are accounted for by the same formula as above, replacing the accumulated tangential displacement $\xi$, by the accumulated tangential elastic force $F_{te}$. When the tangential force exceeds the critical force, the tangential force is directly re-scaled to match the value for the critical force:

$$F_{te} = -\mu_t F_{n0}t + F_{t,damp}$$

The same rules as those described for mindlin apply regarding the tangential stiffness and mixing of the shear modulus for different particle types.

The *mindlin_rescale* option uses the same form as mindlin, but the magnitude of the tangential displacement is re-scaled as the contact unloads, i.e. if $a < a_{t_n-1}$:

$$\xi = \xi_{t_n-1} \frac{a}{a_{t_n-1}}$$

Here, $t_n-1$ indicates the value at the previous time step. This rescaling accounts for the fact that a decrease in the contact area upon unloading leads to the contact being unable to support the previous tangential loading, and spurious energy is created without the rescaling above (Walton).

**Note:** For mindlin, a decrease in the tangential force already occurs as the contact unloads, due to the dependence of the tangential force on the normal force described above. By re-scaling $\xi$, *mindlin_rescale* effectively re-scales the tangential force twice, i.e., proportionally to $a^2$. This peculiar behavior results from use of the accumulated tangential displacement to characterize the contact history. Although *mindlin_rescale* remains available for historic reasons and backward compatibility purposes, it should be avoided in favor of *mindlin_rescale/force*.

The *mindlin_rescale/force* option uses the same form as mindlin/force, but the magnitude of the tangential elastic force is re-scaled as the contact unloads, i.e. if $a < a_{t_n-1}$:

$$F_{te} = F_{te,t_n-1} \frac{a}{a_{t_n-1}}$$
This approach provides a better approximation of the Mindlin-Deresiewicz laws and is more consistent than mindlin_rescale. See discussions in Thornton et al, 2013, particularly equation 18(b) of that work and associated discussion, and Agnin and Roux, 2007, particularly Appendix A.

The optional rolling keyword enables rolling friction, which resists pure rolling motion of particles. The options currently supported are:

1. none
2. sds : \( k_{\text{roll}}, \gamma_{\text{roll}}, \mu_{\text{roll}} \)

If the rolling keyword is not specified, the model defaults to none.

For rolling sds, rolling friction is computed via a spring-dashpot-slider, using a ‘pseudo-force’ formulation, as detailed by Luding. Unlike the formulation in Marshall, this allows for the required adjustment of rolling displacement due to changes in the frame of reference of the contacting pair. The rolling pseudo-force is computed analogously to the tangential force:

\[
F_{\text{roll},0} = k_{\text{roll}} \xi_{\text{roll}} - \gamma_{\text{roll}} v_{\text{roll}}
\]

Here, \( v_{\text{roll}} = - R(\Omega_i - \Omega_j) \times n \) is the relative rolling velocity, as given in Wang et al and Luding. This differs from the expressions given by Kuhn and Bagi and used in Marshall; see Wang et al for details. The rolling displacement is given by:

\[
\xi_{\text{roll}} = \int_{t_0}^t v_{\text{roll}}(\tau) d\tau
\]

A Coulomb friction criterion truncates the rolling pseudo-force if it exceeds a critical value:

\[
F_{\text{roll}} = \min(\mu_{\text{roll}} F_{n,0}, \| F_{\text{roll},0} \|) k
\]

Here, \( k = v_{\text{roll}} / \| v_{\text{roll}} \| \) is the direction of the pseudo-force. As with tangential displacement, the rolling displacement is rescaled when the critical force is exceeded, so that the spring length corresponds the critical force. Additionally, the displacement is adjusted to account for rotations of the frame of reference of the two contacting particles in a manner analogous to the tangential displacement.

The rolling pseudo-force does not contribute to the total force on either particle (hence ‘pseudo’), but acts only to induce an equal and opposite torque on each particle, according to:

\[
\tau_{\text{roll},i} = R_{\text{eff}} n \times F_{\text{roll}}
\]

\[
\tau_{\text{roll},j} = -\tau_{\text{roll},i}
\]

The optional twisting keyword enables twisting friction, which resists rotation of two contacting particles about the vector \( n \) that connects their centers. The options currently supported are:

1. none
2. sds : \( k_{\text{twist}}, \gamma_{\text{twist}}, \mu_{\text{twist}} \)
3. marshall

If the twisting keyword is not specified, the model defaults to none.

For both twisting sds and twisting marshall, a history-dependent spring-dashpot-slider is used to compute the twisting torque. Because twisting displacement is a scalar, there is no need to adjust for changes in the frame of reference due to rotations of the particle pair. The formulation in Marshall therefore provides the most straightforward treatment:

\[
\tau_{\text{twist},0} = -k_{\text{twist}} \xi_{\text{twist}} - \gamma_{\text{twist}} \Omega_{\text{twist}}
\]
Here $\xi_{\text{twist}} = \int_{t_0}^{t} \Omega_{\text{twist}}(\tau) d\tau$ is the twisting angular displacement, and $\Omega_{\text{twist}} = (\Omega_i - \Omega_j) \cdot n$ is the relative twisting angular velocity. The torque is then truncated according to:

$$\tau_{\text{twist}} = \min(\mu_{\text{twist}} F_{n,0}, \tau_{\text{twist},0})$$

Similar to the sliding and rolling displacement, the angular displacement is rescaled so that it corresponds to the critical value if the twisting torque exceeds this critical value:

$$\xi_{\text{twist}} = \frac{1}{k_{\text{twist}}} (\mu_{\text{twist}} F_{n,0} \text{sgn}(\Omega_{\text{twist}}) - \gamma_{\text{twist}} \Omega_{\text{twist}})$$

For twisting sds, the coefficients $k_{\text{twist}}, \gamma_{\text{twist}}$ and $\mu_{\text{twist}}$ are simply the user input parameters that follow the twisting sds keywords in the pair_coeff command.

For twisting_marshall, the coefficients are expressed in terms of sliding friction coefficients, as discussed in Marshall (see equations 32 and 33 of that work):

$$k_{\text{twist}} = 0.5 k_a a^2$$
$$\eta_{\text{twist}} = 0.5 \eta a^2$$
$$\mu_{\text{twist}} = \frac{2}{3} a \mu_t$$

Finally, the twisting torque on each particle is given by:

$$\tau_{\text{twist},i} = \tau_{\text{twist}} n$$
$$\tau_{\text{twist},j} = -\tau_{\text{twist},i}$$

If two particles are moving away from each other while in contact, there is a possibility that the particles could experience an effective attractive force due to damping. If the optional limit_damping keyword is used, this option will zero out the normal component of the force if there is an effective attractive force. This keyword cannot be used with the JKR or DMT models.

The granular pair style can reproduce the behavior of the pair gran/* styles with the appropriate settings (some very minor differences can be expected due to corrections in displacement history frame-of-reference, and the application of the torque at the center of the contact rather than at each particle). The first example above is equivalent to pair gran/hooke 1000.0 NULL 50.0 50.0 0.4 1. The second example is equivalent to pair gran/hooke/history 1000.0 500.0 50.0 50.0 0.4 1. The third example is equivalent to pair gran/hertz/history 1000.0 500.0 50.0 50.0 0.4 1.

LAMMPS automatically sets pairwise cutoff values for pair_style granular based on particle radii (and in the case of jkr pull-off distances). In the vast majority of situations, this is adequate. However, a cutoff value can optionally be appended to the pair_style granular command to specify a global cutoff (i.e. a cutoff for all atom types). Additionally, the optional cutoff keyword can be passed to the pair_coeff command, followed by a cutoff value. This will set a pairwise cutoff for the atom types in the pair_coeff command. These options may be useful in some rare cases where the automatic cutoff determination is not sufficient, e.g. if particle diameters are being modified via the fix adapt command. In that case, the global cutoff specified as part of the pair_style granular command is applied to all atom types, unless it is overridden for a given atom type combination by the cutoff value specified in the pair_coeff command. If cutoff is only specified in the pair_coeff command and no global cutoff is appended to the pair_style granular command, then LAMMPS will use that cutoff for the specified atom type combination, and automatically set pairwise cutoffs for the remaining atom types.
Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 19.116.4 Mixing, shift, table, tail correction, restart, rRESPA info

The `pair_modify` mix, shift, table, and tail options are not relevant for granular pair styles.

Mixing of coefficients is carried out using geometric averaging for most quantities, e.g. if friction coefficient for type 1-type 1 interactions is set to $\mu_1$, and friction coefficient for type 2-type 2 interactions is set to $\mu_2$, the friction coefficient for type1-type2 interactions is computed as $\sqrt{\mu_1 \mu_2}$ (unless explicitly specified to a different value by a `pair_coeff 1 2 ...` command). The exception to this is elastic modulus, only applicable to hertz/material, dmt and jkr normal contact models. In that case, the effective elastic modulus is computed as:

$$E_{eff,ij} = \left( \frac{1 - \nu_i^2}{E_i} + \frac{1 - \nu_j^2}{E_j} \right)^{-1}$$

If the $i$-$j$ coefficients $E_{ij}$ and $\nu_{ij}$ are explicitly specified, the effective modulus is computed as:

$$E_{eff,ij} = \left( \frac{1 - \nu_{ij}^2}{E_{ij}} + \frac{1 - \nu_{ij}^2}{E_{ij}} \right)^{-1}$$

or

$$E_{eff,ij} = \frac{E_{ij}}{2(1 - \nu_{ij})}$$

These pair styles write their information to binary restart files, so a `pair_style` command does not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the `pair` keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

The single() function of these pair styles returns 0.0 for the energy of a pairwise interaction, since energy is not conserved in these dissipative potentials. It also returns only the normal component of the pairwise interaction force. However, the single() function also calculates 12 extra pairwise quantities. The first 3 are the components of the tangential force between particles I and J, acting on particle I. The fourth is the magnitude of this tangential force. The next 3 (5-7) are the components of the rolling torque acting on particle I. The next entry (8) is the magnitude of the rolling torque. The next entry (9) is the magnitude of the twisting torque acting about the vector connecting the two particle centers. The last 3 (10-12) are the components of the vector connecting the centers of the two particles ($x_I - x_J$).

These extra quantities can be accessed by the compute pair/local command, as $p1, p2, \ldots, p12$.
19.116.5 Restrictions

All the granular pair styles are part of the GRANULAR package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

These pair styles require that atoms store torque and angular velocity (omega) as defined by the atom_style. They also require a per-particle radius is stored. The sphere atom style does all of this.

This pair style requires you to use the comm_modify vel yes command so that velocities are stored by ghost atoms.

These pair styles will not restart exactly when using the read_restart command, though they should provide statistically similar results. This is because the forces they compute depend on atom velocities. See the read_restart command for more details.

pair_style lj/gromacs/coul/gromacs 8.0 10.0 7.0 9.0
pair_coeff * * 100.0 2.0
```
19.118.3 Description

The lj/gromacs styles compute shifted LJ and Coulombic interactions with an additional switching function $S(r)$ that ramps the energy and force smoothly to zero between an inner and outer cutoff. It is a commonly used potential in the GROMACS MD code and for the coarse-grained models of (Marrink).

$$E_{LJ} = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right] + S_{LJ}(r) \quad r < r_c$$

$$E_C = \frac{C_i q_i q_j}{\epsilon r} + S_C(r) \quad r < r_c$$

$$S(r) = C \quad r < r_1$$

$$S(r) = \frac{A}{3}(r-r_1)^3 + \frac{B}{4}(r-r_1)^4 + C \quad r_1 < r < r_c$$

$$A = -(3E'(r_c) + (r_c - r_1)E''(r_c))/(r_c - r_1)^2$$

$$B = (2E'(r_c) - (r_c - r_1)E''(r_c))/(r_c - r_1)^3$$

$$C = -E(r_c) + \frac{1}{2}(r_c - r_1)E'(r_c) - \frac{1}{12}(r_c - r_1)^2E''(r_c)$$

$r_1$ is the inner cutoff; $r_c$ is the outer cutoff. The coefficients $A$, $B$, and $C$ are computed by LAMMPS to perform the shifting and smoothing. The function $S(r)$ is actually applied once to each term of the LJ formula and once to the Coulombic formula, so there are 2 or 3 sets of $A$, $B$, $C$ coefficients depending on which pair_style is used. The boundary conditions applied to the smoothing function are as follows: $S'(r_1) = S''(r_1) = 0, S(r_c) = -E(r_c), S'(r_c) = -E'(r_c)$, and $S''(r_c) = -E''(r_c)$, where $E(r)$ is the corresponding term in the LJ or Coulombic potential energy function. Single and double primes denote first and second derivatives with respect to $r$, respectively.

The inner and outer cutoff for the LJ and Coulombic terms can be the same or different depending on whether 2 or 4 arguments are used in the pair_style command. The inner LJ cutoff must be $> 0$, but the inner Coulombic cutoff can be $>= 0$.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- $\epsilon$ (energy units)
- $\sigma$ (distance units)
- inner (distance units)
- outer (distance units)

Note that sigma is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum at $2^{1/6}\sigma$.

The last 2 coefficients are optional inner and outer cutoffs for style lj/gromacs. If not specified, the global inner and outer values are used.

The last 2 coefficients cannot be used with style lj/gromacs/coul/gromacs because this force field does not allow varying cutoffs for individual atom pairs; all pairs use the global cutoff(s) specified in the pair_style command.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.
You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script. See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 19.118.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I != J, the epsilon and sigma coefficients and cutoff distance for all of the lj/cut pair styles can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

None of the GROMACS pair styles support the `pair_modify` shift option, since the Lennard-Jones portion of the pair interaction is already smoothed to 0.0 at the cutoff.

The `pair_modify` table option is not relevant for this pair style.

None of the GROMACS pair styles support the `pair_modify` tail option for adding long-range tail corrections to energy and pressure, since there are no corrections for a potential that goes to 0.0 at the cutoff.

All of the GROMACS pair styles write their information to binary restart files, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

All of the GROMACS pair styles can only be used via the `pair` keyword of the `run_style respa` command. They do not support the `inner`, `middle`, `outer` keywords.

---

### 19.118.5 Restrictions

This pair style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

### 19.118.6 Related commands

`pair_coeff`

### 19.118.7 Default

none

---

### 19.119 pair_style gw command

### 19.120 pair_style gw/zbl command

---

pair_style style

- style = gw or gw/zbl

19.120.2 Examples

```plaintext
pair_style gw
pair_coeff * * SiC.gw Si C C
pair_style gw/zbl
pair_coeff * * SiC.gw.zbl C Si
```

19.120.3 Description

The gw style computes a 3-body Gao-Weber potential; similarly gw/zbl combines this potential with a modified repulsive ZBL core function in a similar fashion as implemented in the tersoff/zbl pair style.

Unfortunately the author of this contributed code has not been able to submit a suitable documentation explaining the details of the potentials. The LAMMPS developers thus have finally decided to release the code anyway with only the technical explanations. For details of the model and the parameters, please refer to the linked publication.

Only a single pair_coeff command is used with the gw and gw/zbl styles which specifies a Gao-Weber potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of GW elements to atom types

See the pair_coeff page for alternate ways to specify the path for the potential file.

As an example, imagine a file SiC.gw has Gao-Weber values for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following pair_coeff command:

```plaintext
pair_coeff * * SiC.gw Si Si Si C
```

The first 2 arguments must be ** so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the GW file. The final C argument maps LAMMPS atom type 4 to the C element in the GW file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a gw potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Gao-Weber files in the potentials directory of the LAMMPS distribution have a “.gw” suffix. Gao-Weber with ZBL files have a “.gz.zbl” suffix. The structure of the potential files is similar to other many-body potentials supported by LAMMPS. You have to refer to the comments in the files and the literature to learn more details.
19.120.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I ≠ J, where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

This pair style does not support the `pair_modify` shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

19.120.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This pair style requires the `newton` setting to be “on” for pair interactions.

The Gao-Weber potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the GW potential with any LAMMPS units, but you would need to create your own GW potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

19.120.6 Related commands

`pair_coeff`

```

- `style = harmonic/cut`

19.121. pair_style harmonic/cut command 2035
19.121.2 Examples

```
pair_style harmonic/cut
pair_coeff * * 0.2 2.0
pair_coeff 1 1 0.5 2.5
```

19.121.3 Description

Style `harmonic/cut` computes pairwise repulsive-only harmonic interactions with the formula

\[ E = k(r_c - r)^2 \quad r < r_c \]

\( r_c \) is the cutoff.

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( k \) (energy units)
- \( r_c \) (distance units)

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Accelerator packages` page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Accelerator packages` page for more instructions on how to use the accelerated styles effectively.

19.121.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I \(!=\) J, the \( k \) and \( r_c \) coefficients can be mixed. The default mix value is `geometric`. See the “pair_modify” command for details.

Since the potential is zero at and beyond the cutoff parameter by construction, there is no need to support the `pair_modify` shift or tail options for the energy and pressure of the pair interaction.

These pair styles write their information to `binary restart files`, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the `pair` keyword of the `run_style respa` command. They do not support the `inner`, `middle`, `outer` keywords.
19.121.5 Restrictions

The harmonic/cut pair style is only enabled if LAMMPS was built with the EXTRA-PAIR package. See the Build package page for more info.

pair_coeff  1 2 hbond/dreiding/morse 3 i 3.88 1.7241379 2.9 2 9 11 90
```
19.123.3 Description

The `hbond/dreiding` styles compute the Acceptor-Hydrogen-Donor (AHD) 3-body hydrogen bond interaction for the DREIDING force field, given by:

\[
E = \begin{cases} 
LJ(r) \cdot \text{Morse}(r) & r < r_{in} \\
S(r) \cdot [LJ(r) \cdot \text{Morse}(r)] & r_{in} < r < r_{out} \\
0 & r > r_{out}
\end{cases}
\]

\[
LJ(r) = AR^{-12} - BR^{-10} \cos^n \theta = \epsilon \left\{ 5 \left( \frac{\sigma}{r} \right)^{12} - 6 \left( \frac{\sigma}{r} \right)^{10} \right\} \cos^n \theta
\]

\[
\text{Morse}(r) = D_0 \left\{ \chi^2 - 2 \chi \right\} \cos^n \theta = D_0 \left\{ e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)} \right\} \cos^n \theta
\]

\[
S(r) = \frac{[r_{out}^2 - r_{in}^2]^2 [r_{out}^2 + 2r_{in}^2 - 3r_{in}^2]}{[r_{out}^2 - r_{in}^2]^3}
\]

where \( r_{in} \) is the inner spline distance cutoff, \( r_{out} \) is the outer distance cutoff, \( \theta_c \) is the angle cutoff, and \( n \) is the cosine periodicity.

Here, \( r \) is the radial distance between the donor (D) and acceptor (A) atoms and \( \theta \) is the bond angle between the acceptor, the hydrogen (H) and the donor atoms:

These 3-body interactions can be defined for pairs of acceptor and donor atoms, based on atom types. For each donor/acceptor atom pair, the third atom in the interaction is a hydrogen permanently bonded to the donor atom, e.g. in a bond list read in from a data file via the `read_data` command. The atom types of possible hydrogen atoms for each donor/acceptor type pair are specified by the `pair_coeff` command (see below).

Style `hbond/dreiding/lj` is the original DREIDING potential of (Mayo). It uses a LJ 12/10 functional for the Donor-Acceptor interactions. To match the results in the original paper, use \( n = 4 \).

Style `hbond/dreiding/morse` is an improved version using a Morse potential for the Donor-Acceptor interactions. (Liu) showed that the Morse form gives improved results for Dendrimer simulations, when \( n = 2 \).

See the Howto bioFF page for more information on the DREIDING force field.

Note: Because the Dreiding hydrogen bond potential is only one portion of an overall force field which typically includes other pairwise interactions, it is common to use it as a sub-style in a pair_style hybrid/overlay command,
where another pair style provides the repulsive core interaction between pairs of atoms, e.g. a $1/r^{12}$ Lennard-Jones repulsion.

**Note:** When using the hbond/dreiding pair styles with `pair_style hybrid/overlay`, you should explicitly define pair interactions between the donor atom and acceptor atoms, (as well as between these atoms and ALL other atoms in your system). Whenever `pair_style hybrid/overlay` is used, ordinary mixing rules are not applied to atoms like the donor and acceptor atoms because they are typically referenced in multiple pair styles. Neglecting to do this can cause difficult-to-detect physics problems.

**Note:** In the original Dreiding force field paper 1-4 non-bonded interactions ARE allowed. If this is desired for your model, use the special_bonds command (e.g. “special_bonds lj 0.0 0.0 1.0”) to turn these interactions on.

The following coefficients must be defined for pairs of eligible donor/acceptor types via the `pair_coeff` command as in the examples above.

**Note:** Unlike other pair styles and their associated `pair_coeff` commands, you do not need to specify `pair_coeff` settings for all possible I,J type pairs. Only I,J type pairs for atoms which act as joint donors/acceptors need to be specified; all other type pairs are assumed to be inactive.

**Note:** A `pair_coeff` command can be specified multiple times for the same donor/acceptor type pair. This enables multiple hydrogen types to be assigned to the same donor/acceptor type pair. For other pair_styles, if the `pair_coeff` command is re-used for the same IJ type pair, the settings for that type pair are overwritten. For the hydrogen bond potentials this is not the case; the settings are cumulative. This means the only way to turn off a previous setting, is to re-use the pair_style command and start over.

For the `hbond/dreiding/lj` style the list of coefficients is as follows:

- $K =$ hydrogen atom type = 1 to Ntypes
- donor flag = i or j
- $\epsilon$ (energy units)
- $\sigma$ (distance units)
- $n =$ exponent in formula above
- distance cutoff $r_{in}$ (distance units)
- distance cutoff $r_{out}$ (distance units)
- angle cutoff (degrees)

For the `hbond/dreiding/morse` style the list of coefficients is as follows:

- $K =$ hydrogen atom type = 1 to Ntypes
- donor flag = i or j
- $D_0$ (energy units)
- $\alpha$ (1/distance units)
- $r_0$ (distance units)
• $n$ = exponent in formula above
• distance cutoff $r_{in}$ (distance units)
• distance cutoff $r_{out}$ (distance units)
• angle cutoff (degrees)

A single hydrogen atom type $K$ can be specified, or a wild-card asterisk can be used in place of or in conjunction with the $K$ arguments to select multiple types as hydrogen atoms. This takes the form “$n$” or “*n” or “n*$” or “m*n”. See the pair_coeff command page for details.

If the donor flag is $i$, then the atom of type $I$ in the pair_coeff command is treated as the donor, and $J$ is the acceptor. If the donor flag is $j$, then the atom of type $J$ in the pair_coeff command is treated as the donor and $I$ is the donor. This option is required because the pair_coeff command requires that $I \leq J$.

$\epsilon$ and $\sigma$ are settings for the hydrogen bond potential based on a Lennard-Jones functional form. Note that sigma is defined as the zero-crossing distance for the potential, not as the energy minimum at $2^{1/6}\sigma$.

$D_0$ and $\alpha$ and $r_0$ are settings for the hydrogen bond potential based on a Morse functional form.

The last 3 coefficients for both styles are optional. If not specified, the global $n$, distance cutoff, and angle cutoff specified in the pair_style command are used. If you wish to only override the second or third optional parameter, you must also specify the preceding optional parameters.

---

Styles with a $gpu$, $intel$, $kk$, $omp$, or $opt$ suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

---

### 19.123.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support mixing. You must explicitly identify each donor/acceptor type pair.

These styles do not support the pair_modify shift option for the energy of the interactions.

The pair_modify table option is not relevant for these pair styles.

These pair styles do not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

These pair styles do not write their information to binary restart files, so pair_style and pair_coeff commands need to be re-specified in an input script that reads a restart file.

These pair styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

These pair styles tally a count of how many hydrogen bonding interactions they calculate each timestep and the hbond energy. These quantities can be accessed via the compute pair command as a vector of values of length 2.

To print these quantities to the log file (with a descriptive column heading) the following commands could be included in an input script:
compute hb all pair hbond/dreiding/lj
variable n_hbond equal c_hb[1] #number hbonds
variable E_hbond equal c_hb[2] #hbond energy
thermo_style custom step temp epair v_E_hbond

19.124 pair_style hdnnp command

19.124.1 Syntax
pair_style hdnnp cutoff keyword value ...

- cutoff = short-range cutoff of HDNNP (maximum symmetry function cutoff radius)
- zero or more keyword/value pairs may be appended
- keyword = dir or showew or showewsum or maxew or resetew or cflength or cfenergy
- value depends on the preceding keyword:
  
dir value = directory
directory = Path to HDNNP configuration files

showew value = yes or no

showewsum value = summary
  summary = Write EW summary every this many timesteps (0 turns summary off)

maxew value = threshold
  threshold = Maximum number of EWs allowed

resetew value = yes or no

19.124.2 Examples

```
pair_style hdnnp 6.35 showew yes showewsum 100 maxew 1000 resetew yes cflength 1.
  cfenergy 0.0367493254
pair_coeff * * H O

pair_style hdnnp 6.01 dir "./" showewsum 10000
pair_coeff * * S Cu NULL Cu
```

19.124.3 Description

This pair style adds an interaction based on the high-dimensional neural network potential (HDNNP) method as presented in (Behler and Parrinello 2007). HDNNPs are machine learning potentials which require careful training of neural networks prior to application in MD simulations. The pair style uses an interface to the n2p2 library (Singraber, Behler and Dellago 2019) which is available on Github here. Please see the n2p2 documentation for further details. n2p2 (and hence this pair style) is compatible with neural network potentials trained with its own tools (Singraber et al 2019) and with RuNNer.

Only a single pair_coeff command with two asterisk wild-cards is used with this pair style. Its additional arguments define the mapping of LAMMPS atom types to n2p2 elements.

```
pair_coeff * * H O
```

In the above example LAMMPS types 1 and 2 are mapped to the elements “H” and “O” in n2p2, respectively. Multiple types may map to the same element, or some types may not be mapped at all. For example, if the LAMMPS simulation has four atom types, the command

```
pair_coeff * * H H O NULL
```

maps atom types 1 and 2 to the element “H”, type 3 to “O” and type 4 is not mapped (indicated by NULL). Atoms mapped to NULL are ignored by the HDNNP calculation, i.e. they do not contribute in any way to the evaluation of HDNNP energies and forces. This may be useful in a setup with hybrid pair styles.

The mandatory pair style argument cutoff must match the short-range cutoff radius of the HDNNP. This corresponds to the maximum cutoff radius of all symmetry functions (the atomic environment descriptors of HDNNPs) used.

Note: The cutoff must be given in LAMMPS length units, even if the neural network potential has been trained using a different unit system (see remarks about the cflength and cfenergy keywords below for details).

The numeric value may be slightly larger than the actual maximum symmetry function cutoff radius (to account for rounding errors when converting units), but must not be smaller.

Use the dir keyword to specify the directory containing the HDNNP configuration files. The directory must contain input.nn with neural network and symmetry function setup, scaling.data with symmetry function scaling data and weights.???.data with weight parameters for each element.

The keyword showew can be used to turn on/off the display of extrapolation warnings (EWs) which are issued whenever a symmetry function value is out of bounds defined by minimum/maximum values in scaling.data. An extrapolation warning may look like this:

```
### NNP EXTRAPOLATION WARNING ### STRUCTURE: 0 ATOM: 119 ELEMENT: Cu SYMFUNC:...
  → 32 TYPE: 3 VALUE: 2.166E-02 MIN: 2.003E-05 MAX: 1.756E-02
```
stating that the value 2.166E-02 of symmetry function 32 of type 3 (Narrow Angular symmetry function), element Cu (see the log file for a symmetry function listing) was out of bounds (maximum in scaling.data is 1.756E-02) for atom 119. Here, the atom index refers to the LAMMPS tag (global index) and the structure index is used to print out the MPI rank the atom belongs to.

**Note:** The `showew` keyword should only be set to `yes` for debugging purposes. Extrapolation warnings may add lots of overhead as they are communicated each timestep. Also, if the simulation is run in a region where the HDNNP was not correctly trained, lots of extrapolation warnings may clog log files and the console. In a production run use `showewsum` instead.

The keyword `showewsum` can be used to get an overview of extrapolation warnings occurring during an MD simulation. The argument specifies the interval at which extrapolation warning summaries are displayed and logged. An EW summary may look like this:

```
### NNP EW SUMMARY ###
TS: 100 EW 11 EWPERSTEP 1.100E-01
```

Here, at timestep 100 the occurrence of 11 extrapolation warnings since the last summary is reported, which corresponds to an EW rate of 0.11 per timestep. Setting `showewsum` to 0 deactivates the EW summaries.

A maximum number of allowed extrapolation warnings can be specified with the `maxew` keyword. If the number of EWs exceeds the `maxew` argument the simulation is stopped. Note however that this is merely an approximate threshold since the check is only performed at the end of each timestep and each MPI process counts individually to minimize communication overhead.

The keyword `resetew` alters the behavior of the above mentioned `maxew` threshold. If `resetew` is set to `yes` the threshold is applied on a per-timestep basis and the internal EW counters are reset at the beginning of each timestep. With `resetew` set to `no` the counters accumulate EWs along the whole trajectory.

If the training of a neural network potential has been performed with different physical units for length and energy than those set in LAMMPS, it is still possible to use the potential when the unit conversion factors are provided via the `cflength` and `cfenergy` keywords. If for example, the HDNNP was parameterized with Bohr and Hartree training data and symmetry function parameters (i.e. distances and energies in “input.nn” are given in Bohr and Hartree) but LAMMPS is set to use metal units (Angstrom and eV) the correct conversion factors are:

```
cflength 1.8897261328
cfenergy 0.0367493254
```

Thus, arguments of `cflength` and `cfenergy` are the multiplicative factors required to convert lengths and energies given in LAMMPS units to respective quantities in native HDNNP units (1 Angstrom = 1.8897261328 Bohr, 1 eV = 0.0367493254 Hartree).

### 19.124.4 Mixing, shift, table, tail correction, restart, rRESPA info ###

This style does not support mixing. The `pair_coeff` command should only be invoked with asterisk wild cards (see above).

This style does not support the `pair_modify` shift, table, and tail options.

This style does not write information to binary restart files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

This style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.
19.124.5 Restrictions

This pair style is part of the ML-HDNNP package. It is only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

Please report bugs and feature requests to the n2p2 GitHub issue page.

```

19.127.3 Description

The `hybrid`, `hybrid/overlay`, and `hybrid/scaled` styles enable the use of multiple pair styles in one simulation. With the `hybrid` style, exactly one pair style is assigned to each pair of atom types. With the `hybrid/overlay` and `hybrid/scaled` styles, one or more pair styles can be assigned to each pair of atom types. The assignment of pair styles to type pairs is made via the `pair_coeff` command. The major difference between the `hybrid/overlay` and `hybrid/scaled` styles is that the `hybrid/scaled` adds a scale factor for each sub-style contribution to forces, energies and stresses. Because of the added complexity, the `hybrid/scaled` style has more overhead and thus may be slower than `hybrid/overlay`.

Here are two examples of hybrid simulations. The `hybrid` style could be used for a simulation of a metal droplet on a LJ surface. The metal atoms interact with each other via an eam potential, the surface atoms interact with each other via a lj/cut potential, and the metal/surface interaction is also computed via a lj/cut potential. The `hybrid/overlay` style could be used as in the second example above, where multiple potentials are superimposed in an additive fashion to compute the interaction between atoms. In this example, using lj/cut and coul/long together gives the same result as if the lj/cut/coul/long potential were used by itself. In this case, it would be more efficient to use the single combined potential, but in general any combination of pair potentials can be used together in to produce an interaction that is not encoded in any single pair_style file, e.g. adding Coulombic forces between granular particles. Another limitation of using the `hybrid/overlay` variant, that it does not generate lj/cut parameters for mixed atom types from a mixing rule due to restrictions discussed below.

If the `hybrid/scaled` style is used instead of `hybrid/overlay`, contributions from sub-styles are weighted by their scale factors, which may be fractional or even negative. Furthermore the scale factors may be variables that may change during a simulation. This enables switching smoothly between two different pair styles or two different parameter sets during a run.

All pair styles that will be used are listed as “sub-styles” following the `hybrid` or `hybrid/overlay` keyword, in any order. In case of the `hybrid/scaled` pair style, each sub-style is prefixed with a scale factor. The scale factor is either a floating point number or an equal style (or equivalent) variable. Each sub-style’s name is followed by its usual arguments, as illustrated in the examples above. See the doc pages of the individual pair styles for a listing and explanation of the appropriate arguments for them.

Note that an individual pair style can be used multiple times as a sub-style. For efficiency reasons this should only be done if your model requires it. E.g. if you have different regions of Si and C atoms and wish to use a Tersoff potential
for pure Si for one set of atoms, and a Tersoff potential for pure C for the other set (presumably with some third potential for Si-C interactions), then the sub-style *tersoff* could be listed twice. But if you just want to use a Lennard-Jones or other pairwise potential for several different atom type pairs in your model, then you should just list the sub-style once and use the pair_coeff command to assign parameters for the different type pairs.

**Note:** There is one exception to this option to list an individual pair style multiple times: GPU-enabled pair styles in the GPU package. This is because the GPU package currently assumes that only one instance of a pair style is being used.

In the pair_coeff commands, the name of a pair style must be added after the I,J type specification, with the remaining coefficients being those appropriate to that style. If the pair style is used multiple times in the pair_style command, then an additional numeric argument must also be specified which is a number from 1 to M where M is the number of times the sub-style was listed in the pair style command. The extra number indicates which instance of the sub-style these coefficients apply to.

For example, consider a simulation with 3 atom types: types 1 and 2 are Ni atoms, type 3 are LJ atoms with charges. The following commands would set up a hybrid simulation:

```
pair_style hybrid eam/alloy lj/cut/coul/cut 10.0 lj/cut 8.0
pair_coeff * * eam/alloy nialhjea Ni Ni NULL
pair_coeff 3 3 lj/cut/coul/cut 1.0 1.0
pair_coeff 1*2 3 lj/cut 0.8 1.3
```

As an example of using the same pair style multiple times, consider a simulation with 2 atom types. Type 1 is Si, type 2 is C. The following commands would model the Si atoms with Tersoff, the C atoms with Tersoff, and the cross-interactions with Lennard-Jones:

```
pair_style hybrid lj/cut 2.5 tersoff tersoff
dissipation
pair_coeff * * tersoff 1 Si tersoff Si NULL
pair_coeff * * tersoff 2 C tersoff NULL C
pair_coeff 1 2 lj/cut 1.0 1.5
```

It is not recommended to read pair coefficients for a hybrid style from a “Pair Coeffs” or “PairIJ Coeffs” section of a data file via the read_data command, since those sections expect a fixed number of lines, either one line per atom type or one line pair pair of atom types, respectively. When reading from a data file, the lines of the “Pair Coeffs” and “PairIJ Coeffs” are changed in the same way as the pair_coeff command, i.e. the name of the pair style to which the parameters apply must follow the atom type (or atom types), e.g.

```
Pair Coeffs
1 lj/cut/coul/cut 1.0 1.0
...
```

```
PairIJ Coeffs
1 1 lj/cut/coul/cut 1.0 1.0
...
```

Note that the pair_coeff command for some potentials such as pair_style eam/alloy includes a mapping specification of elements to all atom types, which in the hybrid case, can include atom types not assigned to the eam/alloy potential. The NULL keyword is used by many such potentials (eam/alloy, Tersoff, AIREBO, etc), to denote an atom type that will be assigned to a different sub-style.

For the hybrid style, each atom type pair IJ is assigned to exactly one sub-style. Just as with a simulation using a single pair style, if you specify the same atom type pair in a second pair_coeff command, the previous assignment will be
overwritten.

For the *hybrid/overlay* and *hybrid/scaled* styles, each atom type pair I,J can be assigned to one or more sub-styles. If you specify the same atom type pair in a second pair_coeff command with a new sub-style, then the second sub-style is added to the list of potentials that will be calculated for two interacting atoms of those types. If you specify the same atom type pair in a second pair_coeff command with a sub-style that has already been defined for that pair of atoms, then the new pair coefficients simply override the previous ones, as in the normal usage of the pair_coeff command.

E.g. these two sets of commands are the same:

```
pair_style lj/cut 2.5
pair_coeff * * 1.0 1.0
pair_coeff 2 2 1.5 0.8

pair_style hybrid/overlay lj/cut 2.5
pair_coeff * * lj/cut 1.0 1.0
pair_coeff 2 2 lj/cut 1.5 0.8
```

Coefficients must be defined for each pair of atoms types via the *pair_coeff* command as described above, or in the “Pair Coeffs” or “PairIJ Coeffs” section of the data file read by the *read_data* command, or by mixing as described below.

For all of the *hybrid*, *hybrid/overlay*, and *hybrid/scaled* styles, every atom type pair I,J (where I <= J) must be assigned to at least one sub-style via the *pair_coeff* command as in the examples above, or in the data file read by the *read_data*, or by mixing as described below. Also all sub-styles must be used at least once in a *pair_coeff* command.

**Warning:** With hybrid pair styles the use of mixing to generate pair coefficients is significantly limited compared to the individual pair styles. LAMMPS **never** performs mixing of parameters from different sub-styles, **even** if they use the same type of coefficients, e.g. contain a Lennard-Jones potential variant. Those parameters must be provided explicitly. Also for *hybrid/overlay* and *hybrid/scaled* mixing is **only** performed for pairs of atom types for which only a single pair style is assigned.

Thus it is strongly recommended to provide all mixed terms explicitly. For non-hybrid styles those could be generated and written out using the *write_coeff* command and then edited as needed to comply with the requirements for hybrid styles as explained above.

If you want there to be no interactions between a particular pair of atom types, you have 3 choices. You can assign the pair of atom types to some sub-style and use the *neigh_modify exclude type* command. You can assign it to some sub-style and set the coefficients so that there is effectively no interaction (e.g. epsilon = 0.0 in a LJ potential). Or, for *hybrid*, *hybrid/overlay*, or *hybrid/scaled* simulations, you can use this form of the pair_coeff command in your input script or the “PairIJ Coeffs” section of your data file:

```
pair_coeff 2 3 none
```

or this form in the “Pair Coeffs” section of the data file:

```
3 none
```

If an assignment to *none* is made in a simulation with the *hybrid/overlay* or *hybrid/scaled* pair style, it wipes out all previous assignments of that pair of atom types to sub-styles.

Note that you may need to use an *atom_style* hybrid command in your input script, if atoms in the simulation will need attributes from several atom styles, due to using multiple pair styles with different requirements.

Different force fields (e.g. CHARMM vs. AMBER) may have different rules for applying exclusions or weights that change the strength of pairwise non-bonded interactions between pairs of atoms that are also 1-2, 1-3, and 1-4 neighbors.
in the molecular bond topology. This is normally a global setting defined the `special_bonds` command. However, different weights can be assigned to different hybrid sub-styles via the `pair_modify special` command. This allows multiple force fields to be used in a model of a hybrid system, however, there is no consistent approach to determine parameters automatically for the interactions between atoms of the two force fields, thus this approach is only recommended when particles described by the different force fields do not mix.

Here is an example for combining CHARMM and AMBER: The global `amber` setting sets the 1-4 interactions to non-zero scaling factors and then overrides them with 0.0 only for CHARMM:

```plaintext
special_bonds amber
pair_style hybrid lj/charmm/coul/long 8.0 10.0 lj/cut/coul/long 10.0
pair_modify pair lj/charmm/coul/long special lj/coul 0.0 0.0 0.0
```

This input achieves the same effect:

```plaintext
special_bonds 0.0 0.0 0.1
pair_style hybrid lj/charmm/coul/long 8.0 10.0 lj/cut/coul/long 10.0
pair_modify pair lj/cut/coul/long special lj 0.0 0.0 0.5
pair_modify pair lj/cut/coul/long special coul 0.0 0.0 0.83333333
pair_modify pair lj/charmm/coul/long special lj/coul 0.0 0.0 0.0
```

Here is an example for combining Tersoff with OPLS/AA based on a data file that defines bonds for all atoms where -for the Tersoff part of the system - the force constants for the bonded interactions have been set to 0. Note the global settings are effectively `lj/coul 0.0 0.0 0.5` as required for OPLS/AA:

```plaintext
special_bonds lj/coul 1e-20 1e-20 0.5
pair_style hybrid tersoff lj/cut/coul/long 12.0
pair_modify pair tersoff special lj/coul 1.0 1.0 1.0
```

For use with the various `compute */tally` computes, the `pair_modify compute/tally` command can be used to selectively turn off processing of the compute tally styles, for example, if those pair styles (e.g. many-body styles) do not support this feature.

See the `pair_modify` page for details on the specific syntax, requirements and restrictions.

The potential energy contribution to the overall system due to an individual sub-style can be accessed and output via the `compute pair` command. Note that in the case of pair style `hybrid/scaled` this is the unscaled potential energy of the selected sub-style.

**Note:** Several of the potentials defined via the `pair_style` command in LAMMPS are really many-body potentials, such as Tersoff, AIREBO, MEAM, ReaxFF, etc. The way to think about using these potentials in a hybrid setting is as follows.

A subset of atom types is assigned to the many-body potential with a single `pair_coeff` command, using "**" to include all types and the NULL keywords described above to exclude specific types not assigned to that potential. If types 1,3,4 were assigned in that way (but not type 2), this means that all many-body interactions between all atoms of types 1,3,4 will be computed by that potential. Pair_style hybrid allows interactions between type pairs 2-2, 1-2, 2-3, 2-4 to be specified for computation by other pair styles. You could even add a second interaction for 1-1 to be computed by another pair style, assuming pair_style hybrid/overlay is used.

But you should not, as a general rule, attempt to exclude the many-body interactions for some subset of the type pairs within the set of 1,3,4 interactions, e.g. exclude 1-1 or 1-3 interactions. That is not conceptually well-defined for many-body interactions, since the potential will typically calculate energies and forces for small groups of atoms, e.g. 3 or 4 atoms, using the neighbor lists of the atoms to find the additional atoms in the group.
However, you can still use the pair_coeff none setting or the neigh_modify exclude command to exclude certain type pairs from the neighbor list that will be passed to a many-body sub-style. This will alter the calculations made by a many-body potential beyond the specific pairs, since it builds its list of 3-body, 4-body, etc interactions from the pair lists. You will need to think carefully as to whether excluding such pairs produces a physically meaningful result for your model.

For example, imagine you have two atom types in your model, type 1 for atoms in one surface, and type 2 for atoms in the other, and you wish to use a Tersoff potential to compute interactions within each surface, but not between the surfaces. Then either of these two command sequences would implement that model:

```
pair_style hybrid tersoff
pair_coeff * * tersoff SiC.tersoff C C
pair_coeff 1 2 none

pair_style tersoff
pair_coeff * * SiC.tersoff C C
neigh_modify exclude type 1 2
```

Either way, only neighbor lists with 1-1 or 2-2 interactions would be passed to the Tersoff potential, which means it would compute no 3-body interactions containing both type 1 and 2 atoms.

Here is another example to use 2 many-body potentials together in an overlapping manner using hybrid/overlay. Imagine you have CNT (C atoms) on a Si surface. You want to use Tersoff for Si/Si and Si/C interactions, and AIREBO for C/C interactions. Si atoms are type 1; C atoms are type 2. Something like this will work:

```
pair_style hybrid/overlay tersoff airebo 3.0
pair_coeff * * tersoff SiC.tersoff.custom Si C
pair_coeff * * airebo CH.airebo NULL C
```

Note that to prevent the Tersoff potential from computing C/C interactions, you would need to modify the SiC.tersoff potential file to turn off C/C interaction, i.e. by setting the appropriate coefficients to 0.0.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

Note: Since the hybrid, hybrid/overlay, hybrid/scaled styles delegate computation to the individual sub-styles, the suffix versions of the hybrid and hybrid/overlay styles are used to propagate the corresponding suffix to all sub-styles, if those versions exist. Otherwise the non-accelerated version will be used. The individual accelerated sub-styles are part of the GPU, KOKKOS, INTEL, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.
19.127.4 Mixing, shift, table, tail correction, restart, rRESPA info

Any pair potential settings made via the \code{pair_modify} command are passed along to all sub-styles of the hybrid potential. For atom type pairs I,J and I \neq J, if the sub-style assigned to I,I and J,J is the same, and if the sub-style allows for mixing, then the coefficients for I,J can be mixed. This means you do not have to specify a \code{pair_coeff} command for I,J since the I,J type pair will be assigned automatically to the sub-style defined for both I,I and J,J and its coefficients generated by the mixing rule used by that sub-style. For the \code{hybrid/overlay} and \code{hybrid/scaled} style, there is an additional requirement that both the I,J and J,I pairs are assigned to a single sub-style. If this requirement is not met, no I,J coeffs will be generated, even if the sub-styles support mixing, and I,J pair coefficients must be explicitly defined.

See the \code{pair_modify} command for details of mixing rules. See the \code{pair_modify} command for details of mixing rules. See the See the page for the sub-style to see if allows for mixing.

The hybrid pair styles supports the \code{pair_modify} shift, table, and tail options for an I,J pair interaction, if the associated sub-style supports it.

For the hybrid pair styles, the list of sub-styles and their respective settings are written to \code{binary restart files}, so a \code{pair_style} command does not need to specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file. Thus, \code{pair_coeff} commands need to be re-specified in the restart input script. For pair style \code{hybrid/scaled} also the names of any variables used as scale factors are restored, but not the variables themselves, so those may need to be redefined when continuing from a restart.

These pair styles support the use of the \code{inner}, \code{middle}, and \code{outer} keywords of the \code{run_style respa} command, if their sub-styles do.

19.127.5 Restrictions

When using a long-range Coulombic solver (via the \code{kspace_style} command) with a hybrid pair style, one or more sub-styles will be of the “long” variety, e.g. \code{lj/cut/coul/long} or \code{buck/coul/long}. You must insure that the short-range Coulombic cutoff used by each of these long pair styles is the same or else LAMMPS will generate an error. Pair style \code{hybrid/scaled} currently only works for non-accelerated pair styles and pair styles from the OPT package.

When using pair styles from the GPU package they must not be listed multiple times. LAMMPS will detect this and abort.

19.127.6 Related commands

\code{pair_coeff}

19.127.7 Default

\code{none}
19.128 pair_style ilp/graphene/hbn command

Accelerator Variant: ilp/graphene/hbn/opt

19.128.1 Syntax

```
pair_style [hybrid/overlay ...] ilp/graphene/hbn cutoff tap_flag
```

- `cutoff = global cutoff (distance units)`
- `tap_flag = 0/1 to turn off/on the taper function`

19.128.2 Examples

```
pair_style hybrid/overlay ilp/graphene/hbn 16.0 1
pair_coeff 1 1 coul/shield 0.70
pair_coeff 2 2 coul/shield 0.69
```

19.128.3 Description

The `ilp/graphene/hbn` style computes the registry-dependent interlayer potential (ILP) potential as described in (Leven1), (Leven2) and (Maaravi). The normals are calculated in the way as described in (Kolmogorov).

\[
E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij}
\]

\[
V_{ij} = \text{Tap}(r_{ij}) \left\{ e^{-\alpha(r_{ij}/\beta - 1)} \left[ \epsilon + f(\rho_{ij}) + f(\rho_{ji}) \right] - \frac{1}{1 + e^{-d((r_{ij}/(s_R \cdot r_{cut})) - 1)}} \cdot \frac{C_6 r_{ij}^6}{\rho_{ij}^6} \right\}
\]

\[
\rho_{ij}^2 = r_{ij}^2 - (r_{ij} \cdot n_i)^2
\]

\[
\rho_{ji}^2 = r_{ij}^2 - (r_{ij} \cdot n_j)^2
\]

\[
f(\rho) = C e^{-(\rho/\delta)^2}
\]

\[
\text{Tap}(r_{ij}) = 20 \left( \frac{r_{ij}}{R_{cut}} \right)^7 - 70 \left( \frac{r_{ij}}{R_{cut}} \right)^6 + 84 \left( \frac{r_{ij}}{R_{cut}} \right)^5 - 35 \left( \frac{r_{ij}}{R_{cut}} \right)^4 + 1
\]

Where `Tap(r_{ij})` is the taper function which provides a continuous cutoff (up to third derivative) for interatomic separations larger than `r_c` (Maaravi). The definitions of each parameter in the above equation can be found in (Leven1) and (Maaravi).

It is important to include all the pairs to build the neighbor list for calculating the normals.

**Note:** This potential (ILP) is intended for interlayer interactions between two different layers of graphene, hexagonal boron nitride (h-BN) and their hetero-junction. To perform a realistic simulation, this potential must be used in combination with intralayer potential, such as AIREBO or Tersoff potential. To keep the intralayer properties unaffected, the
interlayer interaction within the same layers should be avoided. Hence, each atom has to have a layer identifier such that atoms residing on the same layer interact via the appropriate intralayer potential and atoms residing on different layers interact via the ILP. Here, the molecule id is chosen as the layer identifier, thus a data file with the “full” atom style is required to use this potential.

The parameter file (e.g. BNCH.ILP), is intended for use with metal units, with energies in meV. Two additional parameters, \( S \) and \( r_{cut} \) are included in the parameter file. \( S \) is designed to facilitate scaling of energies. \( r_{cut} \) is designed to build the neighbor list for calculating the normals for each atom pair.

**Note:** The parameters presented in the parameter file (e.g. BNCH.ILP), are fitted with taper function by setting the cutoff equal to 16.0 Angstrom. Using different cutoff or taper function should be careful. The parameters for atoms pairs between Boron and Nitrogen are fitted with a screened Coulomb interaction \( \text{coul/shield} \). Therefore, to simulated the properties of h-BN correctly, this potential must be used in combination with the pair style \( \text{coul/shield} \).

**Note:** Four new sets of parameters of ILP for 2D layered Materials with bilayer and bulk configurations are presented in \( (\text{Ouyang1}) \) and \( (\text{Ouyang2}) \), respectively. These parameters provide a good description in both short- and long-range interaction regimes. While the old ILP parameters published in \( (\text{Leven2}) \) and \( (\text{Maaravi}) \) are only suitable for long-range interaction regime. This feature is essential for simulations in high pressure regime (i.e., the interlayer distance is smaller than the equilibrium distance). The benchmark tests and comparison of these parameters can be found in \( (\text{Ouyang1}) \) and \( (\text{Ouyang2}) \).

This potential must be used in combination with hybrid/overlay. Other interactions can be set to zero using pair_style none.

This pair style tallies a breakdown of the total interlayer potential energy into sub-categories, which can be accessed via the `compute pair` command as a vector of values of length 2. The 2 values correspond to the following sub-categories:

1. \( E_{vdW} = \text{vdW (attractive) energy} \)
2. \( E_{Rep} = \text{Repulsive energy} \)

To print these quantities to the log file (with descriptive column headings) the following commands could be included in an input script:

```plaintext
compute 0 all pair ilp/graphene/hbn
variable Evdw  equal c_0[1]
variable Erep  equal c_0[2]
thermo_style custom step temp epair v_Erep v_Evdw
```

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
19.128.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair_modify mix, shift, table, and tail options.

This pair style does not write their information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

19.128.5 Restrictions

This pair style is part of the INTERLAYER package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This pair style requires the newton setting to be on for pair interactions.

The BNCH.ILP potential file provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use this potential with any LAMMPS units, but you would need to create your BNCH.ILP potential file with coefficients listed in the appropriate units, if your simulation does not use metal units.

19.128.6 Related commands

pair_coeff, pair_none, pair_style hybrid/overlay, pair_style drip, pair_style ilp_tmd, pair_style saip_metal, pair_style pair_kolmogorov_crespi_z, pair_style pair_kolmogorov_crespi_full, pair_style pair_lebedeva_z, pair_style pair_coul_shield.

19.128.7 Default

tap_flag = 1

19.129 pair_style ilp/tmd command

Accelerator Variant: ilp/tmd/opt
19.129.1 Syntax

```
pair_style [hybrid/overlay ...] ilp/tmd cutoff tap_flag
```

- `cutoff = global cutoff (distance units)`
- `tap_flag = 0/1 to turn off/on the taper function`

19.129.2 Examples

```
pair_style hybrid/overlay ilp/tmd 16.0 1
pair_coeff * * ilp/tmd TMD.ILP Mo S S
pair_style hybrid/overlay sw/mod sw/mod ilp/tmd 16.0
pair_coeff * * sw/mod 1 tmd.sw.mod Mo S S NULL NULL NULL
pair_coeff * * sw/mod 2 tmd.sw.mod NULL NULL NULL Mo S S
pair_coeff * * ilp/tmd TMD.ILP Mo S S Mo S S
```

19.129.3 Description

The `ilp/tmd` style computes the registry-dependent interlayer potential (ILP) potential for transition metal dichalcogenides (TMD) as described in (Ouyang7).

\[
E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij} \quad V_{ij} = \text{Tap}(r_{ij}) \left\{ e^{-\alpha(r_{ij}/\beta - 1)} \left[ e + f(\rho_i) + f(\rho_j) \right] - \frac{1}{1 + e^{-d(r_{ij}/(s R \cdot r_{\text{eff}})) - 1}} \cdot C_6 \left( \frac{r_{ij}}{R_{\text{cut}}} \right)^6 \right\}
\]

Where \( \text{Tap}(r_{ij}) \) is the taper function which provides a continuous cutoff (up to third derivative) for interatomic separations larger than \( r_{\text{c}} \).

It is important to include all the pairs to build the neighbor list for calculating the normals.

**Note:** Since each MX2 (M = Mo, W and X = S, Se Te) layer contains two sub-layers of X atoms and one sub-layer of M atoms, the definition of the normal vectors used for graphene and h-BN is no longer valid for TMDs. In (Ouyang7), a new definition is proposed, where for each atom \( i \), its six nearest neighboring atoms belonging to the same sub-layer are chosen to define the normal vector \( \hat{n}_i \).

The parameter file (e.g. TMD.ILP), is intended for use with *metal units*, with energies in meV. Two additional parameters, \( S \), and \( R_{\text{cut}} \) are included in the parameter file. \( S \) is designed to facilitate scaling of energies. \( R_{\text{cut}} \) is designed to build the neighbor list for calculating the normals for each atom pair.

**Note:** The parameters presented in the parameter file (e.g. TMD.ILP), are fitted with taper function by setting the cutoff equal to 16.0 Angstrom. Using different cutoff or taper function should be careful. These parameters provide a good
description in both short- and long-range interaction regimes. This feature is essential for simulations in high pressure regime (i.e., the interlayer distance is smaller than the equilibrium distance). The benchmark tests and comparison of these parameters can be found in (Ouyang7).

This potential must be used in combination with hybrid/overlay. Other interactions can be set to zero using pair_style none.

This pair style tallies a breakdown of the total interlayer potential energy into sub-categories, which can be accessed via the compute pair command as a vector of values of length 2. The 2 values correspond to the following sub-categories:

1. \( E_{vdW} \) = vDW (attractive) energy
2. \( E_{Rep} \) = Repulsive energy

To print these quantities to the log file (with descriptive column headings) the following commands could be included in an input script:

```plaintext
compute 0 all pair ilp/tmd
variable Evdw equal c_0[1]
variable Erep equal c_0[2]
thermo_style custom step temp epair v_Erep v_Evdw
```

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 19.129.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair_modify mix, shift, table, and tail options.

This pair style does not write their information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

### 19.129.5 Restrictions

This pair style is part of the INTERLAYER package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This pair style requires the newton setting to be on for pair interactions.

The TMD.ILP potential file provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use this potential with any LAMMPS units, but you would need to create your BNCH.ILP potential file with coefficients listed in the appropriate units, if your simulation does not use metal units.
19.129.6 Related commands

19.129.7 Default

`tap_flag = 1`

19.130 pair_style kim command

19.130.1 Syntax

```
pair_style kim model
```

model = name of a KIM model (the KIM ID for models archived in OpenKIM)

19.130.2 Examples

```
pair_style kim SW_SstillingerWeber_1985_Si__MO_405512056662_005
pair_coeff * * Si
```

19.130.3 Description

This pair style is a wrapper on the Open Knowledgebase of Interatomic Models (OpenKIM) repository of interatomic potentials to enable their use in LAMMPS scripts.

The preferred interface for using interatomic models archived in OpenKIM is the `kim` command interface. That interface supports both “KIM Portable Models” (PMs) that conform to the KIM API Portable Model Interface (PMI) and can be used by any simulation code that conforms to the KIM API/PMI, and “KIM Simulator Models” (SMs) that are natively implemented within a single simulation code (like LAMMPS) and can only be used with it. The `pair_style kim` command is limited to KIM PMs. It is used by the `kim command` interface as needed.

**Note:** Since `pair_style kim` is called by `kim interactions` as needed, it is not recommended to be directly used in input scripts.

The argument `model` is the name of the KIM PM. For potentials archived in OpenKIM this is the extended KIM ID (see `kim command` for details). LAMMPS can invoke any KIM PM, however there can be incompatibilities (for example due to unit matching issues). In the event of an incompatibility, the code will terminate with an error message. Check both the LAMMPS and KIM log files for details.

Only a single `pair_coeff` command is used with the `kim` style, which specifies the mapping of LAMMPS atom types to the species supported by the KIM PM. This is done by specifying $N$ additional arguments after the `* *` in the `pair_coeff` command, where $N$ is the number of LAMMPS atom types:
• N element names = mapping of KIM elements to atom types

For example, consider a KIM PM that supports Si and C species. If the LAMMPS simulation has four atom types, where the first three are Si, and the fourth is C, the following `pair_coeff` command would be used:

```
pair_coeff * * Si Si Si C
```

The first two arguments must be `* *` so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1, 2, and 3 to Si as defined within KIM PM. The final C argument maps LAMMPS atom type 4 to C.

In addition to the usual LAMMPS error messages, the KIM library itself may generate errors, which should be printed to the screen. In this case it is also useful to check the `kim.log` file for additional error information. The file `kim.log` should be generated in the same directory where LAMMPS is running.

To download, build, and install the KIM library on your system, see the `lib/kim/README` file. Once you have done this and built LAMMPS with the KIM package installed you can run the example input scripts in `examples/kim`.

### 19.130.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the `pair_modify` mix, shift, table, and tail options.

This pair style does not write its information to binary restart files, since KIM stores the potential parameters. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

### 19.130.5 Restrictions

This pair style is part of the KIM package. See details on restrictions in `kim command`.

This current version of pair_style kim is compatible with the kim-api package version 2.0.0 and higher.

### 19.130.6 Related commands

`pair_coeff`, `kim command`

### 19.130.7 Default

none
**19.131 pair_style kolmogorov/crespi/full command**

**19.131.1 Syntax**

```plaintext
pair_style hybrid/overlay kolmogorov/crespi/full cutoff tap_flag
```

- `cutoff` = global cutoff (distance units)
- `tap_flag` = 0/1 to turn off/on the taper function

**19.131.2 Examples**

```plaintext
pair_style hybrid/overlay kolmogorov/crespi/full 20.0 0
pair_coeff * * none
pair_coeff * * kolmogorov/crespi/full CH.KC C C

pair_style hybrid/overlay rebo kolmogorov/crespi/full 16.0 1
pair_coeff * * rebo CH.rebo C H
pair_coeff * * kolmogorov/crespi/full CH_taper.KC C H
```

**19.131.3 Description**

The `kolmogorov/crespi/full` style computes the Kolmogorov-Crespi (KC) interaction potential as described in (Kolmogorov). No simplification is made,

\[
E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij}
\]

\[
V_{ij} = e^{-\lambda(r_{ij} - z_0)} \left[ C + f(\rho_{ij}) + f(\rho_{ji}) \right] - A \left( \frac{r_{ij}}{z_0} \right)^6
\]

\[
\rho_{ij}^2 = r_{ij}^2 - (r_{ij} \cdot n_i)^2
\]

\[
\rho_{ji}^2 = r_{ij}^2 - (r_{ij} \cdot n_j)^2
\]

\[
f(\rho) = e^{-\left(\frac{\rho}{\delta}\right)^2} \sum_{n=0}^{2} C_{2n} (\rho/\delta)^{2n}
\]

It is important to have a sufficiently large cutoff to ensure smooth forces and to include all the pairs to build the neighbor list for calculating the normals. Energies are shifted so that they go continuously to zero at the cutoff assuming that the exponential part of \( V_{ij} \) (first term) decays sufficiently fast. This shift is achieved by the last term in the equation for \( V_{ij} \) above. This is essential only when the taper function is turned off. The formula of taper function can be found in pair style `ilp/graphene/hbn`.

**Note:** This potential (ILP) is intended for interlayer interactions between two different layers of graphene. To perform a realistic simulation, this potential must be used in combination with intralayer potential, such as `AIREBO` or `Tersoff` potential. To keep the intralayer properties unaffected, the interlayer interaction within the same layers should be avoided. Hence, each atom has to have a layer identifier such that atoms residing on the same layer interact via the appropriate intralayer potential and atoms residing on different layers interact via the ILP. Here, the molecule id is chosen as the layer identifier, thus a data file with the “full” atom style is required to use this potential.
The parameter file (e.g. CH.KC), is intended for use with metal units, with energies in meV. Two additional parameters, $S$, and $rcut$ are included in the parameter file. $S$ is designed to facilitate scaling of energies. $rcut$ is designed to build the neighbor list for calculating the normals for each atom pair.

**Note:** Two new sets of parameters of KC potential for hydrocarbons, CH.KC (without the taper function) and CH_taper.KC (with the taper function) are presented in (Ouyang1). The energy for the KC potential with the taper function goes continuously to zero at the cutoff. The parameters in both CH.KC and CH_taper.KC provide a good description in both short- and long-range interaction regimes. While the original parameters (CC.KC) published in (Kolmogorov) are only suitable for long-range interaction regime. This feature is essential for simulations in high pressure regime (i.e., the interlayer distance is smaller than the equilibrium distance). The benchmark tests and comparison of these parameters can be found in (Ouyang1) and (Ouyang2).

This potential must be used in combination with hybrid/overlay. Other interactions can be set to zero using pair_style none.

This pair style tallies a breakdown of the total interlayer potential energy into sub-categories, which can be accessed via the compute pair command as a vector of values of length 2. The 2 values correspond to the following sub-categories:

1. $E_{vdW} = vdW$ (attractive) energy
2. $E_{Rep} = Repulsive$ energy

To print these quantities to the log file (with descriptive column headings) the following commands could be included in an input script:

```
compute 0 all pair kolmogorov/crespi/full
variable Evdw equal c_0[1]
variable Erep equal c_0[2]
thermo_style custom step temp epair v_Erep v_Evdw
```

### 19.131.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair_modify mix, shift, table, and tail options.

This pair style does not write their information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

### 19.131.5 Restrictions

This pair style is part of the INTERLAYER package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This pair style requires the newton setting to be on for pair interactions.

The CH.KC potential file provided with LAMMPS (see the potentials folder) is parameterized for metal units. You can use this pair style with any LAMMPS units, but you would need to create your own custom CC.KC potential file with all coefficients converted to the appropriate units.
19.131.6 Related commands

pair_coeff, pair_none, pair_style hybrid/overlay, pair_style drip, pair_style pair_lebedeva_z, pair_style kolmogorov/crespi/z, pair_style ilp/graphene/hbn.

19.131.7 Default

tap_flag = 0

19.132 pair_style kolmogorov/crespi/z command

19.132.1 Syntax

pair_style [hybrid/overlay ...] kolmogorov/crespi/z cutoff

19.132.2 Examples

pair_style hybrid/overlay kolmogorov/crespi/z 20.0
pair_coeff * * none
pair_coeff 1 2 kolmogorov/crespi/z CC.KC C C

pair_style hybrid/overlay rebo kolmogorov/crespi/z 14.0
pair_coeff * * rebo CH.rebo C C
pair_coeff 1 2 kolmogorov/crespi/z CC.KC C C

19.132.3 Description

The kolmogorov/crespi/z style computes the Kolmogorov-Crespi interaction potential as described in (Kolmogorov). An important simplification is made, which is to take all normals along the z-axis.

\[ E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij} \]

\[ V_{ij} = e^{-\lambda(r_{ij} - z_0)} \left[ C + f(\rho_{ij}) + f(\rho_{ji}) \right] - A \left( \frac{r_{ij}}{z_0} \right)^{-6} + A \left( \frac{\text{cutoff}}{z_0} \right)^{-6} \]

\[ \rho_{ij}^2 = \rho_{ji}^2 = x_{ij}^2 + y_{ij}^2 \quad (n_i \equiv \hat{z}) \]

\[ f(\rho) = e^{-\left(\rho/\delta\right)^2} \sum_{n=0}^2 C_{2n} (\rho/\delta)^{2n} \]

It is important to have a sufficiently large cutoff to ensure smooth forces. Energies are shifted so that they go continuously to zero at the cutoff assuming that the exponential part of \( V_{ij} \) (first term) decays sufficiently fast. This shift is achieved by the last term in the equation for \( V_{ij} \) above.
This potential is intended for interactions between two layers of graphene. Therefore, to avoid interaction between layers in multi-layered materials, each layer should have a separate atom type and interactions should only be computed between atom types of neighboring layers.

The parameter file (e.g. CC.KC), is intended for use with metal units, with energies in meV. An additional parameter, $S$, is available to facilitate scaling of energies in accordance with (vanWijk).

This potential must be used in combination with hybrid/overlay. Other interactions can be set to zero using pair_style none.

### 19.132.4 Restrictions

This fix is part of the INTERLAYER package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

### 19.132.5 Related commands

### 19.132.6 Default

none

### 19.133 pair_style lcbop command

#### 19.133.1 Syntax

```
pair_style lcbop
```

#### 19.133.2 Examples

```
pair_style lcbop
pair_coeff * * ../potentials/C.lcbop C
```
19.133.3 Description

The lcbop pair style computes the long-range bond-order potential for carbon (LCBOP) of (Los and Fasolino). See section II in that paper for the analytic equations associated with the potential.

Only a single pair_coeff command is used with the lcbop style which specifies an LCBOP potential file with parameters for specific elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of LCBOP elements to atom types

See the pair_coeff page for alternate ways to specify the path for the potential file.

As an example, if your LAMMPS simulation has 4 atom types and you want the first 3 to be C you would use the following pair_coeff command:

```
pair_coeff  *  *  C.lcbop  C  C  C  NULL
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first C argument maps LAMMPS atom type 1 to the C element in the LCBOP file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a lcbop potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

The parameters/coefficients for the LCBOP potential as applied to C are listed in the C.lcbop file to agree with the original (Los and Fasolino) paper. Thus the parameters are specific to this potential and the way it was fit, so modifying the file should be done carefully.

19.133.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair_modify mix, shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

19.133.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This pair potential requires the newton setting to be “on” for pair interactions.

The C.lcbop potential file provided with LAMMPS (see the potentials directory) is parameterized for metal units. You can use the LCBOP potential with any LAMMPS units, but you would need to create your own LCBOP potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

19.134.3 Description

The lebedeva/z pair style computes the Lebedeva interaction potential as described in (Lebedeva1) and (Lebedeva2). An important simplification is made, which is to take all normals along the z-axis.

The Lebedeva potential is intended for the description of the interlayer interaction between graphene layers. To perform a realistic simulation, this potential must be used in combination with an intralayer potential such as AIREBO or Tersoff facilitated by using pair style hybrid/overlay. To keep the intralayer properties unaffected, the interlayer interaction within the same layers should be avoided. This can be achieved by assigning different atom types to atoms of different layers (e.g. 1 and 2 in the examples above).

Other interactions can be set to zero using pair_style none.

\[
E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij} \\
V_{ij} = Be^{-\alpha(r_{ij} - z_0)} + C(1 + D_1 \rho_{ij}^2 + D_2 \rho_{ij}^4) e^{-\lambda_1 \rho_{ij}^2} e^{-\lambda_2 (z_{ij}^2 - z_0^2)} - A \left( \frac{z_0}{r_{ij}} \right)^6 + A \left( \frac{z_0}{r_c} \right)^6 \\
\rho_{ij}^2 = x_{ij}^2 + y_{ij}^2 \quad (n_i \equiv \hat{z})
\]
It is important to have a sufficiently large cutoff to ensure smooth forces. Energies are shifted so that they go continuously to zero at the cutoff assuming that the exponential part of $V_{ij}$ (first term) decays sufficiently fast. This shift is achieved by the last term in the equation for $V_{ij}$ above.

The provided parameter file (CC.Lebedeva) contains two sets of parameters.

- The first set (element name “C”) is suitable for normal conditions and is taken from (Popov1)
- The second set (element name “C1”) is suitable for high-pressure conditions and is taken from (Koziol1)

Both sets contain an additional parameter, $S$, that can be used to facilitate scaling of energies and is set to 1.0 by default.

19.134.4 Restrictions

This pair style is part of the INTERLAYER package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

```

19.135.3 Description

Style `line/lj` treats particles which are line segments as a set of small spherical particles that tile the line segment length as explained below. Interactions between two line segments, each with N1 and N2 spherical particles, are calculated as the pairwise sum of N1*N2 Lennard-Jones interactions. Interactions between a line segment with N spherical particles and a point particle are treated as the pairwise sum of N Lennard-Jones interactions. See the `pair_style lj/cut` page for the definition of Lennard-Jones interactions.

The set of non-overlapping spherical sub-particles that represent a line segment are generated in the following manner. Their size is a function of the line segment length and the specified sub-particle size for that particle type. If a line segment has a length L and is of type I, then the number of spheres N that represent the segment is calculated as N = L/sizeI, rounded up to an integer value. Thus if L is not evenly divisible by sizeI, N is incremented to include one extra sphere. The centers of the spheres are spaced equally along the line segment. Imagine N+1 equally-space points, which include the 2 end points of the segment. The sphere centers are halfway between each pair of points.

The LJ interaction between 2 spheres on different line segments (or a sphere on a line segment and a point particles) is computed with sub-particle \( \epsilon \), \( \sigma \), and cutoff values that are set by the `pair_coeff` command, as described below. If the distance between the 2 spheres is greater than the sub-particle cutoff, there is no interaction. This means that some pairs of sub-particles on 2 line segments may interact, but others may not.

For purposes of creating the neighbor list for pairs of interacting line segments or lines/point particles, a regular particle-particle cutoff is used, as defined by the cutoff setting above in the `pair_style` command or overridden with an optional argument in the `pair_coeff` command for a type pair as discussed below. The distance between the centers of 2 line segments, or the center of a line segment and a point particle, must be less than this distance (plus the neighbor skin; see the `neighbor` command), for the pair of particles to be included in the neighbor list.

**Note:** This means that a too-short value for the cutoff setting can exclude a pair of particles from the neighbor list even if pairs of their sub-particle spheres would interact, based on the sub-particle cutoff specified in the `pair_coeff` command. E.g. sub-particles at the ends of the line segments that are close to each other. Which may not be what you want, since it means the ends of 2 line segments could pass through each other. It is up to you to specify a cutoff setting that is consistent with the length of the line segments you are using and the sub-particle cutoff settings.

For style `line/lj`, the following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- sizeI (distance units)
- sizeJ (distance units)
- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)
- subcutoff (distance units)
- cutoff (distance units)

The sizeI and sizeJ coefficients are the sub-particle sizes for line particles of type I and type J. They are used to define the N sub-particles per segment as described above. These coefficients are actually stored on a per-type basis. Thus
if there are multiple pair_coeff commands that involve type I, as either the first or second atom type, you should use consistent values for sizeI or sizeJ in all of them. If you do not do this, the last value specified for sizeI will apply to all segments of type I. If typeI or typeJ refers to point particles, the corresponding sizeI or sizeJ is ignored; it can be set to 0.0.

The $\epsilon$, $\sigma$, and subcutoff coefficients are used to compute an LJ interactions between a pair of sub-particles on 2 line segments (of type I and J), or between a sub particle/point particle pair. As discussed above, the subcutoff and cutoff params are different. The latter is only used for building the neighbor list when the distance between centers of two line segments or one segment and a point particle is calculated.

The cutoff coefficient is optional. If not specified, the global cutoff is used.

19.135.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, coefficients must be specified. No default mixing rules are used.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

19.135.5 Restrictions

This style is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

Defining particles to be line segments so they participate in line/line or line/particle interactions requires the use the atom_style line command.

19.135.6 Related commands

pair_coeff, pair_style tri/lj

19.135.7 Default

none

19.136 pair_style list command

19.136.1 Syntax

pair_style list listfile cutoff keyword

- listfile = name of file with list of pairwise interactions
- cutoff = global cutoff (distance units)
- keyword = optional flag nocheck or check (default is check)
19.136.2 Examples

```plaintext
pair_style list restraints.txt 200.0
pair_coeff * *

pair_style hybrid/overlay lj/cut 1.1225 list pair_list.txt 300.0
pair_coeff * * lj/cut 1.0 1.0
pair_coeff 3* 3* list
```

19.136.3 Description

Style list computes interactions between explicitly listed pairs of atoms with the option to select functional form and parameters for each individual pair. Because the parameters are set in the list file, the pair_coeff command has no parameters (but still needs to be provided). The check and nocheck keywords enable/disable a test that checks whether all listed bonds were present and computed.

This pair style can be thought of as a hybrid between bonded, non-bonded, and restraint interactions. It will typically be used as an additional interaction within the hybrid/overlay pair style. It currently supports three interaction styles: a 12-6 Lennard-Jones, a Morse and a harmonic potential.

The format of the list file is as follows:

- one line per pair of atoms
- empty lines will be ignored
- comment text starts with a '#' character
- line syntax: ID1 ID2 style coeffs cutoff

<table>
<thead>
<tr>
<th>ID1</th>
<th>atom ID of first atom</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID2</td>
<td>atom ID of second atom</td>
</tr>
<tr>
<td>style</td>
<td>style of interaction</td>
</tr>
<tr>
<td>coeffs</td>
<td>list of coeffs</td>
</tr>
<tr>
<td>cutoff</td>
<td>cutoff for interaction (optional)</td>
</tr>
</tbody>
</table>

The cutoff parameter is optional. If not specified, the global cutoff is used.

Here is an example file:

```plaintext
# this is a comment
15 259 lj126 1.0 1.0 50.0
15 603 morse 10.0 1.2 2.0 10.0 # and another comment
18 470 harmonic 50.0 1.2 5.0
```

The style lj126 computes pairwise interactions with the formula

\[
E = 4\epsilon \left[ (\frac{\sigma}{r})^12 - (\frac{\sigma}{r})^6 \right] \quad r < r_c
\]

and the coefficients:

- \(\epsilon\) (energy units)
- \(\sigma\) (distance units)
The style *morse* computes pairwise interactions with the formula

\[ E = D_0 \left[ e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)} \right] \quad r < r_c \]

and the coefficients:

- \( D_0 \) (energy units)
- \( \alpha \) (1/distance units)
- \( r_0 \) (distance units)

The style *harmonic* computes pairwise interactions with the formula

\[ E = K(r - r_0)^2 \]

and the coefficients:

- \( K \) (energy units)
- \( r_0 \) (distance units)

Note that the usual 1/2 factor is included in \( K \).

19.136.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing since all parameters are explicit for each pair.

The *pair_modify* shift option is supported by this pair style.

The *pair_modify* table and tail options are not relevant for this pair style.

This pair style does not write its information to binary restart files, so pair_style and pair_coeff commands need to be specified in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run_style respa* command. It does not support the *inner, middle, outer* keywords.

19.136.5 Restrictions

This pair style does not use a neighbor list and instead identifies atoms by their IDs. This has two consequences: 1) The cutoff has to be chosen sufficiently large, so that the second atom of a pair has to be a ghost atom on the same node on which the first atom is local; otherwise the interaction will be skipped. You can use the *check* option to detect, if interactions are missing. 2) Unlike other pair styles in LAMMPS, an atom I will not interact with multiple images of atom J (assuming the images are within the cutoff distance), but only with the nearest image.

This style is part of the MISC package. It is only enabled if LAMMPS is build with that package. See the *Build package* page on for more info.
19.136.6 Related commands

19.136.7 Default

none

19.137 pair_style lj/cut command

Accelerator Variants: lj/cut/gpu, lj/cut/intel, lj/cut/kk, lj/cut/opt, lj/cut/omp

19.137.1 Syntax

```latex
\texttt{pair\_style style args}
```

- style = \textit{lj/cut}
- args = list of arguments for a particular style

\textit{lj/cut args} = cutoff

- cutoff = global cutoff for Lennard Jones interactions (distance units)

19.137.2 Examples

```latex
\texttt{pair\_style lj/cut 2.5}
\texttt{pair\_coeff * * 1 1}
\texttt{pair\_coeff 1 1 1.1 2.8}
```

19.137.3 Description

The \textit{lj/cut} styles compute the standard 12/6 Lennard-Jones potential, given by

\[ E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right] \quad r < r_c \]

\( r_c \) is the cutoff.

See the \textit{lj/cut/coul} styles to add a Coulombic pairwise interaction and the \textit{lj/cut/tip4p} styles to add the TIP4P water model.
19.137.4 Coefficients

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- $\epsilon$ (energy units)
- $\sigma$ (distance units)
- LJ cutoff (distance units)

Note that $\sigma$ is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum at $2^{\frac{1}{6}}\sigma$.

The last coefficient is optional. If not specified, the global LJ cutoff specified in the `pair_style` command are used.

A version of these styles with a soft core, `lj/cut/soft`, suitable for use in free energy calculations, is part of the FEP package and is documented with the `pair_style */soft` styles.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script. See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

19.137.5 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distance for all of the `lj/cut` pair styles can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

All of the `lj/cut` pair styles support the `pair_modify` shift option for the energy of the Lennard-Jones portion of the pair interaction.

All of the `lj/cut` pair styles support the `pair_modify` tail option for adding a long-range tail correction to the energy and pressure for the Lennard-Jones portion of the pair interaction.

All of the `lj/cut` pair styles write their information to binary restart files, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

The `lj/cut` pair styles support the use of the `inner`, `middle`, and `outer` keywords of the `run_style respa` command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. The other styles only support the `pair` keyword of `run_style respa`. See the `run_style` command for details.
19.137.6 Related commands

pair_coeff 1 1 1.0 1.0
```

19.138.3 Description

The lj96/cut style compute a 9/6 Lennard-Jones potential, instead of the standard 12/6 potential, given by

\[
E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^9 - \left( \frac{\sigma}{r} \right)^6 \right] \quad r < r_c
\]

\( r_c \) is the cutoff.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:
• \( \epsilon \) (energy units)
• \( \sigma \) (distance units)
• cutoff (distance units)

The last coefficient is optional. If not specified, the global LJ cutoff specified in the pair_style command is used.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 19.138.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I \(!= J\), the epsilon and sigma coefficients and cutoff distance for all of the lj/cut pair styles can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style supports the `pair_modify` shift option for the energy of the pair interaction.

The `pair_modify` table option is not relevant for this pair style.

This pair style supports the `pair_modify` tail option for adding a long-range tail correction to the energy and pressure of the pair interaction.

This pair style writes its information to binary restart files, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

This pair style supports the use of the `inner`, `middle`, and `outer` keywords of the `run_style respa` command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. See the `run_style` command for details.

### 19.138.5 Restrictions

This pair style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

19.139 pair_style lj/cubic command

Accelerator Variants: lj/cubic/gpu, lj/cubic/omp

19.139.1 Syntax

pair_style lj/cubic

19.139.2 Examples

pair_style lj/cubic
pair_coeff * * 1.0 0.8908987

19.139.3 Description

The lj/cubic style computes a truncated LJ interaction potential whose energy and force are continuous everywhere. Inside the inflection point the interaction is identical to the standard 12/6 Lennard-Jones potential. The LJ function outside the inflection point is replaced with a cubic function of distance. The energy, force, and second derivative are continuous at the inflection point. The cubic coefficient $A_3$ is chosen so that both energy and force go to zero at the cutoff distance. Outside the cutoff distance the energy and force are zero.

$$E = u_{LJ}(r) \quad r \leq r_s$$

$$= u_{LJ}(r_s) + (r - r_s)u'_{LJ}(r_s) - \frac{1}{6}A_3(r - r_s)^3 \quad r_s < r \leq r_c$$

$$= 0 \quad r > r_c$$

The location of the inflection point $r_s$ is defined by the LJ diameter, $r_s/\sigma = (26/7)^{1/6}$. The cutoff distance is defined by $r_c/r_s = 67/48$ or $r_c/\sigma = 1.737...$. The analytic expression for the the cubic coefficient $A_3r_{min}^3/\epsilon = 27.93...$ is given in the paper by Holian and Ravelo (Holian).

This potential is commonly used to study the shock mechanics of FCC solids, as in Ravelo et al. (Ravelo).

The following coefficients must be defined for each pair of atom types via the pair_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- $\epsilon$ (energy units)
- $\sigma$ (distance units)
Note that $\sigma$ is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum, which is located at $r_{\text{min}} = 2^{\frac{1}{6}} \sigma$. In the above example, $\sigma = 0.8908987$, so $r_{\text{min}} = 1.0$.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

---

### 19.139.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distance for all of the lj/cut pair styles can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

The lj/cubic pair style does not support the `pair_modify` shift option, since pair interaction is already smoothed to 0.0 at the cutoff.

The `pair_modify` table option is not relevant for this pair style.

The lj/cubic pair style does not support the `pair_modify` tail option for adding long-range tail corrections to energy and pressure, since there are no corrections for a potential that goes to 0.0 at the cutoff.

The lj/cubic pair style writes its information to binary restart files, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

The lj/cubic pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

---

### 19.139.5 Restrictions

This pair style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

pair_coeff 1 1 1.0 1.0 2.5

19.145.3 Description

The \textit{lj/cut/coul} styles compute the standard 12/6 Lennard-Jones potential, given by

\[ E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right] \quad r < r_c \]

\( r_c \) is the cutoff.

Style \textit{lj/cut/coul/cut} adds a Coulombic pairwise interaction given by

\[ E = \frac{Cq_i q_j}{\epsilon r} \quad r < r_c \]

where \( C \) is an energy-conversion constant, \( q_i \) and \( q_j \) are the charges on the 2 atoms, and \( \epsilon \) is the dielectric constant which can be set by the \textit{dielectric} command. If one cutoff is specified in the pair\_style command, it is used for both the LJ and Coulombic terms. If two cutoffs are specified, they are used as cutoffs for the LJ and Coulombic terms respectively.

Style \textit{lj/cut/coul/debye} adds an additional \( \exp() \) damping factor to the Coulombic term, given by

\[ E = \frac{Cq_i q_j}{\epsilon r} \exp(-\kappa r) \quad r < r_c \]

where \( \kappa \) is the inverse of the Debye length. This potential is another way to mimic the screening effect of a polar solvent.

Style \textit{lj/cut/coul/dsf} computes the Coulombic term via the damped shifted force model described in \textit{Fennell}, given by:

\[ E = q_i q_j \left[ \frac{\text{erfc}(\alpha r)}{r} - \frac{\text{erfc}(\alpha r_c)}{r_c} \right] + \left( \frac{\text{erfc}(\alpha r_c)}{r_c^2} + \frac{2\alpha}{\sqrt{\pi}} \text{exp}(\alpha^2 r_c^2) \right) (r - r_c) \quad r < r_c \]

where \( \alpha \) is the damping parameter and \( \text{erfc()} \) is the complementary error-function terms. This potential is essentially a short-range, spherically-truncated, charge-neutralized, shifted, pairwise \( 1/r \) summation. The potential is based on Wolf summation, proposed as an alternative to Ewald summation for condensed phase systems where charge screening causes electrostatic interactions to become effectively short-ranged. In order for the electrostatic sum to be absolutely convergent, charge neutralization within the cutoff radius is enforced by shifting the potential through placement of image charges on the cutoff sphere. Convergence can often be improved by setting \( \alpha \) to a small non-zero value.

Styles \textit{lj/cut/coul/long} and \textit{lj/cut/coul/msm} compute the same Coulombic interactions as style \textit{lj/cut/coul/cut} except that an additional damping factor is applied to the Coulombic term so it can be used in conjunction with the \textit{kspace\_style} command and its \textit{ewald} or \textit{pppm} option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

Style \textit{coul/wolf} adds a Coulombic pairwise interaction via the Wolf summation method, described in \textit{Wolf}, given by:

\[ E_i = \frac{1}{2} \sum_{j \neq i} q_i q_j \text{erfc}(\alpha r_{ij}) r_{ij} + \frac{1}{2} \sum_{j \neq i} q_i q_j \text{erf}(\alpha r_{ij}) \quad r < r_c \]

where \( \alpha \) is the damping parameter, and \( \text{erfc()} \) is the complementary error-function terms. This potential is essentially a short-range, spherically-truncated, charge-neutralized, shifted, pairwise \( 1/r \) summation. With a long enough cutoff and small enough \( \alpha \) parameter, the energy and forces calculated by the Wolf summation method approach those of the Ewald sum. So it is a means of getting effective long-range interactions with a short-range potential.
19.145.4 Coefficients

For all of the \texttt{lj/cut/coul} pair styles, the following coefficients must be defined for each pair of atoms types via the \texttt{pair_coeff} command as in the examples above, or in the data file or restart files read by the \texttt{read_data} or \texttt{read_restart} commands, or by mixing as described below:

- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)
- \texttt{cutoff1} (distance units)
- \texttt{cutoff2} (distance units)

Note that \( \sigma \) is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum at \( \frac{2}{\sqrt{16}} \sigma \).

The latter 2 coefficients are optional. If not specified, the global LJ and Coulombic cutoffs specified in the \texttt{pair_style} command are used. If only one cutoff is specified, it is used as the cutoff for both LJ and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the LJ and Coulombic cutoffs for this type pair.

For \texttt{lj/cut/coul/long} and \texttt{lj/cut/coul/msm} only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual LJ type pair. All type pairs use the same global Coulombic cutoff specified in the \texttt{pair_style} command.

A version of these styles with a soft core, \texttt{lj/cut/coul/soft} and \texttt{lj/cut/coul/long/soft}, suitable for use in free energy calculations, is part of the FEP package and is documented with the \texttt{pair_style */soft} styles.

Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \texttt{Accelerator packages} page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \texttt{Build package} page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \texttt{-suffix command-line switch} when you invoke LAMMPS, or you can use the \texttt{suffix} command in your input script.

See the \texttt{Accelerator packages} page for more instructions on how to use the accelerated styles effectively.

19.145.5 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I and J, the epsilon and sigma coefficients and cutoff distance for all of the \texttt{lj/cut} pair styles can be mixed. The default mix value is \texttt{geometric}. See the “pair_modify” command for details.

All of the \texttt{lj/cut} pair styles support the \texttt{pair_modify} shift option for the energy of the Lennard-Jones portion of the pair interaction.

The \texttt{lj/cut/coul/long} pair styles support the \texttt{pair_modify} table option since they can tabulate the short-range portion of the long-range Coulombic interaction.

All of the \texttt{lj/cut} pair styles support the \texttt{pair_modify} tail option for adding a long-range tail correction to the energy and pressure for the Lennard-Jones portion of the pair interaction.

All of the \texttt{lj/cut} pair styles write their information to \texttt{binary restart files}, so \texttt{pair_style} and \texttt{pair_coeff} commands do not need to be specified in an input script that reads a restart file.
The *lj/cut/coul/long* pair styles support the use of the inner, middle, and outer keywords of the *run_style respa* command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. The other styles only support the pair keyword of run_style respa. See the *run_style* command for details.

19.145.6 Restrictions

The *lj/cut/coul/long* and *lj/cut/coul/msm* styles are part of the KSPACE package.

The *lj/cut/coul/debye*, *lj/cut/coul/dsf*, and *lj/cut/coul/wolf* styles are part of the EXTRA-PAIR package.

These styles are only enabled if LAMMPS was built with those respective packages. See the *Build package* page for more info.

19.147.3 Description

The lj/cut/tip4p styles compute the standard 12/6 Lennard-Jones potential, given by

\[ E = 4\epsilon \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \quad r < r_c \]

where \( r_c \) is the cutoff.

They add Coulombic pairwise interactions given by

\[ E = \frac{C q_i q_j}{\epsilon r} \quad r < r_c \]

where \( C \) is an energy-conversion constant, \( q_i \) and \( q_j \) are the charges on the 2 atoms, and \( \epsilon \) is the dielectric constant which can be set by the dielectric command. If one cutoff is specified in the pair_style command, it is used for both the LJ and Coulombic terms. If two cutoffs are specified, they are used as cutoffs for the LJ and Coulombic terms respectively.

Style lj/cut/tip4p/long compute the same Coulombic interactions as style lj/cut/tip4p/cut except that an additional damping factor is applied to the Coulombic term so it can be used in conjunction with the kspace_style command and its ewald or pppm option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

The lj/cut/tip4p styles implement the TIP4P water model of (Jorgensen), which introduces a massless site located a short distance away from the oxygen atom along the bisector of the HOH angle. The atomic types of the oxygen and hydrogen atoms, the bond and angle types for OH and HOH interactions, and the distance to the massless charge site are specified as pair_style arguments. Style lj/cut/tip4p/cut uses a cutoff for Coulomb interactions; style lj/cut/tip4p/long is for use with a long-range Coulombic solver (Ewald or PPPM).

Note: For each TIP4P water molecule in your system, the atom IDs for the O and 2 H atoms must be consecutive, with the O atom first. This is to enable LAMMPS to “find” the 2 H atoms associated with each O atom. For example, if the atom ID of an O atom in a TIP4P water molecule is 500, then its 2 H atoms must have IDs 501 and 502.
See the Howto tip4p page for more information on how to use the TIP4P pair styles and lists of parameters to set. Note that the neighbor list cutoff for Coulomb interactions is effectively extended by a distance $2^*q\text{dist}$ when using the TIP4P pair style, to account for the offset distance of the fictitious charges on O atoms in water molecules. Thus it is typically best in an efficiency sense to use a LJ cutoff $\geq$ Coulombic cutoff + $2^*q\text{dist}$, to shrink the size of the neighbor list. This leads to slightly larger cost for the long-range calculation, so you can test the trade-off for your model.

### 19.147.4 Coefficients

For all of the $lj/cut$ pair styles, the following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- $\epsilon$ (energy units)
- $\sigma$ (distance units)
- LJ cutoff (distance units)

Note that $\sigma$ is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum at $2^*\sigma$.

The last coefficient is optional. If not specified, the global LJ cutoff specified in the pair_style command is used.

For $lj/cut/tip4p/cut$ and $lj/cut/tip4p/long$ only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual I,J type pair. All type pairs use the same global Coulombic cutoff specified in the pair_style command.

**Warning:** Because of how these pair styles implement the coulomb interactions by implicitly defining a fourth site for the negative charge of the TIP4P and similar water models, special care must be taken when using these pair styles with other computations that also use charges. Unless they are specially set up to also handle the implicit definition of the 4th site, results are likely incorrect. Example: compute dipole/chunk. For the same reason, when using one of these pair styles with pair_style hybrid, all coulomb interactions should be handled by a single sub-style with TIP4P support. All other instances and styles will “see” the M point charges at the position of the Oxygen atom and thus compute incorrect forces and energies. LAMMPS will print a warning when it detects one of these issues.

A version of these styles with a soft core, $lj/cut/tip4p/long/soft$, suitable for use in free energy calculations, is part of the FEP package and is documented with the pair_style */soft styles.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
19.147.5 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I != J, the epsilon and sigma coefficients and cutoff distance for all of the lj/cut pair styles can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

All of the lj/cut pair styles support the pair_modify shift option for the energy of the Lennard-Jones portion of the pair interaction.

The lj/cut/coul/long and lj/cut/tip4p/long pair styles support the pair_modify table option since they can tabulate the short-range portion of the long-range Coulombic interaction.

All of the lj/cut pair styles support the pair_modify tail option for adding a long-range tail correction to the energy and pressure for the Lennard-Jones portion of the pair interaction.

All of the lj/cut pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

The lj/cut and lj/cut/coul/long pair styles support the use of the inner, middle, and outer keywords of the run_style respa command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. The other styles only support the pair keyword of run_style respa. See the run_style command for details.

19.147.6 Restrictions

The lj/cut/tip4p/long styles are part of the KSPACE package. The lj/cut/tip4p/cut style is part of the MOLECULE package. These styles are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

```

- cutoff = global cutoff for lj/expand interactions (distance units)

19.149.2 Examples

```plaintext
pair_style lj/expand 2.5
pair_coeff * * 1.0 1.0 0.5
pair_coeff 1 1 1.0 1.0 -0.2 2.0

pair_style lj/expand/coul/long 2.5
pair_style lj/expand/coul/long 2.5 4.0
pair_coeff * * 1.0 1.0 0.5
pair_coeff 1 1 1.0 1.0 -0.2 3.0
```

19.149.3 Description

Style `lj/expand` computes a LJ interaction with a distance shifted by delta which can be useful when particles are of different sizes, since it is different that using different sigma values in a standard LJ formula:

\[ E = 4\epsilon \left[ \left( \frac{\sigma}{r - \Delta} \right)^{12} - \left( \frac{\sigma}{r - \Delta} \right)^6 \right] \quad r < r_c + \Delta \]

\( r_c \) is the cutoff which does not include the \( \Delta \) distance. I.e. the actual force cutoff is the sum of \( r_c + \Delta \).

For all of the `lj/expand` pair styles, the following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)
- \( \Delta \) (distance units)
- cutoff (distance units)

The \( \Delta \) values can be positive or negative. The last coefficient is optional. If not specified, the global LJ cutoff is used. For `lj/expand/coul/long` only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual I,J type pair. All type pairs use the same global Coulombic cutoff specified in the `pair_style` command.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.
These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

---

19.149.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I !≠ J, the epsilon, sigma, and shift coefficients and cutoff distance for this pair style can be mixed. Shift is always mixed via an arithmetic rule. The other coefficients are mixed according to the pair_modify mix value. The default mix value is geometric. See the “pair_modify” command for details.

This pair style supports the pair_modify shift option for the energy of the pair interaction.

The pair_modify table option is not relevant for this pair style.

This pair style supports the pair_modify tail option for adding a long-range tail correction to the energy and pressure of the pair interaction.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

### 19.151.3 Description

Style \( \text{lj/long/coul/long} \) computes the standard 12/6 Lennard-Jones potential:

\[
E = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right] \quad r < r_c
\]

with \( \epsilon \) and \( \sigma \) being the usual Lennard-Jones potential parameters, plus the Coulomb potential, given by:

\[
E = \frac{C q_i q_j}{\epsilon r} \quad r < r_c
\]

where \( C \) is an energy-conversion constant, \( q_i \) and \( q_j \) are the charges on the 2 atoms, \( \epsilon \) is the dielectric constant which can be set by the \text{dielectric} command, and \( r_c \) is the cutoff. If one cutoff is specified in the \text{pair_style} command, it is used for both the LJ and Coulombic terms. If two cutoffs are specified, they are used as cutoffs for the LJ and Coulombic terms respectively.

The purpose of this pair style is to capture long-range interactions resulting from both attractive \( 1/r^6 \) Lennard-Jones and Coulombic \( 1/r \) interactions. This is done by use of the \text{flag\_lj} and \text{flag\_coul} settings. The \text{In ’t Veld} paper has more details on when it is appropriate to include long-range \( 1/r^6 \) interactions, using this potential.

Style \( \text{lj/long/tip4p/long} \) implements the TIP4P water model of (Jorgensen), which introduces a massless site located a short distance away from the oxygen atom along the bisector of the HOH angle. The atomic types of the oxygen and hydrogen atoms, the bond and angle types for OH and HOH interactions, and the distance to the massless charge site are specified as \text{pair_style} arguments.

**Note:** For each TIP4P water molecule in your system, the atom IDs for the O and 2 H atoms must be consecutive, with the O atom first. This is to enable LAMMPS to “find” the 2 H atoms associated with each O atom. For example, if the atom ID of an O atom in a TIP4P water molecule is 500, then its 2 H atoms must have IDs 501 and 502.

See the \text{Howto tip4p} page for more information on how to use the TIP4P pair style. Note that the neighbor list cutoff for Coulomb interactions is effectively extended by a distance \( 2\times q\text{dist} \) when using the TIP4P pair style, to account for the offset distance of the fictitious charges on O atoms in water molecules. Thus it is typically best in an efficiency sense to use a LJ cutoff >= Coulombic cutoff + \( 2\times q\text{dist} \), to shrink the size of the neighbor list. This leads to slightly larger cost for the long-range calculation, so you can test the trade-off for your model.

If \text{flag\_lj} is set to \text{long}, no cutoff is used on the LJ \( 1/r^6 \) dispersion term. The long-range portion can be calculated by using the \text{kspace_style ewald/disp} or \text{pppm/disp} commands. The specified LJ cutoff then determines which portion of the LJ interactions are computed directly by the pair potential versus which part is computed in reciprocal space via the Kspace style. If \text{flag\_lj} is set to \text{cut}, the LJ interactions are simply cutoff, as with \text{pair_style lj/cut}.

If \text{flag\_coul} is set to \text{long}, no cutoff is used on the Coulombic interactions. The long-range portion can be calculated by using any of several \text{kspace_style} command options such as \text{pppm} or \text{ewald}. Note that if \text{flag\_lj} is also set to long, then the \text{ewald} or \text{pppm/disp} Kspace style needs to be used to perform the long-range calculations for both the LJ and Coulombic interactions. If \text{flag\_coul} is set to \text{off}, Coulombic interactions are not computed.

The following coefficients must be defined for each pair of atoms types via the \text{pair_coeff} command as in the examples above, or in the data file or restart files read by the \text{read_data} or \text{read_restart} commands, or by mixing as described below:

- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)
- cutoff1 (distance units)
- cutoff2 (distance units)
Note that sigma is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum at $2^{(1/6)}$ sigma.

The latter 2 coefficients are optional. If not specified, the global LJ and Coulombic cutoffs specified in the pair_style command are used. If only one cutoff is specified, it is used as the cutoff for both LJ and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the LJ and Coulombic cutoffs for this type pair.

Note that if you are using flag_lj set to long, you cannot specify a LJ cutoff for an atom type pair, since only one global LJ cutoff is allowed. Similarly, if you are using flag_coul set to long, you cannot specify a Coulombic cutoff for an atom type pair, since only one global Coulombic cutoff is allowed.

For lj/long/tip4p/long only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual IJ type pair. All type pairs use the same global Coulombic cutoff specified in the pair_style command.

A version of these styles with a soft core, lj/cut/soft, suitable for use in free energy calculations, is part of the FEP package and is documented with the pair_style */soft styles. The version with soft core is only available if LAMMPS was built with that package. See the Build package page for more info.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 19.151.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I != J, the epsilon and sigma coefficients and cutoff distance for all of the lj/long pair styles can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

These pair styles support the pair_modify shift option for the energy of the Lennard-Jones portion of the pair interaction, assuming flag_lj is cut.

These pair styles support the pair Modify table and table/disp options since they can tabulate the short-range portion of the long-range Coulombic and dispersion interactions.

These pair styles do not support the pair_modify tail option for adding a long-range tail correction to the Lennard-Jones portion of the energy and pressure.

These pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

The pair lj/long/coul/long styles support the use of the inner, middle, and outer keywords of the run_style respa command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. See the run_style command for details.
19.151.5 Restrictions

These styles are part of the KSPACE package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

19.151.6 Related commands

pair_coeff

19.151.7 Default

none

19.152 pair_style lj/relres command

Accelerator Variants: lj/relres/omp

19.152.1 Syntax

pair_style lj/relres Rsi Rso Rci Rco

- Rsi = inner switching cutoff between the fine-grained and coarse-grained potentials (distance units)
- Rso = outer switching cutoff between the fine-grained and coarse-grained potentials (distance units)
- Rci = inner cutoff beyond which the force smoothing for all interactions is applied (distance units)
- Rco = outer cutoff for all interactions (distance units)

19.152.2 Examples

pair_style lj/relres 4.0 5.0 8.0 10.0
pair_coeff 1 1 0.5 1.0 1.5 1.1
pair_coeff 2 2 0.5 1.0 0.0 0.0 3.0 3.5 6.0 7.0

19.152.3 Description

Pair style lj/relres computes a LJ interaction using the Relative Resolution (RelRes) framework which applies a fine-grained (FG) potential between near neighbors and a coarse-grained (CG) potential between far neighbors.
This approach can improve the computational efficiency by almost an order of magnitude, while maintaining the correct static and dynamic behavior of a reference system. The energy expression is given by:

\[
E = \begin{cases} 
4\epsilon_{FG} \left( \frac{\sigma_{FG}}{r} \right)^{12} - \left( \frac{\sigma_{FG}}{r} \right)^{6} - \Gamma_{si}, & \text{if } r < r_{si}, \\
\sum_{m=0}^{4} \gamma_{sm} (r - r_{si})^{m} - \Gamma_{so}, & \text{if } r_{si} \leq r < r_{so}, \\
4\epsilon_{CG} \left( \frac{\sigma_{CG}}{r} \right)^{12} - \left( \frac{\sigma_{CG}}{r} \right)^{6} - \Gamma_{c}, & \text{if } r_{so} \leq r < r_{ci}, \\
\sum_{m=0}^{4} \gamma_{cm} (r - r_{ci})^{m} - \Gamma_{co}, & \text{if } r_{ci} \leq r < r_{co}, \\
0, & \text{if } r \geq r_{co}.
\end{cases}
\]

The FG parameters of the LJ potential \( \epsilon_{FG} \) and \( \sigma_{FG} \) are applied up to the inner switching cutoff, \( r_{si} \), while the CG parameters of the LJ potential \( \epsilon_{CG} \) and \( \sigma_{CG} \) are applied beyond the outer switching cutoff, \( r_{so} \). Between \( r_{si} \) and \( r_{so} \), a polynomial smoothing function is applied so that the force and its derivative are continuous between the FG and CG potentials. An analogous smoothing function is applied between the inner and outer cutoffs \( r_{ci} \) and \( r_{co} \). The offsets \( \Gamma_{si} \), \( \Gamma_{so} \), and \( \Gamma_{c} \) ensure the continuity of the energy over the entire domain. The corresponding polynomial coefficients \( \gamma_{sm} \) and \( \gamma_{cm} \), as well as the offsets are automatically computed by LAMMPS.

**Note:** Energy and force resulting from this methodology can be plotted via the `pair_write` command.

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as will be described below:

- \( \epsilon_{FG} \) (energy units)
- \( \sigma_{FG} \) (distance units)
- \( \epsilon_{CG} \) (energy units)
- \( \sigma_{CG} \) (distance units)

Additional parameters can be defined to specify different \( r_{si} \), \( r_{so} \), \( r_{ci} \), \( r_{co} \) for a particular set of atom types:

- \( r_{si} \) (distance units)
- \( r_{so} \) (distance units)
- \( r_{ci} \) (distance units)
- \( r_{co} \) (distance units)

These parameters are optional, and they are used to override the global cutoffs as defined in the `pair_style` command. If not specified, the global values for \( r_{si} \), \( r_{so} \), \( r_{ci} \), and \( r_{co} \) are used. If this override option is employed, all four arguments must be specified.

Here are some guidelines for using the `pair_style lj/relres` command.

In general, RelRes focuses on the speedup of pairwise interactions between all LJ sites. Importantly, it works with any settings and flags (e.g., `special_bonds` settings and `newton` flags) that can be used in a molecular simulation with the conventional LJ potential. In particular, all intramolecular topology with its energetics (i.e., bonds, angles, etc.) remains unaltered.

At the most basic level in the RelRes framework, all sites are mapped into clusters. Each cluster is just a collection of sites bonded together (the bonds themselves are not part of the cluster). In general, a molecule may be comprised of several clusters, and preferably, no two sites in a cluster are separated by more than two bonds. There are two categories of sites in RelRes: "hybrid" sites embody both FG and CG models, while "ordinary" sites embody just FG characteristics with no CG features. A given cluster has a single hybrid site (typically its central site) and several
ordinary sites (typically its peripheral sites). Notice that while clusters are necessary for the RelRes parameterization (discussed below), they are not actually defined in LAMMPS. Besides, the total number of sites in the cluster are called the “mapping ratio”, and this substantially impacts the computational efficiency of RelRes: For a mapping ratio of 3, the efficiency factor is around 4, and for a mapping ratio of 5, the efficiency factor is around 5 (Chaimovich2).

The flexibility of LAMMPS allows placing any values for the LJ parameters in the input script. However, here are the optimal recommendations for the RelRes parameters, which yield the correct structural and thermal behavior in a system of interest (Chaimovich1). One must first assign a complete set of parameters for the FG interactions that are applicable to all atom types. Regarding the parameters for the CG interactions, the rules rely on the site category (if it is a hybrid or an ordinary site). For atom types of ordinary sites, $\epsilon^{CG}$ must be set to 0 (zero) while the specific value of $\sigma^{CG}$ is irrelevant. For atom types of hybrid sites, the CG parameters should be generally calculated using the following equations:

$$\sigma^{CG}_I = \left( \frac{\sum_{\alpha \in A} \sqrt{\rho^{FG}_\alpha (\sigma^{FG}_\alpha)^2}}{(\sum_{\alpha \in A} \sqrt{\rho^{FG}_\alpha (\sigma^{FG}_\alpha)^6})^{1/3}} \right)^{1/2} \text{ and } \epsilon^{CG}_I = \left( \frac{\sum_{\alpha \in A} \sqrt{\rho^{FG}_\alpha (\sigma^{FG}_\alpha)^2}}{(\sum_{\alpha \in A} \sqrt{\rho^{FG}_\alpha (\sigma^{FG}_\alpha)^6})^{2/3}} \right)^{4/3}$$

where $I$ is an atom type of a hybrid site of a particular cluster $A$, and corresponding with this cluster, the summation proceeds over all of its sites $\alpha$. These equations are derived from the monopole term in the underlying Taylor series, and they are indeed relevant only if geometric mixing is applicable for the FG model; if this is not the case, Ref. (Chaimovich2) discusses the alternative formula, and in such a situation, the pair_coeff command should be explicitly used for all combinations of atom types $I \neq J$.

The switching distance (the midpoint between inner and outer switching cutoffs) is another crucial factor in RelRes: decreasing it improves the computational efficiency, yet if it is too small, the molecular simulations may not capture the system behavior correctly. As a rule of thumb, the switching distance should be approximately $\sim 1.5\sigma$ (Chaimovich1); recommendations can be found in Ref. (Chaimovich2). Regarding the switching smoothing zone, $\sim 0.1\sigma$ is recommended; if desired, smoothing can be eliminated by setting the inner switching cutoff, $r_{si}$, equal to the outer switching cutoff, $r_{so}$ (the same is true for the other cutoffs $r_{ci}$ and $r_{co}$).

As an example, imagine that in your system, a molecule is comprised just of one cluster such that one atom type (#1) is associated with its hybrid site, and another atom type (#2) is associated with its ordinary sites (in total, there are 2 atom types). If geometric mixing is applicable, the following commands should be used:

```
pair_style lj/relres Rsi Rso Rci Rco
pair_coeff 1 1 epsilon_FG1 sigma_FG1 epsilon_CG1 sigma_CG1
pair_coeff 2 2 epsilon_FG2 sigma_FG2 0.0 0.0
pair_modify shift yes
```

In a more complex situation, there may be two distinct clusters in a system (these two clusters may be on same molecule or on different molecules), each with its own switching cutoffs. If there are still two atom types in each cluster as in the earlier example, the commands should be:

```
pair_style lj/relres Rsi Rso Rci Rco
pair_coeff 1 1 epsilon_FG1 sigma_FG1 epsilon_CG1 sigma_CG1 Rsil Rsol Rci Rco
pair_coeff 2 2 epsilon_FG2 sigma_FG2 0.0 0.0 Rsil Rsol Rci Rco
pair_coeff 3 3 epsilon_FG3 sigma_FG3 epsilon_CG3 sigma_CG3
pair_coeff 4 4 epsilon_FG4 sigma_FG4 0.0 0.0
pair_modify shift yes
```

In this example, the switching cutoffs for the first cluster (atom types 1 and 2) is defined explicitly in the pair_coeff command which overrides the global values, while the second cluster (atom types 3 and 4) uses the global definition from the pair_style command. The emphasis here is that the atom types that belong to a specific cluster should have the same switching/cutoff arguments.
In the case that geometric mixing is not applicable, for simulating the system from the previous example, we recommend using the following commands:

```
pair_style lj/relres Rsi Rso Rci Rco
pair_coeff 1 1 epsilon_FG1 sigma_FG1 epsilon_CG1 sigma_CG1 Rsi1 Rso1 Rci Rco
pair_coeff 1 2 epsilon_FG12 sigma_FG12 0.0 0.0 Rsi1 Rso1 Rci Rco
pair_coeff 1 3 epsilon_FG13 sigma_FG13 epsilon_CG13 sigma_CG13 Rsi13 Rso13 Rci Rco
pair_coeff 1 4 epsilon_FG14 sigma_FG14 0.0 0.0 Rsi13 Rso13 Rci Rco
pair_coeff 2 2 epsilon_FG2 sigma_FG2 0.0 0.0 Rsi1 Rso1 Rci Rco
pair_coeff 2 3 epsilon_FG23 sigma_FG23 0.0 0.0 Rsi13 Rso13 Rci Rco
pair_coeff 2 4 epsilon_FG24 sigma_FG24 0.0 0.0 Rsi13 Rso13 Rci Rco
pair_coeff 3 3 epsilon_FG3 sigma_FG3 epsilon_CG3 sigma_CG3
pair_coeff 3 4 epsilon_FG34 sigma_FG34 0.0 0.0
pair_coeff 4 4 epsilon_FG4 sigma_FG4 0.0 0.0
pair_modify shift yes
```

Notice that the CG parameters are mixed only for interactions between atom types associated with hybrid sites, and that the cutoffs are mixed on the cluster basis.

More examples can be found in the `examples/relres` folder.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the [Accelerator packages](https://www.lammps.org/doc/getting-started/accelerator.html) page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the [Build package](https://www.lammps.org/doc/getting-started/build.html) page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the [Accelerator packages](https://www.lammps.org/doc/getting-started/accelerator.html) page for more instructions on how to use the accelerated styles effectively.

### 19.152.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs $I, J$ with $I \neq J$, the $\epsilon_{FG}, \sigma_{FG}, \epsilon_{CG}, \sigma_{CG}, r_{si}, r_{so}, r_{ci},$ and $r_{co}$ parameters for this pair style can be mixed, if not defined explicitly. All parameters are mixed according to the `pair_modify mix` option. The default mix value is `geometric`, and it is recommended to use with this `lj/relres` style. See the “pair_modify” command for details.

This pair style supports the `pair_modify shift` option for the energy of the pair interaction. It is recommended to set this option to `yes`. Otherwise, the offset $\Gamma_c$ is set to zero. Constants $\Gamma_{si}$ and $\Gamma_{so}$ are not impacted by this option.

The `pair_modify table` option is not relevant for this pair style.

This pair style does not support the `pair_modify tail` option for adding long-range tail corrections to energy and pressure, since the energy of the pair interaction is smoothed to 0.0 at the cutoff.

This pair style writes its information to `binary restart files`, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, or `outer` keywords.
19.152.5 Restrictions

This pair style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

19.152.6 Related commands

pair_coeff

19.152.7 Default

none

19.153 pair_style lj/smooth command

Accelerator Variants: lj/smooth/gpu, lj/smooth/omp

19.153.1 Syntax

pair_style lj/smooth Rin Rc

- Rin = inner cutoff beyond which force smoothing will be applied (distance units)
- Rc = outer cutoff for lj/smooth interactions (distance units)

19.153.2 Examples

pair_style lj/smooth 8.0 10.0
pair_coeff * * 10.0 1.5
pair_coeff 1 1 20.0 1.3 7.0 9.0

19.153.3 Description

Style lj/smooth computes a LJ interaction with a force smoothing applied between the inner and outer cutoff.

\[ E = 4\epsilon \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \] \hspace{1cm} r < r_{in}

\[ F = C_1 + C_2 (r - r_{in}) + C_3 (r - r_{in})^2 + C_4 (r - r_{in})^3 \] \hspace{1cm} r_{in} < r < r_c

The polynomial coefficients C1, C2, C3, C4 are computed by LAMMPS to cause the force to vary smoothly from the inner cutoff \( r_{in} \) to the outer cutoff \( r_c \).

At the inner cutoff the force and its first derivative will match the non-smoothed LJ formula. At the outer cutoff the force and its first derivative will be 0.0. The inner cutoff cannot be 0.0.
Note: this force smoothing causes the energy to be discontinuous both in its values and first derivative. This can lead to poor energy conservation and may require the use of a thermostat. Plot the energy and force resulting from this formula via the pair_write command to see the effect.

The following coefficients must be defined for each pair of atom types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- $\epsilon$ (energy units)
- $\sigma$ (distance units)
- $r_{in}$ (distance units)
- $r_c$ (distance units)

The last 2 coefficients are optional inner and outer cutoffs. If not specified, the global values for $r_{in}$ and $r_c$ are used.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

19.153.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I != J, the epsilon, sigma, Rin coefficients and the cutoff distance for this pair style can be mixed. Rin is a cutoff value and is mixed like the cutoff. The other coefficients are mixed according to the pair_modify mix option. The default mix value is geometric. See the “pair_modify” command for details.

This pair style supports the pair_modify shift option for the energy of the pair interaction.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure, since the energy of the pair interaction is smoothed to 0.0 at the cutoff.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.
19.153.5 Restrictions

This pair style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

19.153.6 Related commands

pair_coeff, pair lj/smooth/linear

19.153.7 Default

none

19.154 pair_style lj/smooth/linear command

Accelerator Variants: lj/smooth/linear/omp

19.154.1 Syntax

```
pair_style lj/smooth/linear cutoff
```

- cutoff = global cutoff for Lennard-Jones interactions (distance units)

19.154.2 Examples

```
pair_style lj/smooth/linear 2.5
pair_coeff * * 1.0 1.0
pair_coeff 1 1 0.3 3.0 9.0
```

19.154.3 Description

Style lj/smooth/linear computes a truncated and force-shifted LJ interaction (aka Shifted Force Lennard-Jones) that combines the standard 12/6 Lennard-Jones function and subtracts a linear term based on the cutoff distance, so that both, the potential and the force, go continuously to zero at the cutoff $R_c$ (Toxvaerd):

$$
\phi (r) = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right]
$$

$$
E (r) = \phi (r) - \phi (R_c) - (r - R_c) \left. \frac{d\phi}{dr} \right|_{r=R_c} \quad r < R_c
$$

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- $\epsilon$ (energy units)
- $\sigma$ (distance units)
• cutoff (distance units)

The last coefficient is optional. If not specified, the global LJ cutoff specified in the pair_style command is used.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script. See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

### 19.154.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I ! = J, the epsilon and sigma coefficients and cutoff distance can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the `pair_modify` shift option for the energy of the pair interaction, since it goes to 0.0 at the cutoff by construction.

The `pair_modify` table option is not relevant for this pair style.

This pair style does not support the `pair_modify` tail option for adding long-range tail corrections to energy and pressure, since the energy of the pair interaction is smoothed to 0.0 at the cutoff.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

### 19.154.5 Restrictions

This pair style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

19.156.3 Description

The *lj/switch3/coulgauss* style evaluates the LJ vdW potential

\[ E = 4\epsilon \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \]

The *mm3/switch3/coulgauss/long* style evaluates the MM3 vdW potential (Allinger)

\[ E = \epsilon_{ij} \left[ -2.25 \left( \frac{r_{v,ij}}{r_{ij}} \right)^6 + 1.84(10)^5 \exp \left[ -12.0r_{ij}/r_{v,ij} \right] \right] S_3(r_{ij}) \]

\[ r_{v,ij} = r_{v,i} + r_{v,j} \]

\[ \epsilon_{ij} = \sqrt{\epsilon_i \epsilon_j} \]

Both potentials go smoothly to zero at the cutoff \( r_c \) as defined by the switching function

\[ S_3(r) = \begin{cases} 
1 & \text{if } r < r_c - w \\
3x^2 - 2x^3 & \text{if } r < r_c \text{ with } x = \frac{r - r_c}{w} \\
0 & \text{if } r \geq r_c 
\end{cases} \]

where \( w \) is the width defined in the arguments. This potential is combined with Coulomb interaction between Gaussian charge densities:

\[ E = \frac{q_i q_j \text{erf} \left( r / \sqrt{\gamma_1^2 + \gamma_2^2} \right)}{\epsilon r_{ij}} \]

where \( q_i \) and \( q_j \) are the charges on the 2 atoms, \( \epsilon \) is the dielectric constant which can be set by the *dielectric* command, \( \gamma_1 \) and \( \gamma_2 \) are the widths of the Gaussian charge distribution and erf() is the error-function. This style has to be used in conjunction with the *kspace_style* command.

If one cutoff is specified it is used for both the vdW and Coulomb terms. If two cutoffs are specified, the first is used as the cutoff for the vdW terms, and the second is the cutoff for the Coulombic term.

The following coefficients must be defined for each pair of atoms types via the *pair_coeff* command as in the examples above, or in the data file or restart files read by the *read_data* or *read_restart* commands:

- \( \epsilon \) (energy)
- \( \sigma \) (distance)
- \( \gamma \) (distance)

19.156.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs \( I,J \) and \( I \neq J \), the epsilon and sigma coefficients and cutoff distance for all of the lj/long pair styles can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

Shifting the potential energy is not necessary because the switching function ensures that the potential is zero at the cut-off.

These pair styles support the *pair_modify* table and options since they can tabulate the short-range portion of the long-range Coulombic interactions.

These pair styles do not support the *pair_modify* tail option for adding a long-range tail correction to the Lennard-Jones portion of the energy and pressure.
These pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file. These pair styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

19.156.5 Restrictions

These styles are part of the YAFF package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

19.156.6 Related commands

pair_coeff

19.156.7 Default

none

19.157 pair_style local/density command

19.157.1 Syntax

pair_style style arg

• style = local/density
• arg = name of file containing tabulated values of local density and the potential

19.157.2 Examples

pair_style local/density benzene_water.localdensity.table
pair_style hybrid/overlay table spline 500 local/density
pair_coeff * * local/density benzene_water.localdensity.table

19.157.3 Description

The local density (LD) potential is a mean-field manybody potential, and, in some way, a generalization of embedded atom models (EAM). The name “local density potential” arises from the fact that it assigns an energy to an atom depending on the number of neighboring atoms of a given type around it within a predefined spherical volume (i.e., within the cutoff). The bottom-up coarse-graining (CG) literature suggests that such potentials can be widely useful in capturing effective multibody forces in a computationally efficient manner and thus improve the quality of CG models of implicit solvation (Sanyal) and phase-segregation in liquid mixtures (Sanyal2), and provide guidelines to determine the extent of manybody correlations present in a CG model (Rosenberger). The LD potential in LAMMPS is primarily intended to be used as a corrective potential over traditional pair potentials in bottom-up CG models via hybrid/overlay pair style with other explicit pair interaction terms (e.g., tabulated, Lennard-Jones, Morse etc.).
the LD potential is not a pair potential per se, it is implemented simply as a single auxiliary file with all specifications that will be read upon initialization.

**Note:** Thus when used as the only interaction in the system, there is no corresponding pair_coeff command and when used with other pair styles using the hybrid/overlay option, the corresponding pair_coeff command must be supplied *as placeholders for the atom types.

---

**System with a single CG atom type:**

A system of a single atom type (e.g., LJ argon) with a single local density (LD) potential would have an energy given by:

\[
U_{LD} = \sum_i F(\rho_i)
\]

where \(\rho_i\) is the LD at atom \(i\) and \(F(\rho)\) is similar in spirit to the embedding function used in EAM potentials. The LD at atom \(i\) is given by the sum

\[
\rho_i = \sum_{j \neq i} \varphi(r_{ij})
\]

where \(\varphi\) is an indicator function that is one at \(r=0\) and zero beyond a cutoff distance \(R_2\). The choice of the functional form of \(\varphi\) is somewhat arbitrary, but the following piecewise cubic function has proven sufficiently general: \((Sanyal1)\), \((Sanyal2)\) (Rosenberger)

\[
\varphi(r) = \begin{cases} 
1 & r \leq R_1 \\
0 & r \geq R_2 \\
c_0 + c_2r^2 + c_4r^4 + c_6r^6 & r \in (R_1, R_2)
\end{cases}
\]

The constants \(c\) are chosen so that the indicator function smoothly interpolates between 1 and 0 between the distances \(R_1\) and \(R_2\), which are called the inner and outer cutoffs, respectively. Thus \(\varphi\) satisfies \(\varphi(R_1) = 1\), \(\varphi(R_2) = \varphi'(r_{R_1}) = \varphi''(r_{R_2}) = 0\). The embedding function \(F(\rho)\) may or may not have a closed-form expression. To maintain generality, it is practically represented with a spline-interpolated table over a predetermined range of \(\rho\). Outside of that range it simply adopts zero values at the endpoints.

It can be shown that the total force between two atoms due to the LD potential takes the form of a pair force, which motivates its designation as a LAMMPS pair style. Please see \((Sanyal1)\) for details of the derivation.

---

**Systems with arbitrary numbers of atom types:**

The potential is easily generalized to systems involving multiple atom types:

\[
U_{LD} = \sum_i a_\alpha F(\rho_i)
\]

with the LD expressed as

\[
\rho_i = \sum_{j \neq i} b_\beta \varphi(r_{ij})
\]

where \(\alpha\) gives the type of atom \(i\), \(\beta\) the type of atom \(j\), and the coefficients \(a\) and \(b\) filter for atom types as specified by the user. \(a\) is called the central atom filter as it determines to which atoms the potential applies; \(a_\alpha = 1\) if the LD potential applies to atom type \(\alpha\) else zero. On the other hand, \(b\) is called the neighbor atom filter because it specifies which atom types to use in the calculation of the LD; \(b_\beta = 1\) if atom type \(\beta\) contributes to the LD and zero otherwise.
Note: Note that the potentials need not be symmetric with respect to atom types, which is the reason for two distinct sets of coefficients $a$ and $b$. An atom type may contribute to the LD but not the potential, or to the potential but not the LD. Such decisions are made by the user and should (ideally) be motivated on physical grounds for the problem at hand.

General form for implementation in LAMMPS:

Of course, a system with many atom types may have many different possible LD potentials, each with their own atom type filters, cutoffs, and embedding functions. The most general form of this potential as implemented in the pair_style local/density is:

$$U_{LD} = \sum_k U_{LD}^{(k)} = \sum_i \left[ \sum_k a_{\alpha}^{(k)} F^{(k)} \left( \rho_i^{(k)} \right) \right]$$

where, $k$ is an index that spans the (arbitrary) number of applied LD potentials $N_{LD}$. Each LD is calculated as before with:

$$\rho_i^{(k)} = \sum_j b_{\beta}^{(k)} \varphi^{(k)}(r_{ij})$$

The superscript on the indicator function phi simply indicates that it is associated with specific values of the cutoff distances $R_1(k)$ and $R_2(k)$. In summary, there may be $N_{LD}$ distinct LD potentials. With each potential type $(k)$, one must specify:

- the inner and outer cutoffs as $R_1$ and $R_2$
- the central type filter $a(k)$, where $k = 1,2,\ldots N_{LD}$
- the neighbor type filter $b(k)$, where $k = 1,2,\ldots N_{LD}$
- the LD potential function $F(k)(\rho)$, typically as a table that is later spline-interpolated

Tabulated input file format:

| Line 1: | comment or blank (ignored) |
| Line 2: | comment or blank (ignored) |
| Line 3: | $N_{LD}$ $N_{rho}$ (# of LD potentials and # of tabulated values, single space separated) |
| Line 4: | blank (ignored) |
| Line 5: | $R_1(k)$ $R_2(k)$ (lower and upper cutoffs, single space separated) |
| Line 6: | central-types (central atom types, single space separated) |
| Line 7: | neighbor-types (neighbor atom types single space separated) |
| Line 8: | $\rho_{min}$ $\rho_{max}$ $drho$ (min, max and diff. in tabulated rho values, single space separated) |
| Line 9: | $F(k)(\rho_{min} + 0.drho)$ |
| Line 10: | $F(k)(\rho_{min} + 1.drho)$ |
| Line 11: | $F(k)(\rho_{min} + 2.drho)$ |
| ... | |
| Line 9+$N_{rho}$: | $F(k)(\rho_{min} + N_{rho} . drho)$ |
| Line 10+$N_{rho}$: | blank (ignored) |
Block 3
Block N_LD

Lines 5 to 9+N_rho constitute the first block. Thus the input file is separated (by blank lines) into N_LD blocks each
representing a separate LD potential and each specifying its own upper and lower cutoffs, central and neighbor atoms,
and potential. In general, blank lines anywhere are ignored.

19.157.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support automatic mixing. For atom type pairs α, β and α != β, even if LD potentials of type
(α, α) and (β, β) are provided, you will need to explicitly provide LD potential types (α, β) and (β, α) if need be (Here,
the notation (α, β) means that α is the central atom to which the LD potential is applied and β is the neighbor atom
which contributes to the LD potential on α).

This pair style does not support the pair_modify shift, table, and tail options.

The local/density pair style does not write its information to binary restart files, since it is stored in tabulated potential
files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

19.157.5 Restrictions

The local/density pair style is a part of the MANYBODY package. It is only enabled if LAMMPS was built with that
package. See the Build package page for more info.

19.158 pair_style lubricate command

Accelerator Variants: lubricate/omp

19.159 pair_style lubricate/poly command

Accelerator Variants: lubricate/poly/omp

19.159.1 Syntax

```
pair_style style mu flaglog flagfld cutinner cutoff flagHI flagVF
```

- `style` = lubricate or lubricate/poly
- `mu` = dynamic viscosity (dynamic viscosity units)
- `flaglog` = 0/1 to exclude/include log terms in the lubrication approximation
- `flagfld` = 0/1 to exclude/include Fast Lubrication Dynamics (FLD) effects
- `cutinner` = inner cutoff distance (distance units)
- `cutoff` = outer cutoff for interactions (distance units)
- `flagHI` (optional) = 0/1 to exclude/include 1/r hydrodynamic interactions
- `flagVF` (optional) = 0/1 to exclude/include volume fraction corrections in the long-range isotropic terms

19.159.2 Examples

(all assume radius = 1)

```
pair_style lubricate 1.5 1 1 2.01 2.5
pair_coeff 1 1 2.05 2.8
pair_coeff * *

pair_style lubricate 1.5 1 1 2.01 2.5
pair_coeff * *
variable mu equal ramp(1,2)
fix 1 all adapt 1 pair lubricate mu * * v_mu
```

19.159.3 Description

Styles lubricate and lubricate/poly compute hydrodynamic interactions between mono-disperse finite-size spherical particles in a pairwise fashion. The interactions have 2 components. The first is Ball-Melrose lubrication terms via the formulas in (Ball and Melrose)

```
W = -a_{sq}\|(v_1 - v_2)\cdot nn\|^2 - a_{sh}\|(\omega_1 + \omega_2)\cdot (I - nn) - 2\Omega_N|^2 -
    a_{pu}\|(\omega_1 - \omega_2)\cdot (I - nn)^2 - a_{tw}\|(\omega_1 - \omega_2)\cdot nn|^2 \quad r < r_c

\Omega_N = n \times (v_1 - v_2)/r
```
which represents the dissipation $W$ between two nearby particles due to their relative velocities in the presence of a background solvent with viscosity $\mu$. Note that this is dynamic viscosity which has units of mass/distance/time, not kinematic viscosity.

The $A_s q$ (squeeze) term is the strongest and is included if $flagHI$ is set to 1 (default). It scales as $1/gap$ where gap is the separation between the surfaces of the 2 particles. The $A_s h$ (shear) and $A_{pu}$ (pump) terms are only included if $flaglog$ is set to 1. They are the next strongest interactions, and the only other singular interaction, and scale as $\log(gap)$. Note that $flaglog = 1$ and $flagHI = 0$ is invalid, and will result in a warning message, after which $flagHI$ will be set to 1. The $A_t w$ (twist) term is currently not included. It is typically a very small contribution to the lubrication forces.

The $flagHI$ and $flagVF$ settings are optional. Neither should be used, or both must be defined.

$Cutinner$ sets the minimum center-to-center separation that will be used in calculations irrespective of the actual separation. $Cutoff$ is the maximum center-to-center separation at which an interaction is computed. Using a $cutoff$ less than 3 radii is recommended if $flaglog$ is set to 1.

The other component is due to the Fast Lubrication Dynamics (FLD) approximation, described in (Kumar), which can be represented by the following equation

$$F^H = -R_{FU}(U - U^\infty) + R_{FE}E^\infty$$

where $U$ represents the velocities and angular velocities of the particles, $U^\infty$ represents the velocity and the angular velocity of the undisturbed fluid, and $E^\infty$ represents the rate of strain tensor of the undisturbed fluid with viscosity $\mu$. Again, note that this is dynamic viscosity which has units of mass/distance/time, not kinematic viscosity. Volume fraction corrections to $R_{FU}$ are included as long as $flagVF$ is set to 1 (default).

**Note:** When using the FLD terms, these pair styles are designed to be used with explicit time integration and a correspondingly small timestep. Thus either $fix nve/sphere$ or $fix nve/asphere$ should be used for time integration. To perform implicit FLD, see the $pair_style lubricateU$ command.

Style $lubricate$ requires monodisperse spherical particles; style $lubricate/poly$ allows for polydisperse spherical particles.

The viscosity $\mu$ can be varied in a time-dependent manner over the course of a simulation, in which case the pair_style setting for $\mu$ will be overridden. See the $fix adapt$ command for details.

If the suspension is sheared via the $fix deform$ command then the pair style uses the shear rate to adjust the hydrodynamic interactions accordingly. Volume changes due to fix deform are accounted for when computing the volume fraction corrections to $R_{FU}$.

When computing the volume fraction corrections to $R_{FU}$, the presence of walls (whether moving or stationary) will affect the volume fraction available to colloidal particles. This is currently accounted for with the following types of walls: $wall/lj93$, $wall/lj126$, $wall/colloid$, and $wall/harmonic$. For these wall styles, the correct volume fraction will be used when walls do not coincide with the box boundary, as well as when walls move and thereby cause a change in the volume fraction. Other wall styles will still work, but they will result in the volume fraction being computed based on the box boundaries.

Since lubrication forces are dissipative, it is usually desirable to thermostat the system at a constant temperature. If Brownian motion (at a constant temperature) is desired, it can be set using the $pair_style brownian$ command. These pair styles and the brownian style should use consistent parameters for $\mu$, $flaglog$, $flagfld$, $cutinner$, $cutoff$, $flagHI$ and $flagVF$.

The following coefficients must be defined for each pair of atoms types via the $pair_coeff$ command as in the examples above, or in the data file or restart files read by the $read_data$ or $read_restart$ commands, or by mixing as described below:

- $cutinner$ (distance units)

### 19.159. $pair_style lubricate/poly command$
• cutoff (distance units)

The two coefficients are optional. If neither is specified, the two cutoffs specified in the pair_style command are used. Otherwise both must be specified.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

19.159.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the two cutoff distances for this pair style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the pair_modify shift option for the energy of the pair interaction.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

19.159.5 Restrictions

These styles are part of the COLLOID package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

Only spherical monodisperse particles are allowed for pair_style lubricate.

Only spherical particles are allowed for pair_style lubricate/poly.

These pair styles will not restart exactly when using the read_restart command, though they should provide statistically similar results. This is because the forces they compute depend on atom velocities. See the read_restart command for more details.
19.159.6 Related commands

pair_coeff, pair_style lubricateU

19.160 pair_style lubricateU command

19.161 pair_style lubricateU/poly command

19.161.1 Syntax

```
pair_style style mu flaglog cutinner cutoff gdot flagHI flagVF
```

- style = lubricateU or lubricateU/poly
- mu = dynamic viscosity (dynamic viscosity units)
- flaglog = 0/1 to exclude/include log terms in the lubrication approximation
- cutinner = inner cut off distance (distance units)
- cutoff = outer cutoff for interactions (distance units)
- gdot = shear rate (1/time units)
- flagHI (optional) = 0/1 to exclude/include 1/r hydrodynamic interactions
- flagVF (optional) = 0/1 to exclude/include volume fraction corrections in the long-range isotropic terms

19.161.2 Examples

(all assume radius = 1)

```
pair_style lubricateU 1.5 1 2.01 2.5 0.01 1 1
pair_coeff 1 1 2.05 2.8
pair_coeff * *
```
19.161.3 Description

Styles *lubricateU* and *lubricateU/poly* compute velocities and angular velocities for finite-size spherical particles such that the hydrodynamic interaction balances the force and torque due to all other types of interactions.

The interactions have 2 components. The first is Ball-Melrose lubrication terms via the formulas in *(Ball and Melrose)*

\[
W = -a_{sq} |v_1 - v_2| \cdot |nn|^2 - a_{sh} |(\omega_1 + \omega_2) \cdot (I - nn)| - 2\Omega_N^2 - a_{pu} |(\omega_1 - \omega_2) \cdot (I - nn)|^2 \quad r < r_c
\]

where \(r_c\) is the cutoff radius.

\[
\Omega_N = n \times (v_1 - v_2)/r
\]

which represents the dissipation \(W\) between two nearby particles due to their relative velocities in the presence of a background solvent with viscosity \(\mu\). Note that this is dynamic viscosity which has units of mass/distance/time, not kinematic viscosity.

The \(A_{sq}\) (squeeze) term is the strongest and is included as long as \(flagHI\) is set to 1 (default). It scales as \(1/gap\) where gap is the separation between the surfaces of the 2 particles. The \(A_{sh}\) (shear) and \(A_{pu}\) (pump) terms are only included if \(flaglog\) is set to 1. They are the next strongest interactions, and the only other singular interaction, and scale as \(\log(gap)\). Note that \(flaglog = 1\) and \(flagHI = 0\) is invalid, and will result in a warning message, after which \(flagHI\) will be set to 1. The \(A_{tw}\) (twist) term is currently not included. It is typically a very small contribution to the lubrication forces.

The \(flagHI\) and \(flagVF\) settings are optional. Neither should be used, or both must be defined.

*Cutinner* sets the minimum center-to-center separation that will be used in calculations irrespective of the actual separation. *Cutoff* is the maximum center-to-center separation at which an interaction is computed. Using a *cutoff* less than 3 radii is recommended if *flaglog* is set to 1.

The other component is due to the Fast Lubrication Dynamics (FLD) approximation, described in *(Kumar)*. The equation being solved to balance the forces and torques is

\[
-R_{FU}(U - U^\infty) = -R_FE^\infty - F_{rest}
\]

where \(U\) represents the velocities and angular velocities of the particles, \(U^\infty\) represents the velocities and the angular velocities of the undisturbed fluid, and \(E^\infty\) represents the rate of strain tensor of the undisturbed fluid flow with viscosity \(\mu\). Again, note that this is dynamic viscosity which has units of mass/distance/time, not kinematic viscosity. Volume fraction corrections to \(R_{FU}\) are included if \(flagVF\) is set to 1 (default).

\(F_{rest}\) represents the forces and torques due to all other types of interactions, e.g. Brownian, electrostatic etc. Note that this algorithm neglects the inertial terms, thereby removing the restriction of resolving the small interal time scale, which may not be of interest for colloidal particles. This pair style solves for the velocity such that the hydrodynamic force balances all other types of forces, thereby resulting in a net zero force (zero inertia limit). When defining this pair style, it must be defined last so that when this style is invoked all other types of forces have already been computed. For the same reason, it won’t work if additional non-pair styles are defined (such as bond or Kspace forces) as they are calculated in LAMMPS after the pairwise interactions have been computed.

**Note:** When using these styles, the these pair styles are designed to be used with implicit time integration and a correspondingly larger timestep. Thus either *fix nve/noforce* should be used for spherical particles defined via *atom_style sphere* or *fix nve/asphere/noforce* should be used for spherical particles defined via *atom_style ellipsoid*. This is because the velocity and angular momentum of each particle is set by the pair style, and should not be reset by the time integration fix.

Style *lubricateU* requires monodisperse spherical particles; style *lubricateU/poly* allows for polydisperse spherical particles.
If the suspension is sheared via the `fix deform` command then the pair style uses the shear rate to adjust the hydrodynamic interactions accordingly. Volume changes due to `fix deform` are accounted for when computing the volume fraction corrections to R_FU.

When computing the volume fraction corrections to R_FU, the presence of walls (whether moving or stationary) will affect the volume fraction available to colloidal particles. This is currently accounted for with the following types of walls: `wall/lj93`, `wall/lj126`, `wall/colloid`, and `wall/harmonic`. For these wall styles, the correct volume fraction will be used when walls do not coincide with the box boundary, as well as when walls move and thereby cause a change in the volume fraction. To use these wall styles with `pair_style lubricateU` or `lubricateU/poly`, the `fld yes` option must be specified in the fix wall command.

Since lubrication forces are dissipative, it is usually desirable to thermostat the system at a constant temperature. If Brownian motion (at a constant temperature) is desired, it can be set using the `pair_style brownian` command. These pair styles and the brownian style should use consistent parameters for `mu`, `flaglog`, `flagfld`, `cutinner`, `cutoff`, `flagHI` and `flagVF`.

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- `cutinner` (distance units)
- `cutoff` (distance units)

The two coefficients are optional. If neither is specified, the two cutoffs specified in the pair_style command are used. Otherwise both must be specified.

19.161.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the two cutoff distances for this pair style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the `pair_modify shift` option for the energy of the pair interaction.

The `pair_modify table` option is not relevant for this pair style.

This pair style does not support the `pair_modify tail` option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so `pair_style` and `pair_coeff` commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

19.161.5 Restrictions

These styles are part of the COLLOID package. They are only enabled if LAMMPS was built with that package. See the `Build package` page for more info.

Currently, these pair styles assume that all other types of forces/torques on the particles have been already been computed when it is invoked. This requires this style to be defined as the last of the pair styles, and that no fixes apply additional constraint forces. One exception is the `fix wall/colloid` commands, which has an “fld” option to apply their wall forces correctly.
Only spherical monodisperse particles are allowed for pair_style lubricateU.

Only spherical particles are allowed for pair_style lubricateU/poly.

For sheared suspensions, it is assumed that the shearing is done in the xy plane, with x being the velocity direction and y being the velocity-gradient direction. In this case, one must use `fix deform` with the same rate of shear (erate).

19.164.3 Description

The `lj/mdf`, `buck/mdf` and `lennard/mdf` compute the standard 12-6 Lennard-Jones and Buckingham potential with the addition of a taper function that ramps the energy and force smoothly to zero between an inner and outer cutoff.

\[ E_{\text{smooth}}(r) = E(r) \times f(r) \]

The tapering, \( f(r) \), is done by using the Mei, Davenport, Fernando function (Mei).

\[
f(r) = \begin{cases} 
1.0 & \text{for } r < r_m \\
(1 - x)^3 \times (1 + 3x + 6x^2) & \text{for } r_m < r < r_{\text{cut}} \\
0.0 & \text{for } r \geq r_{\text{cut}} 
\end{cases}
\]

where

\[ x = \frac{(r - r_m)}{(r_{\text{cut}} - r_m)} \]

Here \( r_m \) is the inner cutoff radius and \( r_{\text{cut}} \) is the outer cutoff radius.

For the `lj/mdf` pair_style, the potential energy, \( E(r) \), is the standard 12-6 Lennard-Jones written in the epsilon/sigma form:

\[ E(r) = 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^{6} \right] \]

Either the first two or all of the following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file read by the `read_data`. The two cutoffs default to the global values and \( \epsilon \) and \( \sigma \) can also be determined by mixing as described below:

- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)
- \( r_m \) (distance units)
- \( r_{\text{cut}} \) (distance units)

For the `buck/mdf` pair_style, the potential energy, \( E(r) \), is the standard Buckingham potential with three required coefficients. The two cutoffs can be omitted and default to the corresponding global values:

\[ E(r) = A e^{-r/\rho} - \frac{C}{r^6} \]
For the `lennard/mdf` pair style, the potential energy, $E(r)$, is the standard 12-6 Lennard-Jones written in the A/B form:

$$E(r) = \frac{A}{r^{12}} - \frac{B}{r^6}$$

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above, or in the data file read by the `read_data` commands, or by mixing as described below. The two cutoffs default to their global values and must be either both given or both left out:

- $A$ (energy-distance^12 units)
- $B$ (energy-distance^6 units)
- $r_m$ (distance units)
- $r_{cut}$ (distance units)

### 19.164.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the $\epsilon$ and $\sigma$ coefficients and cutoff distances for the lj/mdf pair style can be mixed. The default mix value is geometric. See the “pair_modify” command for details. The other two pair styles buck/mdf and lennard/mdf do not support mixing, so all I,J pairs of coefficients must be specified explicitly.

None of the lj/mdf, buck/mdf, or lennard/mdf pair styles supports the `pair_modify` shift option or long-range tail corrections to pressure and energy.

These styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

These styles can only be used via the `pair` keyword of the `run_style respa` command. They do not support the `inner`, `middle`, `outer` keywords.

### 19.164.5 Restrictions

These pair styles can only be used if LAMMPS was built with the EXTRA-PAIR package. See the `Build package` doc page for more info.

19.165.3 Description

Note: The behavior of the MEAM potential for alloy systems has changed as of November 2010; see description below of the mixture_ref_t parameter

Pair style meam computes non-bonded interactions for a variety of materials using the modified embedded-atom method (MEAM) (Baskes). Conceptually, it is an extension to the original EAM method which adds angular forces. It is thus suitable for modeling metals and alloys with fcc, bcc, hcp and diamond cubic structures, as well as materials with covalent interactions like silicon and carbon. This meam pair style is a translation of the original Fortran version to C++. It is functionally equivalent but more efficient and has additional features. The Fortran version of the meam pair style has been removed from LAMMPS after the 12 December 2018 release.

In the MEAM formulation, the total energy $E$ of a system of atoms is given by:

$$E = \sum_i \left\{ F_i(\bar{\rho}_i) + \frac{1}{2} \sum_{i \neq j} \phi_{ij}(r_{ij}) \right\}$$

where $F$ is the embedding energy which is a function of the atomic electron density $\rho$, and $\phi$ is a pair potential interaction. The pair interaction is summed over all neighbors $J$ of atom $I$ within the cutoff distance. As with EAM, the multi-body nature of the MEAM potential is a result of the embedding energy term. Details of the computation of the embedding and pair energies, as implemented in LAMMPS, are given in (Gullet) and references therein.

The various parameters in the MEAM formulas are listed in two files which are specified by the pair_coeff command. These are ASCII text files in a format consistent with other MD codes that implement MEAM potentials, such as the
serial DYNAMO code and Warp. Several MEAM potential files with parameters for different materials are included in the “potentials” directory of the LAMMPS distribution with a “.meam” suffix. All of these are parameterized in terms of LAMMPS metal units.

Note that unlike for other potentials, cutoffs for MEAM potentials are not set in the pair_style or pair_coeff command; they are specified in the MEAM potential files themselves.

Only a single pair_coeff command is used with the meam style which specifies two MEAM files and the element(s) to extract information for. The MEAM elements are mapped to LAMMPS atom types by specifying N additional arguments after the second filename in the pair_coeff command, where N is the number of LAMMPS atom types:

- MEAM library file
- Element1, Element2, …
- MEAM parameter file
- N element names = mapping of MEAM elements to atom types

See the pair_coeff page for alternate ways to specify the path for the potential files.

As an example, the potentials/library.meam file has generic MEAM settings for a variety of elements. The potentials/SiC.meam file has specific parameter settings for a Si and C alloy system. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following pair_coeff command:

```
pair_coeff * * library.meam Si C sic.meam Si Si Si C
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first filename is the element library file. The list of elements following it extracts lines from the library file and assigns numeric indices to these elements. The second filename is the alloy parameter file, which refers to elements using the numeric indices assigned before. The arguments after the parameter file map LAMMPS atom types to elements, i.e. LAMMPS atom types 1,2,3 to the MEAM Si element. The final C argument maps LAMMPS atom type 4 to the MEAM C element.

If the second filename is specified as NULL, no parameter file is read, which simply means the generic parameters in the library file are used. Use of the NULL specification for the parameter file is discouraged for systems with more than a single element type (e.g. alloys), since the parameter file is expected to set element interaction terms that are not captured by the information in the library file.

If a mapping value is specified as NULL, the mapping is not performed. This can be used when a meam potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Note: If the second filename is NULL, the element names between the two filenames can appear in any order, e.g. “Si C” or “C Si” in the example above. However, if the second filename is not NULL (as in the example above), it contains settings that are indexed by numbers for the elements that precede it. Thus you need to insure that you list the elements between the filenames in an order consistent with how the values in the second filename are indexed. See details below on the syntax for settings in the second file.

The MEAM library file provided with LAMMPS has the name potentials/library.meam. It is the “meamf” file used by other MD codes. Aside from blank and comment lines (starting with # which can appear anywhere), it is formatted as a series of entries, each of which has 19 parameters and can span multiple lines:

```
elt, lat, z, ielement, atwt, alpha, b0, b1, b2, b3, alat, esub, asub, t0, t1, t2, t3, rozero, ibar
```

The elt and lat parameters are text strings, such as elt = Si or Cu and lat = dia or fcc. Because the library file is used by Fortran MD codes, these strings may be enclosed in single quotes, but this is not required. The other numeric parameters match values in the formulas above. The value of the elt string is what is used in the pair_coeff command
to identify which settings from the library file you wish to read in. There can be multiple entries in the library file with the same elt value; LAMMPS reads the first matching entry it finds and ignores the rest.

Other parameters in the MEAM library file correspond to single-element potential parameters:

- **lat** = lattice structure of reference configuration
- **z** = number of nearest neighbors in the reference structure
- **ielement** = atomic number
- **atwt** = atomic weight
- **alat** = lattice constant of reference structure
- **esub** = energy per atom (eV) in the reference structure at equilibrium
- **asub** = "A" parameter for MEAM (see e.g. (Baskes))

The \( \alpha, b0, b1, b2, b3, t0, t1, t2, t3 \) parameters correspond to the standard MEAM parameters in the literature (Baskes) (the b parameters are the standard beta parameters). Note that only parameters normalized to \( t0 = 1.0 \) are supported. The \( \text{rozero} \) parameter is an element-dependent density scaling that weights the reference background density (see e.g. equation 4.5 in (Gullet)) and is typically 1.0 for single-element systems. The \( \text{ibar} \) parameter selects the form of the function \( G(\text{Gamma}) \) used to compute the electron density; options are

<table>
<thead>
<tr>
<th>( G(\text{Gamma}) )</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 =&gt; ( G = \sqrt{1+\text{Gamma}} )</td>
<td>( G ) based on ( \sqrt{\text{Gamma}} )</td>
</tr>
<tr>
<td>1 =&gt; ( G = \exp(\text{Gamma}/2) )</td>
<td>( G ) based on ( \exp(\text{Gamma}/2) )</td>
</tr>
<tr>
<td>2 =&gt; not implemented</td>
<td></td>
</tr>
<tr>
<td>3 =&gt; ( G = 2/(1+\exp(-\text{Gamma})) )</td>
<td>( G ) based on ( 2/(1+\exp(-\text{Gamma})) )</td>
</tr>
<tr>
<td>4 =&gt; ( G = \sqrt{1+\text{Gamma}} )</td>
<td>( G ) based on ( \sqrt{1+\text{Gamma}} )</td>
</tr>
<tr>
<td>-5 =&gt; ( G = \pm \sqrt{\text{abs}(1+\text{Gamma})} )</td>
<td>( G ) based on ( \pm \sqrt{\text{abs}(1+\text{Gamma})} )</td>
</tr>
</tbody>
</table>

If used, the MEAM parameter file contains settings that override or complement the library file settings. Examples of such parameter files are in the potentials directory with a ".meam" suffix. Their format is the same as is read by other Fortran MD codes. Aside from blank and comment lines (start with # which can appear anywhere), each line has one of the following forms. Each line can also have a trailing comment (starting with #) which is ignored.

- \texttt{keyword = value}
- \texttt{keyword(I) = value}
- \texttt{keyword(I,J) = value}
- \texttt{keyword(I,J,K) = value}

The indices I, J, K correspond to the elements selected from the MEAM library file numbered in the order of how those elements were selected starting from 1. Thus for the example given before

\texttt{pair_coeff} * * library.meam Si C sic.meam Si Si Si C

an index of 1 would refer to Si and an index of 2 to C.

The recognized keywords for the parameter file are as follows:

- **rc** = cutoff radius for cutoff function; default = 4.0
- **delr** = length of smoothing distance for cutoff function; default = 0.1
- **rho0(I)** = relative density for element I (overwrites value read from meamf file)
- **Ec(I,J)** = cohesive energy of reference structure for I-J mixture
- **delta(I,J)** = heat of formation for I-J alloy; if Ec_IJ is input as zero, then LAMMPS sets Ec_IJ = (Ec_II + Ec_JJ)/2 - delta_IJ
- **alpha(I,J)** = alpha parameter for pair potential between I and J (can be computed from bulk modulus of reference structure)
- **re(I,J)** = equilibrium distance between I and J in the reference structure
- **Cmax(I,J,K)** = Cmax screening parameter when I-J pair is screened

---

19.165. **pair_style meam command**
by $K$ ($I<=J$); default = 2.8

$C_{\text{min}}(I,J,K) \ = \ C_{\text{min}}$ screening parameter when $I$-$J$ pair is screened
by $K$ ($I<=J$); default = 2.0

$lattce(I,J) = $ lattice structure of $I$-$J$ reference structure:

- fcc = face centered cubic
- bcc = body centered cubic
- hcp = hexagonal close-packed
- dim = dimer
- dia = diamond (interlaced fcc for alloy)
- dia3 = diamond structure with primary 1NN and secondary 3NN interaction
- b1 = rock salt (NaCl structure)
- c11 = MoSi2 structure
- l12 = Cu3Au structure (lower case L, followed by 12)
- b2 = CsCl structure (interpenetrating simple cubic)
- ch4 = methane-like structure, only for binary system
- lin = linear structure (180 degree angle)
- zig = zigzag structure with a uniform angle
- tri = H2O-like structure that has an angle

$nn2(I,J) = $ turn on second-nearest neighbor MEAM formulation for $I$-$J$ pair (see for example (Lee)).

- 0 = second-nearest neighbor formulation off
- 1 = second-nearest neighbor formulation on

default = 0

$attrac(I,J) = $ additional cubic attraction term in Rose energy $I$-$J$ pair potential

default = 0

$repuls(I,J) = $ additional cubic repulsive term in Rose energy $I$-$J$ pair potential

default = 0

$zbl(I,J) = $ blend the MEAM $I$-$J$ pair potential with the ZBL potential for small atom separations (ZBL)

default = 1

$theta(I,J) = $ angle between three atoms in line, zigzag, and trimer reference structures...
in degrees

default = 180

$gsmooth\_factor = $ factor determining the length of the $G$-function smoothing region; only significant for ibar=0 or ibar=4.

- 99.0 = short smoothing region, sharp step
- 0.5 = long smoothing region, smooth step

default = 99.0

$augt1 = $ integer flag for whether to augment $t1$ parameter by $3/5*t3$ to account for old vs. new meam formulations;

- 0 = don't augment $t1$
- 1 = augment $t1$

default = 1

$ialloy = $ integer flag to use alternative averaging rule for $t$ parameters, for comparison with the DYNAMO MEAM code

- 0 = standard averaging (matches ialloy=0 in DYNAMO)
- 1 = alternative averaging (matches ialloy=1 in DYNAMO)
- 2 = no averaging of $t$ (use single-element values)

default = 0

$mixture\_ref\_t = $ integer flag to use mixture average of $t$ to compute the background reference density for alloys, instead of the single-element values (see description and warning elsewhere in this doc page)

- 0 = do not use mixture averaging for $t$ in the reference density
- 1 = use mixture averaging for $t$ in the reference density
default = 0

erose_form = integer value to select the form of the Rose energy function
  (see description below).
  default = 0

emb_lin_neg = integer value to select embedding function for negative densities
  0 = F(rho)=0
  1 = F(rho) = -asub*esub*rho (linear in rho, matches DYNAMO)
  default = 0

bkgd_dyn = integer value to select background density formula
  0 = rho_bkgd = rho_ref_meam(a) (as in the reference structure)
  1 = rho_bkgd = rho0_meam(a)*Z_meam(a) (matches DYNAMO)
  default = 0

 Rc, delr, re are in distance units (Angstroms in the case of metal units). Ec and delta are in energy units (eV in the case of metal units).

Each keyword represents a quantity which is either a scalar, vector, 2d array, or 3d array and must be specified with the correct corresponding array syntax. The indices I,J,K each run from 1 to N where N is the number of MEAM elements being used.

Thus these lines

\[
\begin{align*}
\rho_0(2) &= 2.25 \\
\alpha(1,2) &= 4.37
\end{align*}
\]

set rho0 for the second element to the value 2.25 and set alpha for the alloy interaction between elements 1 and 2 to 4.37.

The augt1 parameter is related to modifications in the MEAM formulation of the partial electron density function. In recent literature, an extra term is included in the expression for the third-order density in order to make the densities orthogonal (see for example (Wang), equation 3d); this term is included in the MEAM implementation in lammps. However, in earlier published work this term was not included when deriving parameters, including most of those provided in the library.meam file included with lammps, and to account for this difference the parameter t1 must be augmented by 3/5**t3*. If augt1 = 1, the default, this augmentation is done automatically. When parameter values are fit using the modified density function, as in more recent literature, augt1 should be set to 0.

The mixture_ref_t parameter is available to match results with those of previous versions of lammps (before January 2011). Newer versions of lammps, by default, use the single-element values of the t parameters to compute the background reference density. This is the proper way to compute these parameters. Earlier versions of lammps used an alloy mixture averaged value of t to compute the background reference density. Setting mixture_ref_t = 1 gives the old behavior. WARNING: using mixture_ref_t = 1 will give results that are demonstrably incorrect for second-neighbor MEAM, and non-standard for first-neighbor MEAM; this option is included only for matching with previous versions of lammps and should be avoided if possible.

The parameters attrac and repuls, along with the integer selection parameter erose_form, can be used to modify the Rose energy function used to compute the pair potential. This function gives the energy of the reference state as a function of interatomic spacing. The form of this function is:

\[
\text{astar} = \alpha (*) (r/re - 1.d0)
\]

if erose_form = 0: erose = -Ec*(1+astar+a3*(astar**3)/(r/re))*exp(-astar)
if erose_form = 1: erose = -Ec*(1+astar+(-attrac+repuls/r)*(astar**3))*exp(-astar)
if erose_form = 2: erose = -Ec*(1 +astar + a3*(astar**3))*exp(-astar)

a3 = repuls, astar < 0
a3 = attrac, astar >= 0

Most published MEAM parameter sets use the default values attrac = repulse = 0. Setting repuls = attrac = delta corresponds to the form used in several recent published MEAM parameter sets, such as (Valone)
Note: The default form of the *erose* expression in LAMMPS was corrected in March 2009. The current version is correct, but may show different behavior compared with earlier versions of lammps with the attrac and/or repuls parameters are non-zero. To obtain the previous default form, use *erose_form = 1* (this form does not seem to appear in the literature). An alternative form (see e.g. (Lee2)) is available using *erose_form = 2*.

19.165.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, where types I and J correspond to two different element types, mixing is performed by LAMMPS with user-specifiable parameters as described above.

This pair style does not support the *pair_modify shift, table, and tail* options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the *pair_style and pair_coeff* commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run_style respa* command. It does not support the *inner, middle, outer* keywords.

19.165.5 Restrictions

The *meam* style is provided in the MEAM package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

The maximum number of elements, that can be read from the MEAM library file, is determined at compile time. The default is 5. If you need support for more elements, you have to change the define for the constant ‘maxelt’ at the beginning of the file src/MEAM/meam.h and update/recompile LAMMPS. There is no limit on the number of atoms types.

19.165.6 Related commands

*pair_coeff*, *pair_style eam*, *pair_style meam/spline*

19.165.7 Default

none

19.166 pair_style meam/spline command

Accelerator Variants: meam/spline/omp

19.166.1 Syntax

```
pair_style meam/spline
```

19.166.2 Examples

```
pair_style meam/spline
pair_coeff * * Ti.meam.spline Ti
pair_coeff * * Ti.meam.spline Ti O
```

19.166.3 Description

The **meam/spline** style computes pairwise interactions for metals using a variant of modified embedded-atom method (MEAM) potentials (Lenosky). For a single species (“old-style”) MEAM, the total energy \( E \) is given by

\[
E = \sum_{i < j} \phi(r_{ij}) + \sum_i U(n_i)
\]

\[
n_i = \sum_j \rho_i(r_{ij}) + \sum_{j < k, j, k \neq i} f(r_{ij})f(r_{ik})g[\cos(\theta_{jik})]
\]

where \( \rho_i \) is the density at atom \( i \), \( \theta_{jik} \) is the angle between atoms \( J, I, \) and \( K \) centered on atom \( I \). The five functions \( \phi, U, \rho, f, \) and \( g \) are represented by cubic splines.

The **meam/spline** style also supports a new style multicomponent modified embedded-atom method (MEAM) potential (Zhang), where the total energy \( E \) is given by

\[
E = \sum_{i < j} \phi_{ij}(r_{ij}) + \sum_i U_i(n_i)
\]

\[
n_i = \sum_j \rho_j(r_{ij}) + \sum_{j < k, j, k \neq i} f_j(r_{ij})f_k(r_{ik})g_{jk}[\cos(\theta_{jik})]
\]

where the five functions \( \phi, U, \rho, f, \) and \( g \) depend on the chemistry of the atoms in the interaction. In particular, if there are \( N \) different chemistries, there are \( N \) different \( U, \rho, \) and \( f \) functions, while there are \( N(N+1)/2 \) different \( \phi \) and \( g \) functions. The new style multicomponent MEAM potential files are indicated by the second line in the file starts with “meam/spline” followed by the number of elements and the name of each element.

The cutoffs and the coefficients for these spline functions are listed in a parameter file which is specified by the **pair_coeff** command. Parameter files for different elements are included in the “potentials” directory of the LAMMPS distribution and have a “.meam.spline” file suffix. All of these files are parameterized in terms of LAMMPS metal units.

Note that unlike for other potentials, cutoffs for spline-based MEAM potentials are not set in the pair_style or pair_coeff command; they are specified in the potential files themselves.

Unlike the EAM pair style, which retrieves the atomic mass from the potential file, the spline-based MEAM potentials do not include mass information; thus you need to use the **mass** command to specify it.
Only a single pair_coeff command is used with the meam/spline style which specifies a potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of spline-based MEAM elements to atom types

See the pair_coeff page for alternate ways to specify the path for the potential file.

As an example, imagine the Ti.meam.spline file has values for Ti (old style). In that case your LAMMPS simulation may only have one atom type which has to be mapped to the Ti element as follows:

```plaintext
pair_coeff * * Ti.meam.spline Ti
```

The first 2 arguments must be ** and there may be only one element following or NULL. Systems where there would be multiple atom types assigned to the same element are not supported by this pair style due to limitations in its implementation. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a meam/spline potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

An example with a two component spline (new style) is TiO.meam.spline, where the command

```plaintext
pair_coeff * * TiO.meam.spline Ti O
```

will map the first atom type to Ti and the second atom type to O. Note in this case that the species names need to match exactly with the names of the elements in the TiO.meam.spline file; otherwise an error will be raised. This behavior is different than the old style MEAM files.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

19.166.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair_modify shift, table, and tail options.

The meam/spline pair style does not write its information to binary restart files, since it is stored in an external potential parameter file. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

The meam/spline pair style can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.
19.166.5 Restrictions

This pair style requires the newton setting to be “on” for pair interactions.
This pair style does not support mapping multiple atom types to the same element.
This pair style is only enabled if LAMMPS was built with the MANYBODY package. See the Build package page for more info.

19.167.2 Examples

```
pair_style meam/sw/spline
pair_coeff * * * Ti.meam.sw.spline Ti
pair_coeff * * * Ti.meam.sw.spline Ti Ti Ti
```

19.167.3 Description

The meam/sw/spline style computes pairwise interactions for metals using a variant of modified embedded-atom method (MEAM) potentials (Lenosky) with an additional Stillinger-Weber (SW) term (Stillinger) in the energy. This form of the potential was first proposed by Nicklas, Fellinger, and Park (Nicklas). We refer to it as MEAM+SW. The total energy \( E \) is given by

\[
E = E_{MEAM} + E_{SW}
\]

\[
E_{MEAM} = \sum_{IJ} \phi(r_{IJ}) + \sum_{I} U(\rho_{I})
\]

\[
E_{SW} = \sum_{I} \sum_{JK} F(r_{IJ}) F(r_{IK}) G(\cos(\theta_{JIK}))
\]

\[
\rho_{I} = \sum_{J} \rho(r_{IJ}) + \sum_{JK} f(r_{IJ}) f(r_{IK}) g(\cos(\theta_{JIK}))
\]
where $\rho_I$ is the density at atom I, $\theta_{JKI}$ is the angle between atoms J, I, and K centered on atom I. The seven functions $\phi, F, G, U, \rho, f, g$ are represented by cubic splines.

The cutoffs and the coefficients for these spline functions are listed in a parameter file which is specified by the `pair_coeff` command. Parameter files for different elements are included in the “potentials” directory of the LAMMPS distribution and have a “.meam.sw.spline” file suffix. All of these files are parameterized in terms of LAMMPS metal units.

Note that unlike for other potentials, cutoffs for spline-based MEAM+SW potentials are not set in the pair_style or pair_coeff command; they are specified in the potential files themselves.

Unlike the EAM pair style, which retrieves the atomic mass from the potential file, the spline-based MEAM+SW potentials do not include mass information; thus you need to use the `mass` command to specify it.

Only a single `pair_coeff` command is used with the meam/sw/spline style which specifies a potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the `pair_coeff` command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of spline-based MEAM+SW elements to atom types

See the `pair_coeff` page for alternate ways to specify the path for the potential file.

As an example, imagine the Ti.meam.sw.spline file has values for Ti. If your LAMMPS simulation has 3 atoms types and they are all to be treated with this potential, you would use the following `pair_coeff` command:

```
pair_coeff * * Ti.meam.sw.spline Ti Ti Ti
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The three Ti arguments map LAMMPS atom types 1,2,3 to the Ti element in the potential file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a `meam/sw/spline` potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

**Note:** The `meam/sw/spline` style currently supports only single-element MEAM+SW potentials. It may be extended for alloy systems in the future.

Example input scripts that use this pair style are provided in the examples/PACKAGES/meam_sw_spline directory.

### 19.167.4 Mixing, shift, table, tail correction, restart, rRESPA info

The pair style does not support multiple element types or mixing. It has been designed for pure elements only.

This pair style does not support the `pair_modify` shift, table, and tail options.

The `meam/sw/spline` pair style does not write its information to binary restart files, since it is stored in an external potential parameter file. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

The `meam/sw/spline` pair style can only be used via the `pair` keyword of the `run_style respa` command. They do not support the `inner`, `middle`, `outer` keywords.
19.167.5 Restrictions

This pair style requires the `newton` setting to be “on” for pair interactions.

This pair style is only enabled if LAMMPS was built with the MANYBODY package. See the `Build package` page for more info.

19.167.6 Related commands

(Nicklas) The spline-based MEAM+SW format was first devised and used to develop potentials for bcc transition metals by Jeremy Nicklas, Michael Fellinger, and Hyoungki Park at The Ohio State University.

19.168 pair_style mesocnt command

19.168.1 Syntax

```
pair_style mesocnt
```

19.168.2 Examples

```
pair_style mesocnt
pair_coeff * * 10_10.cnt
```

19.168.3 Description

Style `mesocnt` implements a mesoscopic potential for the interaction of carbon nanotubes (CNTs). In this potential, CNTs are modelled as chains of cylindrical segments in which each infinitesimal surface element interacts with all other CNT surface elements with the Lennard-Jones (LJ) term adopted from the `airebo` style. The interaction energy is then computed by integrating over the surfaces of all interacting CNTs.

The potential is based on interactions between one cylindrical segment and infinitely or semi-infinitely long CNTs as described in (Volkov1). Chains of segments are converted to these (semi-)infinite CNTs bases on an approximate chain approach outlined in (Volkov2). This allows to simplify the computation of the interactions significantly and reduces the computational times to the same order of magnitude as for regular bead spring models where beads interact with the standard `pair_lj/cut` potential.
In LAMMPS, cylindrical segments are represented by bonds. Each segment is defined by its two end points ("nodes") which correspond to atoms in LAMMPS. For the exact functional form of the potential and implementation details, the reader is referred to the original papers (Volkov1) and (Volkov2).

The potential requires tabulated data provided in a single ASCII text file specified in the pair_coeff command. The first line of the file provides a time stamp and general information. The second line lists four integers giving the number of data points provided in the subsequent four data tables. The third line lists four floating point numbers: the CNT radius $R$, the LJ parameter sigma and two numerical parameters $\delta_1$ and $\delta_2$. These four parameters are given in Angstroms. This is followed by four data tables each separated by a single empty line. The first two tables have two columns and list the parameters $u_{\text{InfParallel}}$ and $\Gamma$ respectively. The last two tables have three columns giving data on a quadratic array and list the parameters $\Phi$ and $u_{\text{SemiParallel}}$ respectively. $u_{\text{InfParallel}}$ and $u_{\text{SemiParallel}}$ are given in eV/Angstrom, $\Phi$ is given in eV and $\Gamma$ is unitless.

Potential files for CNTs can be readily generated using the freely available code provided on

https://github.com/phankl/cntpot

Using the same approach, it should also be possible to generate potential files for other 1D systems such as boron nitride nanotubes.

**Note:** Because of their size, *mesocnt* style potential files are not bundled with LAMMPS. When compiling LAMMPS from source code, the file C_10_10.mesocnt should be downloaded transparently from https://download.lammps.org/potentials/C_10_10.mesocnt This file has as number of data points per table 1001. This is sufficient for NVT simulations. For proper energy conservation, we recommend using a potential file where the resolution for $\Phi$ is at least 2001 data points.

**Note:** The *mesocnt* style requires CNTs to be represented as a chain of atoms connected by bonds. Atoms need to be numbered consecutively within one chain. Atoms belonging to different CNTs need to be assigned different molecule IDs.

19.168.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing.

This pair style does not support the pair_modify shift, table, and tail options.

The *mesocnt* pair style do not write their information to binary restart files, since it is stored in tabulated potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.
19.168.5 Restrictions

This style is part of the MESONT package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This pair potential requires the *newton* setting to be “on” for pair interactions.

19.172.3 Description

The `edpd` style computes the pairwise interactions and heat fluxes for eDPD particles following the formulations in [Li2014_JCP] and [Li2015_CC]. The time evolution of an eDPD particle is governed by the conservation of momentum and energy given by

\[
\frac{d^2 \mathbf{r}_i}{dt^2} = \frac{d\mathbf{v}_i}{dt} = \mathbf{F}_i = \sum_{i \neq j} (\mathbf{F}^C_{ij} + \mathbf{F}^D_{ij} + \mathbf{F}^R_{ij})
\]

\[
C_v \frac{dT_i}{dt} = q_i = \sum_{i \neq j} (q^C_{ij} + q^V_{ij} + q^R_{ij}),
\]

where the three components of \( \mathbf{F}_i \) including the conservative force \( \mathbf{F}^C_{ij} \), dissipative force \( \mathbf{F}^D_{ij} \) and random force \( \mathbf{F}^R_{ij} \) are expressed as

\[
\mathbf{F}^C_{ij} = \alpha_{ij} \omega_C(r_{ij}) \mathbf{e}_{ij}
\]

\[
\mathbf{F}^D_{ij} = -\gamma \omega_D(r_{ij})(\mathbf{e}_{ij} \cdot \mathbf{v}_{ij}) \mathbf{e}_{ij}
\]

\[
\mathbf{F}^R_{ij} = \sigma \omega_R(r_{ij}) \xi_{ij} \Delta t^{-1/2} \mathbf{e}_{ij}
\]

\[
\omega_C(r) = 1 - r/r_c
\]

\[
\alpha_{ij} = A \cdot k_B(T_i + T_j)/2
\]

\[
\omega_D(r) = \omega^2_D(r) = (1 - r/r_c)^s
\]

\[
\sigma^2_{ij} = 4 \gamma k_B T_i T_j / (T_i + T_j)
\]

in which the exponent of the weighting function \( s \) can be defined as a temperature-dependent variable. The heat flux between particles accounting for the collisional heat flux \( q^C \), viscous heat flux \( q^V \), and random heat flux \( q^R \) are given
by

\[ q_i^C = \sum_{j \neq i} k_{ij} \omega_{CT}(r_{ij}) \left( \frac{1}{T_i} - \frac{1}{T_j} \right) \]

\[ q_i^V = \frac{1}{2C_v} \sum_{j \neq i} \left\{ \omega_D(r_{ij}) \left[ \gamma_{ij} (e_{ij} \cdot v_{ij})^2 - \frac{(\sigma_{ij})^2}{m} \right] - \sigma_{ij} \omega_R(r_{ij}) (e_{ij} \cdot v_{ij}) \xi_{ij} \right\} \]

\[ q_i^R = \sum_{j \neq i} \beta_{ij} \omega_{RT}(r_{ij}) dt^{-1/2} \xi_{ij} \]

\[ \omega_{CT}(r) = \omega_{RT}^2(r) = (1 - r/r_{ct})^{s_T} \]

\[ k_{ij} = C_v^2 \kappa (T_i + T_j)^2/4k_B \]

\[ \beta_{ij}^2 = 2k_Bk_{ij} \]

where the mesoscopic heat friction \( \kappa \) is given by

\[ \kappa = \frac{315k_B\nu}{2\pi C_v r_{ct}^5 P_T} \]

with \( \nu \) being the kinematic viscosity. For more details, see Eq.(15) in (Li2014_JCP).

The following coefficients must be defined in eDPD system for each pair of atom types via the pair_coeff command as in the examples above.

- A (force units)
- \( \gamma \) (force/velocity units)
- power_f (positive real)
- cutoff (distance units)
- kappa (thermal conductivity units)
- power_T (positive real)
- cutoff_T (distance units)
- optional keyword = power or kappa

The keyword power or kappa is optional. Both “power” and “kappa” require 4 parameters \( c_1, c_2, c_3, c_4 \) showing the temperature dependence of the exponent \( s(T) = \text{power}_f (1 + c_1(T - 1) + c_2(T - 1)^2 + c_3(T - 1)^3 + c_4(T - 1)^4) \) and of the mesoscopic heat friction \( s_T(T) = \kappa (1 + c_1(T - 1) + c_2(T - 1)^2 + c_3(T - 1)^3 + c_4(T - 1)^4) \). If the keyword power or kappa is not specified, the eDPD system will use constant power_f and \( \kappa \), which is independent to temperature changes.

The mdpd/rhosum style computes the local particle mass density \( \rho \) for mDPD particles by kernel function interpolation. The following coefficients must be defined for each pair of atom types via the pair_coeff command as in the examples above.

- cutoff (distance units)

The mdpd style computes the many-body interactions between mDPD particles following the formulations in (Li2013_POF). The dissipative and random forces are in the form same as the classical DPD, but the conservative force is local density dependent, which are given by

\[ F_{ij}^C = Aw_{c}(r_{ij})e_{ij} + B(\rho_i + \rho_j)w_d(r_{ij})e_{ij} \]

\[ F_{ij}^D = -\gamma\omega_D(r_{ij})(e_{ij} \cdot v_{ij})e_{ij} \]

\[ F_{ij}^R = \sigma\omega_R(r_{ij})\xi_{ij} \Delta t^{-1/2} e_{ij} \]
where the first term in $F_C$ with a negative coefficient $A < 0$ stands for an attractive force within an interaction range $r_c$, and the second term with $B > 0$ is the density-dependent repulsive force within an interaction range $r_d$.

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above.

- $A$ (force units)
- $B$ (force units)
- $\gamma$ (force/velocity units)
- cutoff_c (distance units)
- cutoff_d (distance units)

The `tdpd` style computes the pairwise interactions and chemical concentration fluxes for tDPD particles following the formulations in (Li2015_JCP). The time evolution of a tDPD particle is governed by the conservation of momentum and concentration given by

$$\frac{d^2 r_i}{dt^2} = \frac{d v_i}{dt} = F_i = \sum_{i \neq j} (F_{ij}^C + F_{ij}^D + F_{ij}^R)$$

$$\frac{d C_i}{dt} = Q_i = \sum_{i \neq j} (Q_{ij}^D + Q_{ij}^R) + Q_i^S$$

where the three components of $F_i$ including the conservative force $F_{ij}^C$, dissipative force $F_{ij}^D$ and random force $F_{ij}^R$ are expressed as

$$F_{ij}^C = A \omega_C (r_{ij}) e_{ij}$$
$$F_{ij}^D = -\gamma \omega_D (r_{ij}) (e_{ij} \cdot v_{ij}) e_{ij}$$
$$F_{ij}^R = \sigma \omega_R (r_{ij}) \xi_{ij} \Delta t^{-1/2} e_{ij}$$

$$\omega_C (r) = 1 - r/r_c$$
$$\omega_D (r) = \omega_C^2 (r) = (1 - r/r_c)^{power_f}$$

$$\sigma^2 = 2 \gamma k_B T$$

The concentration flux between two tDPD particles includes the Fickian flux $Q_{ij}^D$ and random flux $Q_{ij}^R$, which are given by

$$Q_{ij}^D = -\kappa_{ij} w_{DC} (r_{ij}) (C_i - C_j)$$
$$Q_{ij}^R = \epsilon_{ij} (C_i + C_j) w_{RC} (r_{ij}) \xi_{ij}$$

$$w_{DC} (r_{ij}) = w_{RC}^2 (r_{ij}) = (1 - r/r_{cc})^{power_{cc}}$$

$$\epsilon_{ij}^2 = m_s^2 \kappa_{ij} \rho$$

where the parameters kappa and epsilon determine the strength of the Fickian and random fluxes. $m_s$ is the mass of a single solute molecule. In general, $m_s$ is much smaller than the mass of a tDPD particle $m$. For more details, see (Li2015_JCP).

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above.

- $A$ (force units)
- $\gamma$ (force/velocity units)
- `power_f` (positive real)
• cutoff (distance units)
• cutoff_CC (distance units)
• $\kappa_i$ (diffusivity units)
• $\epsilon_i$ (diffusivity units)
• power_cc_i (positive real)

The last 3 values must be repeated Nspecies times, so that values for each of the Nspecies chemical species are specified, as indicated by the ‘I’ suffix. In the first pair_coeff example above for pair_style tdpd, Nspecies = 1. In the second example, Nspecies = 2, so 3 additional coeffs are specified (for species 2).

### 19.172.4 Example scripts

There are example scripts for using all these pair styles in examples/PACKAGES/mesodpd. The example for an eDPD simulation models heat conduction with source terms analog of periodic Poiseuille flow problem. The setup follows Fig.12 in (Li2014_JCP). The output of the short eDPD simulation (about 2 minutes on a single core) gives a temperature and density profiles as

![Temperature and Density Profiles](image)

The example for a mDPD simulation models the oscillations of a liquid droplet started from a liquid film. The mDPD parameters are adopted from (Li2013_POF). The short mDPD run (about 2 minutes on a single core) generates a particle trajectory which can be visualized as follows.

![Particle Trajectory](image)
The first image is the initial state of the simulation. If you click it a GIF movie should play in your browser. The second image is the final state of the simulation.

The example for a tDPD simulation computes the effective diffusion coefficient of a tDPD system using a method analogous to the periodic Poiseuille flow. The tDPD system is specified with two chemical species, and the setup follows Fig.1 in *Li2015_JCP*. The output of the short tDPD simulation (about one and a half minutes on a single core) gives the concentration profiles of the two chemical species as

19.172.5 Mixing, shift, table, tail correction, restart, rRESPA info

The styles *edpd*, *mdpd*, *mdpd/rhosum* and *tdpd* do not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

The styles *edpd*, *mdpd*, *mdpd/rhosum* and *tdpd* do not support the *pair_modify* shift, table, and tail options.

The styles *edpd*, *mdpd*, *mdpd/rhosum* and *tdpd* do not write information to binary restart files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.
19.172.6 Restrictions

The pair styles `edpd`, `mdpd`, `mdpd/rhosum` and `tdpd` are part of the DPD-MESO package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

19.172.7 Related commands

19.172.8 Default

`none`

19.173.1 Syntax

```
pair_style mesont/tpm cut table_path BendingMode TPMType
```

- `cut` = the cutoff distance
- `table_path` = the path to the potential table
- `BendingMode` = the parameter defining the type of the bending potential for nanotubes: 0 - harmonic bending (Srivastava), 1 - anharmonic potential of bending and bending-buckling (Zhigilei1)
- `TPMType` = the parameter determining the type of the inter-tube interaction term: 0 - segment-segment approach, 1 - segment-chain approach (Zhigilei2, Zhigilei3)

The segment-segment approach is approximately 5 times slower than segment-chain approximation. The parameter `BendingMode` also affects the calculation of the inter-tube interaction term when `TPMType = 1`. In this case, when `BendingMode = 1`, each continuous chain of segments is additionally replaced by a number of sub-chains divided by bending buckling kinks.
19.173.2 Examples

pair_style mesont/tpm 30.0 MESONT-TABTP_10_10.xrs 0 0

19.173.3 Description

The tubular potential model (TPM) force field is designed for mesoscopic simulations of interacting flexible nanotubes. The force field is based on the mesoscopic computational model suggested in Ref. \( \text{Srivastava} \). In this model, each nanotube is represented by a chain of mesoscopic elements in the form of stretchable cylindrical segments, where each segment consists of multiple atoms. Each nanotube is divided into segments by a sequence of nodes placed on the nanotube centerline. This sequence of nodes determines the spatial position of the cylindrical segments and defines the configuration of the entire tube.

The potential force field that controls the dynamic behavior of a system of interacting nanotubes is given by the following equation defining the potential energy of the system:

\[
U = U_{str} + U_{bnd} + U_{vdW}
\]

where \( U_{str} \) is the harmonic potential describing the stretching of nanotube \( \text{Srivastava} \), \( U_{bnd} \) is the potential for nanotube bending \( \text{Srivastava} \) and bending-buckling \( \text{Zhigilei1} \), and \( U_{vdW} \) is the potential describing van-der Waals interaction between nanotubes \( \text{Zhigilei2, Zhigilei3} \). The stretching energy, \( U_{str} \), is given by the sum of stretching energies of individual nanotube segments. The bending energy, \( U_{bnd} \), is given by the sum of bending energies in all internal nanotube nodes. The tube-tube interaction energy, \( U_{vdW} \), is calculated based on the tubular potential method suggested in Ref. \( \text{Zhigilei2} \). The tubular potential method is briefly described below.

The interaction between two straight nanotubes of arbitrary length and orientation is described by the approximate tubular potential developed in \( \text{Zhigilei3} \). This potential approximates the results of direct integration of carbon-carbon interatomic potential over the surfaces of the interacting nanotubes, with the force sources homogeneously distributed over the nanotube surfaces. The input data for calculation of tubular potentials are partially tabulated. For single-walled CNTs of arbitrary chirality, the tabulated potential data can be generated in the form of ASCII files TPMSSTP.xrs and TPMA.xrs by the stand-alone code TMDPotGen included in the tool directory of LAMMPS release. The potential provided with LAMMPS release, MESONT-TABTP_10_10.xrs, is tabulated for (10,10) nanotubes.

Calculations of the interaction between curved or bent nanotubes are performed on either segment-segment or segment-chain basis. In the first case, activated when parameter TPMType is equal to 0, the tubular potential is calculated for each pair of interacting mesoscopic segments. In this case, however, small potential barriers for inter-tube sliding are introduced. While relatively small, these barriers are still larger than the ones that originate from the atomic-scale corrugation in atomistic modeling of inter-tube interaction. The latter are too weak to prevent room-temperature rearrangements of defect-free CNT, while the artificial mesoscopic barriers due to the segment-segment interaction can impede sliding of nanotubes with respect to each other and affect the kinetics of structural rearrangements in a system of nanotubes at moderate mesoscopic temperatures. In the second case, activated when parameter TPMType is equal to 1, the inter-tube interaction term is calculated based on the segment-chain approach. In this case, for each NT segment, the list of its neighboring segments is divided into short continuous chains of segments belonging to individual nanotubes. For each pair of a segment and a chain, the curved chain is approximated by a straight equivalent nanotube based on the weighted approach suggested in Ref. \( \text{Zhigilei2} \). Finally, the interaction between the segment and straight equivalent chain is calculated based on the tubular potential. In this case, and in the absence of bending buckling (i.e., when parameter BendingMode is equal to 0), the tubular potential method ensures the absence of corrugation of the effective inter-tube interaction potential for curved nanotubes and eliminates any barriers for the inter-tube sliding. As a result, the tubular potential method can describe the spontaneous self-assembly of nanotubes into continuous networks of bundles \( \text{Zhigilei1, Zhigilei3} \).

The TMD force field has been used for generation of nanotube films, fibers, and vertically aligned forests of nanotubes. Mesoscopic dynamic simulations were used to prepare realistic structures of continuous networks of nanotube bundles.
and to study their structural and mechanical properties \((\text{Zhigilei1, Zhigilei3, Zhigilei4, Zhigilei5, Zhigilei6})\). With additional models for heat transfer, this force filed was also used to study the thermal transport properties of carbon nanotube films \((\text{Zhigilei7, Zhigilei8, Zhigilei8})\). The methods for modeling of the mechanical energy dissipation into heat (energy exchange between the dynamic degrees of freedom of the mesoscopic model and the energy of atomic vibrations that are not explicitly represented in the model) \((\text{Zhigilei10})\) and mesoscopic description of covalent cross-links between nanotubes \((\text{Banna})\) have also been developed but are not included in this first release of the LAMMPS implementation of the force field. Further details can be found in references provided below.

The MESONT package also provides TMDGen code designed to generate initial samples composed of straight and dispersed nanotubes of given chirality and length at a given material density, which is available in tools directory. In the generated samples, nanotubes are distributed with random positions and orientations. Both periodic and free boundary conditions are available along each axis of the system of coordinates. All parameters in the sample files generated with TMDGen are given in metal \textit{units}.

\subsection{19.173.4 Restrictions}

This pair style is a part of the MSEONT package, and it is only enabled if LAMMPS is built with that package. See the \textit{Build package} doc page for more information.

This pair potential requires use of \textit{mesont atomic style}.

This pair potential requires the \textit{newton} setting to be “on” for pair interactions.

The cutoff distance should be set to be at least \(\max\left\{2L_\text{max}, \sqrt{L_\text{max}^2/2 + (2R + T_\text{cut})^2}\right\}\), where \(L\) is the maximum segment length, \(R\) is the maximum tube radius, and \(T_\text{cut} = 10.2\,\text{\AA}\) is the maximum distance between the surfaces of interacting segments. Because of the use of extended chain concept at CNT ends, the recommended cutoff is \(3L\).

\textbf{Note:} Because of their size, \textit{mesont} style potential files are not bundled with LAMMPS. When compiling LAMMPS from source code, the file \texttt{TABTP\_10\_10.mesont} should be downloaded transparently from \url{https://download.lammps.org/potentials/TABTP\_10\_10.mesont}

The \texttt{TABTP\_10\_10.mesont} potential file is parameterized for metal \textit{units}. You can use the carbon nanotube mesoscopic force field with any LAMMPS units, but you would need to create your own potential files with coefficients listed in appropriate units, if your simulation does not use “metal” units.

The chirality parameters set during system generation must match the values specified during generation of the potential tables.

pair_coeff * * parmin potin Omega volpress yes nbody 1234 precision double
pair_coeff * * parmin potin Omega volpress yes nbody 12
```

19.174.3 Description

Within DFT quantum mechanics, generalized pseudopotential theory (GPT) (Moriarty1) provides a first-principles approach to multi-ion interatomic potentials in d-band transition metals, with a volume-dependent, real-space total-energy functional for the N-ion elemental bulk material in the form

\[
E_{\text{tot}}(\mathbf{R}_1 \ldots \mathbf{R}_N) = NE_{\text{vol}}(\Omega) + \frac{1}{2} \sum_{i,j}^\prime v_2(ij; \Omega) + \frac{1}{6} \sum_{i,j,k}^\prime v_3(ijk; \Omega) + \frac{1}{24} \sum_{i,j,k,l}^\prime v_4(ijkl; \Omega)
\]

where the prime on each summation sign indicates the exclusion of all self-interaction terms from the summation. The leading volume term \(E_{\text{vol}}\) as well as the two-ion central-force pair potential \(v_2\) and the three- and four-ion angular-force potentials, \(v_3\) and \(v_4\), depend explicitly on the atomic volume \(\Omega\), but are structure independent and transferable to all bulk ion configurations, either ordered or disordered, and with or without the presence of point and line defects. The simplified model GPT or MGPT (Moriarty2, Moriarty3), which retains the form of \(E_{\text{tot}}\) and permits more efficient large-scale atomistic simulations, derives from the GPT through a series of systematic approximations applied to \(E_{\text{vol}}\) and the potentials \(v_n\) that are valid for mid-period transition metals with nearly half-filled d bands.

Both analytic (Moriarty2) and matrix (Moriarty3) representations of MGPT have been developed. In the more general matrix representation, which can also be applied to f-band actinide metals and permits both canonical and non-canonical d/f bands, the multi-ion potentials are evaluated on the fly during a simulation through d- or f-state matrix multiplication, and the forces that move the ions are determined analytically. Fast matrix-MGPT algorithms have been developed independently by Glosli (Glosli, Moriarty3) and by Oppelstrup (Oppelstrup).

The mgpt pair style calculates forces, energies, and the total energy per atom, \(E_{\text{tot}}/N\), using the Oppelstrup matrix-MGPT algorithm. Input potential and control data are entered through the pair_coeff command. Each material treated requires input parmin and potin potential files, as shown in the above examples, as well as specification by the user of the initial atomic volume \(\Omega\) through pair_coeff. At the beginning of a time step in any simulation, the total volume...
of the simulation cell $V$ should always be equal to $\Omega N$, where $N$ is the number of metal ions present, taking into account the presence of any vacancies and/or interstitials in the case of a solid. In a constant-volume simulation, which is the normal mode of operation for the mgpt pair style, $\Omega$, $V$ and $N$ all remain constant throughout the simulation and thus are equal to their initial values. In a constant-stress simulation, the cell volume $V$ will change (slowly) as the simulation proceeds. After each time step, the atomic volume should be updated by the code as $\Omega = V/N$. In addition, the volume term $E_{\text{vol}}$ and the potentials $v_2$, $v_3$ and $v_4$ have to be removed at the end of the time step, and then respecified at the new value of $\Omega$. In all simulations, $\Omega$ must remain within the defined volume range for $E_{\text{vol}}$ and the potentials for the given material.

The default option volpress yes in the pair_coeff command includes all volume derivatives of $E_{\text{tot}}$ required to calculate the stress tensor and pressure correctly. The option volpress no disregards the pressure contribution resulting from the volume term $E_{\text{vol}}$, and can be used for testing and analysis purposes. The additional optional variable nbody controls the specific terms in $E_{\text{tot}}$ that are calculated. The default option and the normal option for mid-period transition and actinide metals is nbody 1234 for which all four terms in $E_{\text{tot}}$ are retained. The option nbody 12, for example, retains only the volume term and the two-ion pair potential term and can be used for GPT series-end transition metals that can be well described without $v_3$ and $v_4$. The nbody option can also be used to test or analyze the contribution of any of the four terms in $E_{\text{tot}}$ to a given calculated property.

The mgpt pair style makes extensive use of matrix algebra and includes optimized kernels for the BlueGene/Q architecture and the Intel/AMD (x86) architectures. When compiled with the appropriate compiler and compiler switches (-msse3 on x86, and using the IBM XL compiler on BG/Q), these optimized routines are used automatically. For BG/Q machines, building with the default Makefile for that architecture (e.g., “make bgq”) should enable the optimized algebra routines. For x-86 machines, there is a provided Makefile.mgptfast which enables the fast algebra routines, i.e. build LAMMPS with “make mgptfast”. The user will be informed in the output files of the matrix kernels in use. To further improve speed, on x86 the option precision single can be added to the pair_coeff command line, which improves speed (up to a factor of two) at the cost of doing matrix calculations with 7 digit precision instead of the default 16. For consistency the default option can be specified explicitly by the option precision double.

All remaining potential and control data are contained with the parmin and potin files, including cutoffs, atomic mass, and other basic MGPT variables. Specific MGPT potential data for the transition metals tantalum (Ta4 and Ta6.8x potentials), molybdenum (Mo5.2 potentials), and vanadium (V6.1 potentials) are contained in the LAMMPS potentials directory. The stored files are, respectively, Ta4.mgpt.parmin, Ta4.mgpt.potin, Ta6.8x.mgpt.parmin, Ta6.8x.mgpt.potin, Mo5.2.mgpt.parmin, Mo5.2.mgpt.potin, V6.1.mgpt.parmin, and V6.1.mgpt.potin. Useful corresponding informational “README” files on the Ta4, Ta6.8x, Mo5.2 and V6.1 potentials are also included in the potentials directory. These latter files indicate the volume mesh and range for each potential and give appropriate references for the potentials. It is expected that MGPT potentials for additional materials will be added over time.

Useful example MGPT scripts are given in the examples/PACKAGES/mgpt directory. These scripts show the necessary steps to perform constant-volume calculations and simulations. It is strongly recommended that the user work through and understand these examples before proceeding to more complex simulations.

Note: For good performance, LAMMPS should be built with the compiler flags “-O3 -msse3 -funroll-loops” when including this pair style. The src/MAKE/OPTIONS/Makefile.mgptfast is an example machine Makefile with these options included as part of a standard MPI build. Note that it as provided, it will build with whatever low-level compiler (g++, icc, etc) is the default for your MPI installation.
19.174.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the `pair_modify` mix, shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

19.174.5 Restrictions

This pair style is part of the MGPT package and is only enabled if LAMMPS is built with that package. See the `Build package` page for more info.

The MGPT potentials require the `newtion` setting to be “on” for pair style interactions.

The stored parmin and potin potential files provided with LAMMPS in the “potentials” directory are written in Rydberg atomic units, with energies in Rybergs and distances in Bohr radii. The `mgpt` pair style converts Rydbergs to Hartrees to make the potential files compatible with LAMMPS electron units.

The form of E_tot used in the `mgpt` pair style is only appropriate for elemental bulk solids and liquids. This includes solids with point and extended defects such as vacancies, interstitials, grain boundaries and dislocations. Alloys and free surfaces, however, require significant modifications, which are not included in the `mgpt` pair style. Likewise, the `hybrid` pair style is not allowed, where MGPT would be used for some atoms but not for others.

Electron-thermal effects are not included in the standard MGPT potentials provided in the “potentials” directory, where the potentials have been constructed at zero electron temperature. Physically, electron-thermal effects may be important in 3d (e.g., V) and 4d (e.g., Mo) transition metals at high temperatures near melt and above. It is expected that temperature-dependent MGPT potentials for such cases will be added over time.

19.174.6 Related commands

`pair_coeff`

19.174.7 Default

The options defaults for the `pair_coeff` command are `volpress yes`, `nbody 1234`, and precision `double`.

19.175 pair_style mie/cut command

Accelerator Variants: mie/cut/gpu

19.175.1 Syntax

pair_style mie/cut cutoff

- cutoff = global cutoff for mie/cut interactions (distance units)

19.175.2 Examples

```plaintext
pair_style mie/cut 10.0
pair_coeff 1 1 0.72 3.40 23.00 6.66
pair_coeff 2 2 0.30 3.55 12.65 6.00
pair_coeff 1 2 0.46 3.32 16.90 6.31
```

19.175.3 Description

The mie/cut style computes the Mie potential, given by

\[ E = C \epsilon \left( \frac{\sigma}{r} \right)^{\gamma_{rep}} - \left( \frac{\sigma}{r} \right)^{\gamma_{att}} \quad r < r_c \]

Rc is the cutoff and C is a function that depends on the repulsive and attractive exponents, given by:

\[ C = \left( \frac{\gamma_{rep}}{\gamma_{rep} - \gamma_{att}} \right) \left( \frac{\gamma_{rep}}{\gamma_{att}} \right)^{\gamma_{rep} - \gamma_{att}} \]

Note that for 12/6 exponents, C is equal to 4 and the formula is the same as the standard Lennard-Jones potential.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- epsilon (energy units)
- sigma (distance units)
- gammaR
- gammaA
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff specified in the pair_style command is used.
19.175.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I != J, the epsilon and sigma coefficients and cutoff distance for all of the mie/cut pair styles can be mixed. If not explicitly defined, both the repulsive and attractive gamma exponents for different atoms will be calculated following the same mixing rule defined for distances. The default mix value is geometric. See the “pair_modify” command for details.

This pair style supports the pair_modify shift option for the energy of the pair interaction.

This pair style supports the pair_modify tail option for adding a long-range tail correction to the energy and pressure of the pair interaction.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style supports the use of the inner, middle, and outer keywords of the run_style respa command, meaning the pairwise forces can be partitioned by distance at different levels of the rRESPA hierarchy. See the run_style command for details.

19.175.5 Restrictions

This pair style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

19.176 pair_style mliap command

19.176.1 Syntax

pair_style mliap ... keyword values ...

- two keyword/value pairs must be appended
- keyword = model or descriptor
model values = style filename
style = linear or quadratic or nn or mliappy
filename = name of file containing model definitions
descriptor values = style filename
style = sna or so3
filename = name of file containing descriptor definitions

19.176.2 Examples

```
pair_style mliap model linear InP.mliap.model descriptor sna InP.mliap.descriptor
pair_style mliap model quadratic W.mliap.model descriptor sna W.mliap.descriptor
pair_style mliap model nn Si.nn.mliap.model descriptor so3 Si.nn.mliap.descriptor
pair_coeff * * InP
```

19.176.3 Description

Pair style *mliap* provides a general interface to families of machine-learning interatomic potentials. It allows separate definitions of the interatomic potential functional form (*model*) and the geometric quantities that characterize the atomic positions (*descriptor*). By defining *model* and *descriptor* separately, it is possible to use many different models with a given descriptor, or many different descriptors with a given model. The pair style currently supports only *sna* and *so3* descriptor styles, but it is straightforward to add new descriptor styles.

The SNAP descriptor style *sna* is the same as that used by *pair_style snap*, including the linear, quadratic, and chem variants. The available models are *linear*, *quadratic*, *nn*, and *mliappy*. The *mliappy* style can be used to couple python models, e.g. PyTorch neural network energy models, and requires building LAMMPS with the PYTHON package (see below). In order to train a model, it is useful to know the gradient or derivative of energy, force, and stress w.r.t. model parameters. This information can be accessed using the related *compute mliap* command.

The descriptor style *so3* is a descriptor that is derived from the the smooth SO(3) power spectrum with the explicit inclusion of a radial basis (Bartok) and (Zagaceta). The available models are *linear* and *nn*.

The pair style *mliap* command must be followed by two keywords *model* and *descriptor* in either order. A single *pair_coeff* command is also required. The first 2 arguments must be * * so as to span all LAMMPS atom types. This is followed by a list of N arguments that specify the mapping of MLIAP element names to LAMMPS atom types, where N is the number of LAMMPS atom types.

The *model* keyword is followed by the model style. This is followed by a single argument specifying the model filename containing the parameters for a set of elements. The model filename usually ends in the *.mliap.model* extension. It may contain parameters for many elements. The only requirement is that it contain at least those element names appearing in the *pair_coeff* command.

The top of the model file can contain any number of blank and comment lines (start with #), but follows a strict format after that. The first non-blank non-comment line must contain two integers:

- nelems = Number of elements
- np parms = Number of parameters

When the *model* keyword is *linear* or *quadratic*, this is followed by one block for each of the nelem elements. Each block consists of nparms parameters, one per line. Note that this format is similar, but not identical to that used for the *pair_style snap* coefficient file. Specifically, the line containing the element weight and radius is omitted, since these are handled by the *descriptor*.

When the *model* keyword is *nn* (neural networks), the model file can contain blank and comment lines (start with #) anywhere. The second non-blank non-comment line must contain the string NET, followed by two integers:
• ndescriptors = Number of descriptors
• nlayers = Number of layers (including the hidden layers and the output layer)

and followed by a sequence of a string and an integer for each layer:
• Activation function (linear, sigmoid, tanh or relu)
• nnodes = Number of nodes

This is followed by one block for each of the nelem elements. Each block consists of scale0 minimum value, scale1 (maximum - minimum) value, in order to normalize the descriptors, followed by nparams parameters, including bias and weights of the model, starting with the first node of the first layer and so on, with a maximum of 30 values per line.

The detail of nn module implementation can be found at (Yanxon).

Notes on mliappy models

When the model keyword is mliappy, the filename should end in '.pt', '.pth' for pytorch models, or be a pickle file.

To load a model from memory (i.e. an existing python object), specify the filename as “LATER”, and then call lammps.mliap.load_model(model) from python before using the pair style. When using lammps via the library mode, you will need to call lammps.mliappy.activate_mliappy(lmp) on the active lammps object before the pair style is defined.

This call locates and loads the mliap-specific python module that is built into lammps.

The descriptor keyword is followed by a descriptor style, and additional arguments. Currently two descriptor styles are available: sna and so3.

• sna indicates the bispectrum component descriptors used by the Spectral Neighbor Analysis Potential (SNAP) potentials of pair_style snap. A single additional argument specifies the descriptor filename containing the parameters and setting used by the SNAP descriptor. The descriptor filename usually ends in the .mliap.descriptor extension.

• so3 indicated the power spectrum component descriptors. A single additional argument specifies the descriptor filename containing the parameters and setting.

The SNAP descriptor file closely follows the format of the pair_style snap parameter file. The file can contain blank and comment lines (start with #) anywhere. Each non-blank non-comment line must contain one keyword/value pair. The required keywords are rcutfac and twojmax. There are many optional keywords that are described on the pair_style snap doc page. In addition, the SNAP descriptor file must contain the nelems, elems, radelems, and welems keywords. The nelems keyword specifies the number of elements provided in the other three keywords. The elems keyword is followed by a list of nelems element names that must include the element names appearing in the pair_coeff command, but can contain other names too. Similarly, the radelems and welems keywords are followed by lists of nelems numbers giving the element radius and element weight of each element. Obviously, the order in which the elements are listed must be consistent for all three keywords.

The SO3 descriptor file is similar to the SNAP descriptor except that it contains a few more arguments (e.g., nmax and alpha). The preparation of SO3 descriptor and model files can be done with the Pyxtal_FF package.

See the pair_coeff page for alternate ways to specify the path for these model and descriptor files.

Note: To significantly reduce SO3 descriptor/force calculation time, some properties are pre-computed and reused during the calculation. These can consume a significant amount of RAM for simulations of larger systems since their size depends on the total number of neighbors per MPI process.
19.176.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I ≠ J, where types I and J correspond to two different element types, mixing is performed by LAMMPS with user-specifiable parameters as described above. You never need to specify a pair_coeff command with I ≠ J arguments for this style.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

19.176.5 Restrictions

This pair style is part of the ML-IAP package. It is only enabled if LAMMPS was built with that package. In addition, building LAMMPS with the ML-IAP package requires building LAMMPS with the ML-SNAP package. The mliappy model requires building LAMMPS with the PYTHON package. See the Build package page for more info.

19.176.6 Related commands

pair_style snap, compute mliap

19.176.7 Default

none

19.177 pair_style momb command

19.177.1 Syntax

pair_style momb cutoff s6 d

- cutoff = global cutoff (distance units)
- s6 = global scaling factor of the exchange-correlation functional used (unitless)
- d = damping scaling factor of Grimme’s method (unitless)
19.177.2 Examples

```plaintext
pair_style momb 12.0 0.75 20.0
pair_style hybrid/overlay eam/fs lj/charmm/coul/long 10.0 12.0 momb 12.0 0.75 20.0 morse
pair_coeff 1 2 momb 0.0 1.0 1.0 10.2847 2.361
```

19.177.3 Description

Style `momb` computes pairwise van der Waals (vdW) and short-range interactions using the Morse potential and (Grimme) method implemented in the Many-Body Metal-Organic (MOMB) force field described comprehensively in (Fichthorn) and (Zhou). Grimme’s method is widely used to correct for dispersion in density functional theory calculations.

\[
E = D_0 \left[ \exp^{-2\alpha(r-r_0)} - 2\exp^{-\alpha(r-r_0)} \right] - s_6 \frac{C_6}{r_0^6} f_{damp}(r, R_r)
\]

\[
f_{damp}(r, R_r) = \frac{1}{1 + \exp^{-d(r/R_r-1)}}
\]

For the `momb` pair style, the following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` as described below:

- \(D_0\) (energy units)
- \(\alpha\) (1/distance units)
- \(r_0\) (distance units)
- \(C_6\) (energy*distance^6 units)
- \(R_r\) (distance units, typically sum of atomic vdW radii)

19.177.4 Restrictions

This style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS is built with that package. See the Build package page on for more info.

19.177.5 Related commands

`pair_coeff, pair_style morse`

19.177.6 Default

none

(Fichthorn) Fichthorn, Balankura, Qi, CrystEngComm, 18(29), 5410-5417 (2016).
19.178 pair_style morse command

Accelerator Variants: morse/gpu, morse/omp, morse/opt, morse/kk

19.179 pair_style morse/smooth/linear command

Accelerator Variants: morse/smooth/linear/omp

19.179.1 Syntax

```
pair_style style args
```

- style = morse or morse/smooth/linear or morse/soft
- args = list of arguments for a particular style

```
morse args = cutoff
cutoff = global cutoff for Morse interactions (distance units)
morse/smooth/linear args = cutoff
cutoff = global cutoff for Morse interactions (distance units)
```

19.179.2 Examples

```
pair_style morse 2.5
pair_style morse/smooth/linear 2.5
pair_coeff * * 100.0 2.0 1.5
pair_coeff 1 1 100.0 2.0 1.5 3.0
```

19.179.3 Description

Style `morse` computes pairwise interactions with the formula

\[
E = D_0 \left[ e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)} \right] \quad r < r_c
\]

\(r_c\) is the cutoff.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \(D_0\) (energy units)
- \(\alpha\) (1/distance units)
- \(r_0\) (distance units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global morse cutoff is used.
The *morse/smooth/linear* variant is similar to the *lj/smooth/linear* variant in that it adds to the potential a shift and a linear term so that both, potential energy and force, go to zero at the cut-off:

\[
\phi(r) = D_0 \left[ e^{-2\alpha(r-r_0)} - 2e^{-\alpha(r-r_0)} \right] \quad r < r_c
\]

\[
E(r) = \phi(r) - \phi(R_c) - (r - R_c) \frac{d\phi}{dr} \bigg|_{r=R_c} \quad r < R_c
\]

The syntax of the pair_style and pair_coeff commands are the same for the *morse* and *morse/smooth/linear* styles.

A version of the *morse* style with a soft core, *morse/soft*, suitable for use in free energy calculations, is part of the FEP package and is documented with the *pair_style *soft* styles. The version with soft core is only available if LAMMPS was built with that package. See the Build package page for more info.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 19.179.4 Mixing, shift, table, tail correction, restart, rRESPA info

None of these pair styles support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

All of these pair styles support the pair_modify shift option for the energy of the pair interaction.

The pair_modify table options is not relevant for the Morse pair styles.

None of these pair styles support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

All of these pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.
19.179.5 Restrictions

The morse/smooth/linear pair style is only enabled if LAMMPS was built with the EXTRA-PAIR package. See the Build package page for more info.

19.179.6 Related commands

pair_coeff, pair_style */soft

19.179.7 Default

19.180 pair_style multi/lucy command

19.180.1 Syntax

```
pair_style multi/lucy style N keyword ...
```

- style = lookup or linear = method of interpolation
- N = use N values in lookup, linear tables

19.180.2 Examples

```
pair_style multi/lucy linear 1000
pair_coeff * * multibody.table ENTRY1 7.0
```

19.180.3 Description

Style multi/lucy computes a density-dependent force following from the many-body form described in (Moore) and (Warren) as

\[ F_{i}^{DD} (\rho_i, \rho_j, r_{ij}) = \frac{1}{2} \omega_{DD} (r_{ij}) \left[ A (\rho_i) + A (\rho_j) \right] e_{ij} \]

which consists of a density-dependent function, \(A(\rho)\), and a radial-dependent weight function, \(\omega_{DD}(r_{ij})\). The radial-dependent weight function, \(\omega_{DD}(r_{ij})\), is taken as the Lucy function:

\[ \omega_{DD} (r_{ij}) = \left( 1 + \frac{3 r_{ij}}{r_{cut}} \right) \left( 1 + \frac{r_{ij}}{r_{cut}} \right)^3 \]

The density-dependent energy for a given particle is given by:

\[ u_{i}^{DD} (\rho_i) = \frac{\pi r_{cut}^4}{84} \int_{\rho_0}^{\rho_i} A (\rho') d\rho' \]

See the supporting information of (Brennan) or the publication by (Moore) for more details on the functional form.
An interpolation table is used to evaluate the density-dependent energy ($\int A(\rho')d\rho'$) and force ($A(\rho')$). Note that the prefactor to the energy is computed after the interpolation, thus the $\int A(\rho')d\rho'$ will have units of energy / length$^4$.

The interpolation table is created as a pre-computation by fitting cubic splines to the file values and interpolating the density-dependent energy and force at each of $N$ densities. During a simulation, the tables are used to interpolate the density-dependent energy and force as needed for each pair of particles separated by a distance $R$. The interpolation is done in one of 2 styles: lookup and linear.

For the lookup style, the density is used to find the nearest table entry, which is the density-dependent energy and force.

For the linear style, the density is used to find the 2 surrounding table values from which the density-dependent energy and force are computed by linear interpolation.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above.

- filename
- keyword
- cutoff (distance units)

The filename specifies a file containing the tabulated density-dependent energy and force. The keyword specifies a section of the file. The cutoff is an optional coefficient. If not specified, the outer cutoff in the table itself (see below) will be used to build an interpolation table that extend to the largest tabulated distance. If specified, only file values up to the cutoff are used to create the interpolation table. The format of this file is described below.

The format of a tabulated file is a series of one or more sections, defined as follows (without the parenthesized comments):

`# Density-dependent function (one or more comment or blank lines)`

```
DD-FUNCTION (keyword is first text on line)
N 500 R 1.0 10.0 (N, R, RSQ parameters)
(blank)
1 1.0 25.5 102.34 (index, density, energy/r^4, force)
2 1.02 23.4 98.5
...
500 10.0 0.001 0.003
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the `pair_coeff` command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the $N$ specified in the `pair_style multi/lucy` command. Let $\text{Ntable} = N$ in the `pair_style` command, and $\text{Nfile} = \text{“N”}$ in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the $\text{Nfile}$ tabulated values as nodal points. It uses these to interpolate the density-dependent energy and force at $\text{Ntable}$ different points. The resulting tables of length $\text{Ntable}$ are then used as described above, when computing the density-dependent energy and force. This means that if you want the interpolation tables of length $\text{Ntable}$ to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set $\text{Ntable} = \text{Nfile}$, and use the “RSQ” parameter. This is because the internal table abscissa is always RSQ (separation distance squared), for efficient lookup.

All other parameters are optional. If “R” or “RSQ” does not appear, then the distances in each line of the table are used as-is to perform spline interpolation. In this case, the table values can be spaced in density uniformly or however you wish to position table values in regions of large gradients.
If used, the parameters “R” or “RSQ” are followed by 2 values $r_{lo}$ and $r_{hi}$. If specified, the density associated with each density-dependent energy and force value is computed from these 2 values (at high accuracy), rather than using the (low-accuracy) value listed in each line of the table. The density values in the table file are ignored in this case. For “R”, distances uniformly spaced between $r_{lo}$ and $r_{hi}$ are computed; for “RSQ”, squared distances uniformly spaced between $r_{lo}^2$ and $r_{hi}^2$ are computed.

**Note:** If you use “R” or “RSQ”, the tabulated distance values in the file are effectively ignored, and replaced by new values as described in the previous paragraph. If the density value in the table is not very close to the new value (i.e. round-off difference), then you will be assigning density-dependent energy and force values to a different density, which is probably not what you want. LAMMPS will warn if this is occurring.

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is r (in density units), the third value is the density-dependent function value (in energy units / length$^4$), and the fourth is the force (in force units). The density values must increase from one line to the next.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

### 19.180.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

The `pair_modify` shift, table, and tail options are not relevant for this pair style.

This pair style writes the settings for the “pair_style multi/lucy” command to binary restart files, so a pair_style command does not need to specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, `pair_coeff` commands do need to be specified in the restart input script.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

### 19.180.5 Restrictions

This command is part of the DPD-REACT package. It is only enabled if LAMMPS was built with that package. See the `Build package` page for more info.

### 19.180.6 Related commands

`pair_coeff`

pair_coeff * * multibody.table ENTRY1 h2o 1fluid 7.0
```

19.181.3 Description

Style `multi/lucy/rx` is used in reaction DPD simulations, where the coarse-grained (CG) particles are composed of \( m \) species whose reaction rate kinetics are determined from a set of \( n \) reaction rate equations through the `fix rx` command. The species of one CG particle can interact with a species in a neighboring CG particle through a site-site interaction potential model. Style `multi/lucy/rx` computes the site-site density-dependent force following from the many-body form described in (Moore) and (Warren) as

\[
F_{iDD}(\rho_i, \rho_j, r_{ij}) = \frac{1}{2} \omega_{DD}(r_{ij}) \left[ A(\rho_i) + A(\rho_j) \right] e_{ij}
\]

which consists of a density-dependent function, \( A(\rho) \), and a radial-dependent weight function, \( \omega_{DD}(r_{ij}) \). The radial-dependent weight function, \( \omega_{DD}(r_{ij}) \), is taken as the Lucy function:

\[
\omega_{DD}(r_{ij}) = \left( 1 + \frac{3r_{ij}}{r_{cut}} \right) \left( 1 + \frac{r_{ij}}{r_{cut}} \right)^3
\]
The density-dependent energy for a given particle is given by:

\[ u_{i}^{DD}(\rho_{i}) = \frac{\pi r_{cut}^{4}}{84} \int_{\rho_{0}}^{\rho_{i}} A(\rho') d\rho' \]

See the supporting information of (Brennan) or the publication by (Moore) for more details on the functional form.

An interpolation table is used to evaluate the density-dependent energy (\( \int A(\rho')d\rho' \)) and force (\( A(\rho') \)). Note that the prefactor to the energy is computed after the interpolation, thus the \( \int A(\rho')d\rho' \) will have units of energy / length^4.

The interpolation table is created as a pre-computation by fitting cubic splines to the file values and interpolating the density-dependent energy and force at each of \( N \) densities. During a simulation, the tables are used to interpolate the density-dependent energy and force as needed for each pair of particles separated by a distance \( R \). The interpolation is done in one of 2 styles: lookup and linear.

For the lookup style, the density is used to find the nearest table entry, which is the density-dependent energy and force.

For the linear style, the density is used to find the 2 surrounding table values from which the density-dependent energy and force are computed by linear interpolation.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above.

- filename
- keyword
- species1
- species2
- cutoff (distance units)

The filename specifies a file containing the tabulated density-dependent energy and force. The keyword specifies a section of the file. The cutoff is an optional coefficient. If not specified, the outer cutoff in the table itself (see below) will be used to build an interpolation table that extend to the largest tabulated distance. If specified, only file values up to the cutoff are used to create the interpolation table. The format of this file is described below.

The species tags define the site-site interaction potential between two species contained within two different particles. The species tags must either correspond to the species defined in the reaction kinetics files specified with the fix rx command or they must correspond to the tag “1fluid”, signifying interaction with a product species mixture determined through a one-fluid approximation. The interaction potential is weighted by the geometric average of either the mole fraction concentrations or the number of molecules associated with the interacting coarse-grained particles (see the fractional or molecular weighting pair style options). The coarse-grained potential is stored before and after the reaction kinetics solver is applied, where the difference is defined to be the internal chemical energy (uChem).

The format of a tabulated file is a series of one or more sections, defined as follows (without the parenthesized comments):

```
# Density-dependent function (one or more comment or blank lines)

DD-FUNCTION (keyword is first text on line)
N  500  R  1.0  10.0   (N, R, RSQ parameters)
    (blank)
    1  1.0  25.5  102.34 (index, density, energy/r^4, force)
    2  1.02  23.4  98.5
    ...
    500  10.0  0.001  0.003
```

19.181. pair_style multi/lucy/rx command

2147
A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the pair_coeff command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the $N$ specified in the pair_style multi/lucy/rx command. Let Ntable = $N$ in the pair_style command, and Nfile = “N” in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the Nfile tabulated values as nodal points. It uses these to interpolate the density-dependent energy and force at Ntable different points. The resulting tables of length Ntable are then used as described above, when computing the density-dependent energy and force. This means that if you want the interpolation tables of length Ntable to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set Ntable = Nfile, and use the “RSQ” parameter. This is because the internal table abscissa is always RSQ (separation distance squared), for efficient lookup.

All other parameters are optional. If “R” or “RSQ” does not appear, then the distances in each line of the table are used as-is to perform spline interpolation. In this case, the table values can be spaced in density uniformly or however you wish to position table values in regions of large gradients.

If used, the parameters “R” or “RSQ” are followed by 2 values $rlo$ and $rhi$. If specified, the density associated with each density-dependent energy and force value is computed from these 2 values (at high accuracy), rather than using the (low-accuracy) value listed in each line of the table. The density values in the table file are ignored in this case. For “R”, distances uniformly spaced between $rlo$ and $rhi$ are computed; for “RSQ”, squared distances uniformly spaced between $rlo*rlo$ and $rhi*rhi$ are computed.

Note: If you use “R” or “RSQ”, the tabulated distance values in the file are effectively ignored, and replaced by new values as described in the previous paragraph. If the density value in the table is not very close to the new value (i.e. round-off difference), then you will be assigning density-dependent energy and force values to a different density, which is probably not what you want. LAMMPS will warn if this is occurring.

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is r (in density units), the third value is the density-dependent function value (in energy units / length^4), and the fourth is the force (in force units). The density values must increase from one line to the next.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

### 19.181.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

The pair_modify shift, table, and tail options are not relevant for this pair style.

This pair style writes the settings for the “pair_style multi/lucy/rx” command to binary restart files, so a pair_style command does not need to specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, pair_coeff commands do need to be specified in the restart input script.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages.
The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

---

### 19.181.5 Restrictions

This command is part of the DPD-REACT package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

### 19.181.6 Related commands

- `pair_coeff`

### 19.181.7 Default

### 19.182 pair_style nb3b/harmonic command

#### 19.182.1 Syntax

```
pair_style nb3b/harmonic
```

#### 19.182.2 Examples

```
pair_style nb3b/harmonic
pair_coeff * * MgOH.nb3bharmonic Mg O H
```
19.182.3 Description

This pair style computes a non-bonded 3-body harmonic potential for the energy $E$ of a system of atoms as

$$E = K(\theta - \theta_0)^2$$

where $\theta_0$ is the equilibrium value of the angle and $K$ is a prefactor. Note that the usual 1/2 factor is included in $K$. The form of the potential is identical to that used in angle_style harmonic, but in this case, the atoms do not need to be explicitly bonded.

Only a single pair_coeff command is used with this style which specifies a potential file with parameters for specified elements. These are mapped to LAMMPS atom types by specifying $N$ additional arguments after the filename in the pair_coeff command, where $N$ is the number of LAMMPS atom types:

- filename
- $N$ element names = mapping of elements to atom types

See the pair_coeff page for alternate ways to specify the path for the potential file.

As an example, imagine a file SiC.nb3b.harmonic has potential values for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following pair_coeff command:

```
pair_coeff * * SiC.nb3b.harmonic Si Si Si C
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the potential file. The final C argument maps LAMMPS atom type 4 to the C element in the potential file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when the potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials. An example of a pair_coeff command for use with the hybrid pair style is:

```
pair_coeff * * nb3b/harmonic MgOH.nb3b.harmonic Mg O H
```

Three-body non-bonded harmonic files in the potentials directory of the LAMMPS distribution have a “.nb3b.harmonic” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements.

Each entry has six arguments. The first three are atom types as referenced in the LAMMPS input file. The first argument specifies the central atom. The fourth argument indicates the $K$ parameter. The fifth argument indicates $\theta_0$. The sixth argument indicates a separation cutoff in Angstroms.

For a given entry, if the second and third arguments are identical, then the entry is for a cutoff for the distance between types 1 and 2 (values for $K$ and $\theta_0$ are irrelevant in this case).

For a given entry, if the first three arguments are all different, then the entry is for the $K$ and $\theta_0$ parameters (the cutoff in this case is irrelevant).

It is required that the potential file contains entries for all permutations of the elements listed in the pair_coeff command. If certain combinations are not parameterized the corresponding parameters should be set to zero. The potential file can also contain entries for additional elements which are not used in a particular simulation; LAMMPS ignores those entries.
19.182.4 Restrictions

This pair style can only be used if LAMMPS was built with the MANYBODY package. See the Build package page for more info.

pair_coeff 1 1 0.01 4.4 7.0 6.0
```

19.186.3 Description

Style nm computes site-site interactions based on the N-M potential by Clarke, mainly used for ionic liquids. A site can represent a single atom or a united-atom site. The energy of an interaction has the following form:

\[
E = \frac{E_0}{n-m} \left[ m \left( \frac{r_0}{r} \right)^n - n \left( \frac{r_0}{r} \right)^m \right] \quad r < r_c
\]

where \( r_c \) is the cutoff and \( r_0 \) is the minimum of the potential. Please note that this differs from the convention used for other Lennard-Jones potentials in LAMMPS where \( \sigma \) represents the location where the energy is zero.

Style nm/cut/split applies the standard LJ (12-6) potential above \( r_0 = 2^{\frac{1}{6}} \sigma \). Style nm/cut/split is employed in polymer equilibration protocols that combine core-softening approaches with topology-changing moves Dietz.

Style nm/cut/coul/cut adds a Coulombic pairwise interaction given by

\[
E = \frac{Cq_i q_j}{\epsilon r} \quad r < r_c
\]

where \( C \) is an energy-conversion constant, \( q_i \) and \( q_j \) are the charges on the 2 atoms, and epsilon is the dielectric constant which can be set by the dielectric command. If one cutoff is specified in the pair_style command, it is used for both the N-M and Coulombic terms. If two cutoffs are specified, they are used as cutoffs for the N-M and Coulombic terms respectively.

Styles nm/cut/coul/long compute the same Coulombic interactions as style nm/cut/coul/cut except that an additional damping factor is applied to the Coulombic term so it can be used in conjunction with the kspace_style command and its ewald or pppm option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

For all of the nm pair styles, the following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands.

- \( E_0 \) (energy units)
- \( r_0 \) (distance units)
- \( n \) (unitless)
- \( m \) (unitless)
• cutoff1 (distance units)
• cutoff2 (distance units)

The latter 2 coefficients are optional. If not specified, the global N-M and Coulombic cutoffs specified in the pair_style command are used. If only one cutoff is specified, it is used as the cutoff for both N-M and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the N-M and Coulombic cutoffs for this type pair. You cannot specify 2 cutoffs for style nm, since it has no Coulombic terms.

For nm/cut/coul/long only the N-M cutoff can be specified since a Coulombic cutoff cannot be specified for an individual IJ type pair. All type pairs use the same global Coulombic cutoff specified in the pair_style command.

19.186.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

All of the nm pair styles supports the pair_modify shift option for the energy of the pair interaction.

The nm/cut/coul/long pair styles support the pair_modify table option since they can tabulate the short-range portion of the long-range Coulombic interaction.

All of the nm pair styles support the pair_modify tail option for adding a long-range tail correction to the energy and pressure for the N-M portion of the pair interaction.

All of the nm pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

All of the nm pair styles can only be used via the pair keyword of the run_style respa command. They do not support the inner, middle, outer keywords.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

19.186.5 Restrictions

These pair styles are part of the EXTRA-PAIR package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.
19.186.6 Related commands

pair_coeff, pair_style lj/cut, bond style fene/nm

19.186.7 Default

none

19.187 pair_style none command

19.187.1 Syntax

```
pair_style none
```

19.187.2 Examples

```
pair_style none
```

19.187.3 Description

Using a pair style of none means that any previous pair style setting will be deleted and pairwise forces and energies are not computed.

As a consequence there will be a pairwise force cutoff of 0.0, which has implications for the default setting of the neighbor list and the communication cutoff. Those are the sum of the largest pairwise cutoff and the neighbor skin distance (see the documentation of the neighbor command and the comm_modify command). When you have bonds, angles, dihedrals, or impropers defined at the same time, you must set the communication cutoff so that communication cutoff distance is large enough to acquire and communicate sufficient ghost atoms from neighboring sub-domains as needed for computing bonds, angles, etc.

A pair style of none will also not request a pairwise neighbor list. However if the neighbor style is bin, data structures for binning are still allocated. If the neighbor list cutoff is small, then these data structures can consume a large amount of memory. So you should either set the neighbor style to nsq or set the skin distance to a larger value.

See the pair_style zero for a way to set a pairwise cutoff and thus trigger the building of a neighbor lists and setting a corresponding communication cutoff, but compute no pairwise interactions.
19.187.4 Restrictions

You must not use a **pair_coeff** command with this pair style. Since there is no interaction computed, you cannot set any coefficients for it.

19.192.3 Description

The oxdna pair styles compute the pairwise-additive parts of the oxDNA force field for coarse-grained modelling of DNA. The effective interaction between the nucleotides consists of potentials for the excluded volume interaction oxdna/excv, the stacking oxdna/stk, cross-stacking oxdna/xstk and coaxial stacking interaction oxdna/coaxstk as well as the hydrogen-bonding interaction oxdna/hbond between complementary pairs of nucleotides on opposite strands. Average sequence or sequence-dependent stacking and base-pairing strengths are supported (Sulc). Quasi-unique base-pairing between nucleotides can be achieved by using more complementary pairs of atom types like 5-8 and 6-7, 9-12 and 10-11, 13-16 and 14-15, etc. This prevents the hybridization of in principle complementary bases within Ntypes/4 bases up and down along the backbone.

The exact functional form of the pair styles is rather complex. The individual potentials consist of products of modulation factors, which themselves are constructed from a number of more basic potentials (Morse, Lennard-Jones, harmonic angle and distance) as well as quadratic smoothing and modulation terms. We refer to (Ouldridge-DPhil) and (Ouldridge) for a detailed description of the oxDNA force field.

Note: These pair styles have to be used together with the related oxDNA bond style oxdna/fene for the connectivity of the phosphate backbone (see also documentation of bond_style oxdna/fene). Most of the coefficients in the above example have to be kept fixed and cannot be changed without reparameterizing the entire model. Exceptions are the first four coefficients after oxdna/stk (seq=seqdep, T=0.1, xi=1.3448 and kappa=2.6568 in the above example) and the first coefficient after oxdna/hbond (seq=seqdep in the above example). When using a Langevin thermostat, e.g. through fix langevin or fix nve/dotr/langevin the temperature coefficients have to be matched to the one used in the fix.

Note: These pair styles have to be used with the atom_style hybrid bond ellipsoid oxdna (see documentation of atom_style). The atom_style oxdna stores the 3’-to-5’ polarity of the nucleotide strand, which is set through the bond topology in the data file. The first (second) atom in a bond definition is understood to point towards the 3’-end (5’-end) of the strand.

Example input and data files for DNA duplexes can be found in examples/PACKAGES/cgdna/examples/oxDNA/ and /oxDNA2/. A simple python setup tool which creates single straight or helical DNA strands, DNA duplexes or arrays of DNA duplexes can be found in examples/PACKAGES/cgdna/util/.
Please cite *(Henrich)* in any publication that uses this implementation. An updated documentation that contains general information on the model, its implementation and performance as well as the structure of the data and input file can be found here.

Please cite also the relevant oxDNA publications *(Ouldridge), (Ouldridge-DPhil)* and *(Sulc)*.

### 19.204.3 Description

The oxrna2 pair styles compute the pairwise-additive parts of the oxDNA force field for coarse-grained modelling of DNA. The effective interaction between the nucleotides consists of potentials for the excluded volume interaction oxrna2/excv, the stacking oxrna2/stk, cross-stacking oxrna2/xstk and coaxial stacking interaction oxrna2/coaxstk, electrostatic Debye-Hueckel interaction oxrna2/dh as well as the hydrogen-bonding interaction oxrna2/hbond between complementary pairs of nucleotides on opposite strands. Average sequence or sequence-dependent stacking and base-pairing strengths are supported (Sulc2). Quasi-unique base-pairing between nucleotides can be achieved by using more complementary pairs of atom types like 5-8 and 6-7, 9-12 and 10-11, 13-16 and 14-15, etc. This prevents the hybridization of in principle complementary bases within Ntypes/4 bases up and down along the backbone.

The exact functional form of the pair styles is rather complex. The individual potentials consist of products of modulation factors, which themselves are constructed from a number of more basic potentials (Morse, Lennard-Jones, harmonic angle and distance) as well as quadratic smoothing and modulation terms. We refer to (Sulc) and the original oxDNA publications (Ouldridge-DPhil) and (Ouldridge) for a detailed description of the oxRNA2 force field.
**Note:** These pair styles have to be used together with the related oxDNA2 bond style *oxrna2/fene* for the connectivity of the phosphate backbone (see also documentation of *bond_style oxrna2/fene*). Most of the coefficients in the above example have to be kept fixed and cannot be changed without reparameterizing the entire model. Exceptions are the first four coefficients after *oxrna2/stk* (seq=seqdep, T=0.1, xi=1.40206 and kappa=2.77 in the above example), the first coefficient after *oxrna2/hbond* (seq=seqdep in the above example) and the three coefficients after *oxrna2/dh* (T=0.1, rhos=0.5, qeff=1.02455 in the above example). When using a Langevin thermostat e.g. through *fix langevin* or *fix nve/dotc/langevin* the temperature coefficients have to be matched to the one used in the fix.

**Note:** These pair styles have to be used with the *atom_style hybrid bond ellipsoid oxdna* (see documentation of *atom_style*). The *atom_style oxdna* stores the 3’-to-5’ polarity of the nucleotide strand, which is set through the bond topology in the data file. The first (second) atom in a bond definition is understood to point towards the 3’-end (5’-end) of the strand.

Example input and data files for DNA duplexes can be found in examples/PACKAGES/cgdna/examples/oxDNA/ and /oxDNA2/. A simple python setup tool which creates single straight or helical DNA strands, DNA duplexes or arrays of DNA duplexes can be found in examples/PACKAGES/cgdna/util/.

Please cite *(Henrich)* in any publication that uses this implementation. The article contains general information on the model, its implementation and performance as well as the structure of the data and input file. The preprint version of the article can be found [here](#). Please cite also the relevant oxRNA2 publications *(Sulc1)* and *(Sulc2)*.

### 19.204.4 Restrictions

These pair styles can only be used if LAMMPS was built with the CG-DNA package and the MOLECULE and AS-PHERE package. See the *Build package* page for more info.

### 19.204.6 Default

none

19.205 pair_style pace command

Accelerator Variants: pace/kk

19.205.1 Syntax

```
pair_style pace ... keyword values ...
```

- one or more keyword/value pairs may be appended

  keyword = product or recursive or chunksize
  product = use product algorithm for basis functions
  recursive = use recursive algorithm for basis functions
  chunksize value = number of atoms in each pass

19.205.2 Examples

```
pair_style pace
pair_style pace product chunksize 2048
pair_coeff * * Cu-PBE-core-rep.ace Cu
```

19.205.3 Description

Pair style `pace` computes interactions using the Atomic Cluster Expansion (ACE), which is a general expansion of the atomic energy in multi-body basis functions. (Drautz). The `pace` pair style provides an efficient implementation that is described in this paper (Lysogorskiy).

In ACE, the total energy is decomposed into a sum over atomic energies. The energy of atom $i$ is expressed as a linear or non-linear function of one or more density functions. By projecting the density onto a local atomic base, the lowest order contributions to the energy can be expressed as a set of scalar polynomials in basis function contributions summed over neighbor atoms.

Only a single pair_coeff command is used with the `pace` style which specifies an ACE coefficient file followed by N additional arguments specifying the mapping of ACE elements to LAMMPS atom types, where N is the number of LAMMPS atom types:

- ACE coefficient file
- N element names = mapping of ACE elements to atom types

Only a single pair_coeff command is used with the `pace` style which specifies an ACE file that fully defines the potential. Note that unlike for other potentials, cutoffs are not set in the pair_style or pair_coeff command; they are specified in the ACE file.

The pair_style `pace` command may be followed by the optional keyword product or recursive, which determines which of two algorithms is used for the calculation of basis functions and derivatives. The default is recursive.

The keyword chunksize is only applicable when using the pair style `pace` with the KOKKOS package on GPUs and is ignored otherwise. This keyword controls the number of atoms in each pass used to compute the atomic cluster expansion and is used to avoid running out of memory. For example if there are 8192 atoms in the simulation and the chunksize is set to 4096, the ACE calculation will be broken up into two passes (running on a single GPU).

See the pair_coeff page for alternate ways to specify the path for the ACE coefficient file.
19.205.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I !≠ J, where types I and J correspond to two different element types, mixing is performed by LAMMPS with user-specifiable parameters as described above. You never need to specify a pair_coeff command with I !≠ J arguments for this style.

This pair style does not support the \texttt{pair\_modify} shift, table, and tail options.

This pair style does not write its information to \textit{binary restart files}, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the \texttt{pair} keyword of the \texttt{run\_style\ respa} command. It does not support the \texttt{inner}, \texttt{middle}, \texttt{outer} keywords.

Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

19.205.5 Restrictions

This pair style is part of the ML-PACE package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

19.205.6 Related commands

19.209.3 Description

The peridynamic pair styles implement material models that can be used at the mesoscopic and macroscopic scales. See this document for an overview of LAMMPS commands for Peridynamics modeling.

Style peri/pmb implements the Peridynamic bond-based prototype microelastic brittle (PMB) model.

Style peri/lps implements the Peridynamic state-based linear peridynamic solid (LPS) model.

Style peri/ves implements the Peridynamic state-based linear peridynamic viscoelastic solid (VES) model.

Style peri/eps implements the Peridynamic state-based elastic-plastic solid (EPS) model.

The canonical papers on Peridynamics are (Silling 2000) and (Silling 2007). The implementation of Peridynamics in LAMMPS is described in (Parks). Also see the PDLAMMPS user guide for more details about its implementation.
The peridynamic VES and EPS models in PDLAMMPS were implemented by R. Rahman and J. T. Foster at University of Texas at San Antonio. The original VES formulation is described in “(Mitchell2011)” and the original EPS formulation is in “(Mitchell2011a)”. Additional PDF docs that describe the VES and EPS implementations are include in the LAMMPS distribution in doc/PDF/PDLammps_VES.pdf and doc/PDF/PDLammps_EPS.pdf. For questions regarding the VES and EPS models in LAMMPS you can contact R. Rahman (rezwanur.rahman at utsa.edu).

The following coefficients must be defined for each pair of atom types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below.

For the \texttt{peri/pmb} style:

\begin{itemize}
\item $c$ (energy/distance/volume^2 units)
\item horizon (distance units)
\item s00 (unitless)
\item $\alpha$ (unitless)
\end{itemize}

\noindent $c$ is the effectively a spring constant for Peridynamic bonds, the horizon is a cutoff distance for truncating interactions, and s00 and $\alpha$ are used as a bond breaking criteria. The units of $c$ are such that $c/distance = stiffness/volume^2$, where stiffness is energy/distance^2 and volume is distance^3. See the users guide for more details.

For the \texttt{peri/lps} style:

\begin{itemize}
\item $K$ (force/area units)
\item $G$ (force/area units)
\item horizon (distance units)
\item s00 (unitless)
\item $\alpha$ (unitless)
\end{itemize}

\noindent $K$ is the bulk modulus and $G$ is the shear modulus. The horizon is a cutoff distance for truncating interactions, and s00 and $\alpha$ are used as a bond breaking criteria. See the users guide for more details.

For the \texttt{peri/ves} style:

\begin{itemize}
\item $K$ (force/area units)
\item $G$ (force/area units)
\item horizon (distance units)
\item s00 (unitless)
\item $\alpha$ (unitless)
\item $m_{\lambda}$ (unitless)
\item $m_{\tau}$ (unitless)
\end{itemize}

\noindent $K$ is the bulk modulus and $G$ is the shear modulus. The horizon is a cutoff distance for truncating interactions, and s00 and $\alpha$ are used as a bond breaking criteria. \textit{m}_{\lambda} and \textit{m}_{\tau} are the viscoelastic relaxation parameter and time constant, respectively. \textit{m}_{\lambda} varies within zero to one. For very small values of \textit{m}_{\lambda} the viscoelastic model responds very similar to a linear elastic model. For details please see the description in “(Mitchell2011)”.

For the \texttt{peri/eps} style:

\begin{itemize}
\item $K$ (force/area units)
\item $G$ (force/area units)
\item horizon (distance units)
\end{itemize}
• \(s00\) (unitless)
• \(\alpha\) (unitless)
• \(m\text{\_yield\_stress}\) (force/area units)

\(K\) is the bulk modulus and \(G\) is the shear modulus. The horizon is a cutoff distance and \(s00\) and \(\alpha\) are used as a bond breaking criteria. \(m\_yield\_stress\) is the yield stress of the material. For details please see the description in "(Mitchell2011a)".

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Accelerator packages} page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \textit{-suffix} command-line switch when you invoke LAMMPS, or you can use the \textit{suffix} command in your input script.

See the \textit{Accelerator packages} page for more instructions on how to use the accelerated styles effectively.

### 19.209.4 Mixing, shift, table, tail correction, restart, rRESPA info

These pair styles do not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

These pair styles do not support the \textit{pair\_modify} shift option.

The \textit{pair\_modify} table and tail options are not relevant for these pair styles.

These pair styles write their information to \textit{binary restart files}, so \textit{pair\_style} and \textit{pair\_coeff} commands do not need to be specified in an input script that reads a restart file.

These pair styles can only be used via the \textit{pair} keyword of the \textit{run\_style respa} command. They do not support the \textit{inner}, \textit{middle}, \textit{outer} keywords.

### 19.209.5 Restrictions

All of these styles are part of the PERI package. They are only enabled if LAMMPS was built with that package. See the \textit{Build package} page for more info.

### 19.209.6 Related commands

\textit{pair\_coeff}
19.209.7 Default

none

19.210 pair_style polymorphic command

19.210.1 Syntax

```
pair_style polymorphic
```

style = polymorphic

19.210.2 Examples

```
pair_style polymorphic
pair_coeff * * FeCH_BOP_I.poly Fe C H
pair_coeff * * TlBr_msw.poly Tl Br
pair_coeff * * CuTa_eam.poly Cu Ta
pair_coeff * * GaN_tersoff.poly Ga N
pair_coeff * * GaN_sw.poly Ga N
```

19.210.3 Description

The polymorphic pair style computes a 3-body free-form potential \((Zhou3)\) for the energy \(E\) of a system of atoms as

\[
E = \frac{1}{2} \sum_{i=1}^{N} \sum_{j=1}^{N} \left[ (1 - \delta_{ij}) \cdot U_{IJ} \left( r_{ij} \right) - (1 - \eta_{ij}) \cdot F_{IJ} \left( X_{ij} \right) \cdot V_{IJ} \left( r_{ij} \right) \right]
\]

\[
X_{ij} = \sum_{k=i_1,k\neq j}^{i_N} W_{IK} \left( r_{ik} \right) \cdot G_{JK} \left( \cos \theta_{jik} \right) \cdot P_{JIK} \left( \Delta r_{jik} \right)
\]

\[
\Delta r_{jik} = r_{ij} - \xi_{IJ} \cdot r_{ik}
\]

where I, J, K represent species of atoms i, j, and k, \(i_1, ..., i_N\) represents a list of i’s neighbors, \(\delta_{ij}\) is a Dirac constant (i.e., \(\delta_{ij} = 1\) when \(i = j\), and \(\delta_{ij} = 0\) otherwise), \(\eta_{ij}\) is similar constant that can be set either to \(\eta_{ij} = \delta_{ij}\) or \(\eta_{ij} = 1 - \delta_{ij}\) depending on the potential type, \(U_{IJ}(r_{ij}), V_{IJ}(r_{ij}), W_{IK}(r_{ik})\) are pair functions, \(G_{JK}(\cos \theta_{jik})\) is an angular function, \(P_{JIK}(\Delta r_{jik})\) is a function of atomic spacing differential \(\Delta r_{jik} = r_{ij} - \xi_{IJ} \cdot r_{ik}\) with \(\xi_{IJ}\) being a pair-dependent parameter, and \(F_{IJ}(X_{ij})\) is a function of the local environment variable \(X_{ij}\). This generic potential

2168 Chapter 19. Pair Styles
is fully defined once the constants $\eta_{ij}$ and $\xi_{ij}$, and the six functions $U_{IJ}(r_{ij})$, $V_{IJ}(r_{ij})$, $W_{IK}(r_{ik})$, $G_{JIK}(\cos \theta_{jik})$, $P_{JIK}(\Delta r_{jik})$, and $F_{IJ}(X_{ij})$ are given. Here LAMMPS uses a global parameter $\eta$ to represent $\eta_{ij}$. When $\eta = 1$, $\eta_{ij} = 1 - \delta_{ij}$, otherwise $\eta = \delta_{ij}$. Additionally, $\eta = 3$ indicates that the function $P_{JIK}(\Delta r)$ depends on species I, J and K, otherwise $P_{JIK}(\Delta r) = P_{IK}(\Delta r)$ only depends on species I and K. Note that these six functions are all one dimensional, and hence can be provided in a tabular form. This allows users to design different potentials solely based on a manipulation of these functions. For instance, the potential reduces to a Stillinger-Weber potential (SW) if we set

$$
\eta_{ij} = \delta_{ij}(\eta = 2 \text{ or } \eta = 0), \xi_{IJ} = 0
$$

$$
U_{IJ}(r) = A_{IJ} \cdot \epsilon_{IJ} \cdot \left(\frac{\sigma_{IJ}}{r}\right)^q \cdot \left[B_{IJ} \cdot \left(\frac{\sigma_{IJ}}{r}\right)^{p-q} - 1\right] \cdot \exp \left[\frac{\sigma_{IJ}}{r - a_{IJ} \cdot \sigma_{IJ}}\right]
$$

$$
V_{IJ}(r) = \sqrt{\lambda_{IJ} \cdot \epsilon_{IJ} IJ} \cdot \exp \left[\frac{\gamma_{IJ} \cdot \sigma_{IJ}}{r - a_{IJ} \cdot \sigma_{IJ}}\right]
$$

$$
F_{IJ}(X) = -X
$$

$$
P_{JIK}(\Delta r) = P_{IK}(\Delta r) = 1
$$

$$
W_{IJ}(r) = \sqrt{\lambda_{IJ} \cdot \epsilon_{IJ} IJ} \cdot \exp \left[\frac{\gamma_{IJ} \cdot \sigma_{IJ}}{r - a_{IJ} \cdot \sigma_{IJ}}\right]
$$

$$
G_{JIK}(\cos \theta) = \left(\cos \theta + \frac{1}{3}\right)^2
$$

The potential reduces to a Tersoff potential (Tersoff or Albe) if we set

$$
\eta_{ij} = \delta_{ij}(\eta = 2 \text{ or } \eta = 0), \xi_{IJ} = 1
$$

$$
U_{IJ}(r) = \frac{D_{e,IJ}}{S_{IJ} - 1} \cdot \exp \left[-\beta_{IJ} \sqrt{2 S_{IJ}} (r - r_{e,IJ})\right] \cdot f_{c,IJ}(r)
$$

$$
V_{IJ}(r) = \frac{S_{IJ} \cdot D_{e,IJ}}{S_{IJ} - 1} \cdot \exp \left[-\beta_{IJ} \sqrt{\frac{2}{S_{IJ}} (r - r_{e,IJ})}\right] \cdot f_{c,IJ}(r)
$$

$$
F_{IJ}(X) = (1 + X)^{-\frac{1}{2}}
$$

$$
P_{JIK}(\Delta r) = P_{IK}(\Delta r) = \exp (2 \mu_{IK} \cdot \Delta r)
$$

$$
W_{IJ}(r) = f_{c,IJ}(r)
$$

$$
G_{JIK}(\cos \theta) = \gamma_{IK} \left[1 + \frac{e_{IK}^2}{d_{IK}^2} - \frac{e_{IK}^2}{d_{IK}^2 + (h_{IK} + \cos \theta)^2}\right]
$$

where

$$
f_{c,IJ}(r) = \begin{cases} 
1, & r \leq R_{IJ} - D_{IJ} \\
\frac{1}{2} + \frac{1}{2} \cos \left[\frac{\pi (r + D_{IJ} - R_{IJ})}{2 R_{IJ}}\right], & R_{IJ} - D_{IJ} < r < R_{IJ} + D_{IJ} \\
0, & r \geq R_{IJ} + D_{IJ}
\end{cases}
$$

The potential reduces to a modified Stillinger-Weber potential (Zhou3) if we set

$$
\eta_{ij} = \delta_{ij}(\eta = 2 \text{ or } \eta = 0), \xi_{IJ} = 0
$$

$$
U_{IJ}(r) = \varphi_{R,IJ}(r) - \varphi_{A,IJ}(r)
$$

$$
V_{IJ}(r) = u_{IJ}(r)
$$

$$
F_{IJ}(X) = -X
$$

$$
P_{JIK}(\Delta r) = P_{IK}(\Delta r) = 1
$$

$$
W_{IJ}(r) = u_{IJ}(r)
$$

$$
G_{JIK}(\cos \theta) = g_{JIK}(\cos \theta)
$$
The potential reduces to a Rockett-Tersoff potential (Wang3) if we set
\[ \xi_{iJ} = 1 \]
\[ U_{IJ} (r) = A_{I} \exp \left( -\lambda_{1,1J} \cdot r \right) f_{c,IJ} (r) f_{ca,IJ} (r) \]
\[ V_{IJ} (r) = \left\{ \begin{array}{l} B_{I} \exp \left( -\lambda_{2,1J} \cdot r \right) f_{c,IJ} (r) + A_{I} \exp \left( -\lambda_{1,1J} \cdot r \right) f_{c,IJ} (r) [1 - f_{ca,IJ} (r)] \\ \end{array} \right\} \]
\[ F_{IJ} (X) = [1 + (\beta_{I} X)^{n_{I}}]^{-\frac{1}{n_{I}}} \]
\[ P_{JIK} (\Delta r) = P_{IK} (\Delta r) = \exp (\lambda_{3,IK} \cdot \Delta r^{3}) \]
\[ W_{IJ} (r) = f_{c,IJ} (r) \]
\[ G_{JIK} (\cos \theta) = 1 + \frac{c_{1JK}^{2}}{d_{2JK}^{2}} - \frac{c_{2JK}^{2}}{d_{2JK}^{2} + (h_{JK} + \cos \theta)^{2}} \]
where \( f_{ca,IJ} (r) \) is similar to the \( f_{c,IJ} (r) \) defined above:
\[ f_{ca,IJ} (r) = \begin{cases} 1, & r \leq R_{a,IJ} - D_{a,IJ} \\ \frac{1}{2} + \frac{1}{2} \cos \left[ \frac{\pi (r + D_{a,IJ} - R_{a,IJ})}{2 D_{a,IJ}} \right], & 0, r > R_{a,IJ} + D_{a,IJ} \end{cases} \]

The potential becomes the embedded atom method (Daw) if we set
\[ \xi_{iJ} = 0 \]
\[ U_{I} (r) = \phi_{I} \left( r \right) \]
\[ V_{I} (r) = 1 \]
\[ F_{I} (X) = -2 F_{I} (X) \]
\[ P_{IJK} (\Delta r) = P_{IK} (\Delta r) = 1 \]
\[ W_{I} (r) = f_{I} (r) \]
\[ G_{IJK} (\cos \theta) = 1 \]

In the embedded atom method case, \( \phi_{I} (r) \) is the pair energy, \( F_{I} (X) \) is the embedding energy, \( X \) is the local electron density, and \( f_{I} (r) \) is the atomic electron density function.

The potential reduces to another type of Tersoff potential (Zhou4) if we set
\[ \xi_{iJ} = 1 \]
\[ U_{I} (r) = \frac{D_{e,IJ}}{S_{I} - 1} \cdot \exp \left[ -\beta_{IJ} \sqrt{2 S_{IJ}} (r - r_{e,IJ}) \right] \cdot f_{c,IJ} (r) \cdot T_{IJ} (r) + V_{ZBL,IJ} (r) [1 - T_{IJ} (r)] \]
\[ V_{I} (r) = \frac{S_{I} \cdot D_{e,IJ}}{S_{I} - 1} \cdot \exp \left[ -\beta_{IJ} \sqrt{2 S_{IJ}} (r - r_{e,IJ}) \right] \cdot f_{c,IJ} (r) \cdot T_{IJ} (r) \]
\[ F_{I} (X) = (1 + X)^{-\frac{1}{2}} \]
\[ P_{IJK} (\Delta r) = \omega_{IJK} \cdot \exp (\alpha_{IJK} \cdot \Delta r) \]
\[ W_{I} (r) = f_{c,IJ} (r) \]
\[ G_{IJK} (\cos \theta) = \gamma_{IJK} \left[ 1 + \frac{c_{2JK}^{2}}{d_{2JK}^{2}} - \frac{c_{2JK}^{2}}{d_{2JK}^{2} + (h_{JK} + \cos \theta)^{2}} \right] \]
\[ T_{IJ} (r) = \frac{1}{1 + \exp \left[ -b_{f,IJ} (r - r_{f,IJ}) \right]} \]
\[ V_{ZBL,IJ} (r) = 14.4 \cdot \frac{Z_{I} \cdot Z_{J}}{r} \sum_{k=1}^{4} \mu_{k} \cdot \exp \left[ -\nu_{k} \left( Z_{I}^{0.23} + Z_{J}^{0.23} \right) r \right] \]

where \( f_{c,IJ} (r) \) is the same as defined above. This Tersoff potential differs from the one above because the \( P_{JIK} (\Delta r) \) function is now dependent on all three species I, J, and K.
If the tabulated functions are created using the parameters of Stillinger-Weber, Tersoff, and EAM potentials, the polymorphic pair style will produce the same global properties (energies and stresses) and the same forces as the sw, tersoff, and eam pair styles. The polymorphic pair style also produces the same per-atom properties (energies and stresses) as the corresponding tersoff and eam pair styles. However, due to a different partitioning of global properties to per-atom properties, the polymorphic pair style will produce different per-atom properties (energies and stresses) as the sw pair style. This does not mean that polymorphic pair style is different from the sw pair style. It just means that the definitions of the atom energies and atom stresses are different.

Only a single pair_coeff command is used with the polymorphic pair style which specifies a potential file for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of polymorphic potential elements to atom types

See the pair_coeff page for alternate ways to specify the path for the potential file. Several files for polymorphic potentials are included in the potentials directory of the LAMMPS distribution. They have a “poly” suffix.

As an example, imagine the GaN_tersoff.poly file has tabulated functions for Ga-N tersoff potential. If your LAMMPS simulation has 4 atom types and you want the first 3 to be Ga, and the fourth to be N, you would use the following pair_coeff command:

```
pair_coeff * * GaN_tersoff.poly Ga Ga Ga N
```

The first two arguments must be * * to span all pairs of LAMMPS atom types. The first three Ga arguments map LAMMPS atom types 1,2,3 to the Ga element in the polymorphic file. The final N argument maps LAMMPS atom type 4 to the N element in the polymorphic file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when an polymorphic potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Potential files in the potentials directory of the LAMMPS distribution have a “.poly” suffix. At the beginning of the files, an unlimited number of lines starting with ‘#’ are used to describe the potential and are ignored by LAMMPS. The next line lists two numbers:

```
ntypes eta
```

Here ntypes represent total number of species defined in the potential file, $\eta = 1$ reduces to embedded atom method, $\eta = 3$ assumes a three species dependent $P_{JK}(\Delta r)$ function, and all other values of $\eta$ assume a two species dependent $P_{JK}(\Delta r)$ function. The value of ntypes must equal the total number of different species defined in the pair_coeff command. The next ntypes lines each lists two numbers and a character string representing atomic number, atomic mass, and name of the species of the ntypes elements:

```
atomic-number atomic-mass element-name(1)
atomic-number atomic-mass element-name(2)
...  
atomic-number atomic-mass element-name(ntypes)
```

The next line contains four numbers:

```
nr ntheta nx xmax
```

Here nr is total number of tabular points for radial functions U, V, W, P, ntheta is total number of tabular points for the angular function G, nx is total number of tabular points for the function F, xmax is a maximum value of the argument of function F. Note that the pair functions $U_{I,J}(r)$, $V_{I,J}(r)$, $W_{I,J}(r)$ are uniformly tabulated between 0 and cutoff distance of the JJ pair, $G_{IJK}(\cos \theta)$ is uniformly tabulated between -1 and 1, $P_{IJK}(\Delta r)$ is uniformly tabulated between -rcmax and rcmax where rcmax is the maximum cutoff distance of all pairs, and $F_{I,J}(X)$ is uniformly tabulated between 0 and xmax. Linear extrapolation is assumed if actual simulations exceed these ranges.
The next ntypes*(ntypes+1)/2 lines contain two numbers:

cut xi(1)
cut xi(2)
...
cut xi(ntypes*(ntypes+1)/2)

Here cut means the cutoff distance of the pair functions, “xi” is ξ as defined in the potential functions above. The ntypes*(ntypes+1)/2 lines are related to the pairs according to the sequence of first ii (self) pairs, i = 1, 2, ..., ntypes, and then ij (cross) pairs, i = 1, 2, ..., ntypes-1, and j = i+1, i+2, ..., ntypes (i.e., the sequence of the ij pairs follows 11, 22, ..., 12, 13, 14, ..., 23, 24, ...).

In the final blocks of the potential file, U, V, W, P, G, and F functions are listed sequentially. First, U functions are given for each of the ntypes*(ntypes+1)/2 pairs according to the sequence described above. For each of the pairs, nr values are listed. Next, similar arrays are given for V and W functions. If P functions depend only on pair species, i.e., η ≠ 3, then P functions are also listed the same way the next. If P functions depend on three species, i.e., η = 3, then P functions are listed for all the ntypes*ntypes*ntypes IJK triplets in a natural sequence I from 1 to ntypes, J from 1 to ntypes, and K from 1 to ntypes (i.e., IJK = 111, 112, 113, ..., 121, 122, 123, ..., 211, 212, ...). Next, G functions are listed for all the ntypes*ntypes*ntypes IJK triplets similarly. For each of the G functions, ntheta values are listed. Finally, F functions are listed for all the ntypes*(ntypes+1)/2 pairs in the same sequence as described above. For each of the F functions, nx values are listed.

19.210.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write their information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

19.210.5 Restrictions

If using create_atoms command, atomic masses must be defined in the input script. If using read_data, atomic masses must be defined in the atomic structure data file.

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This pair potential requires the newton setting to be “on” for pair interactions.

The potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use any LAMMPS units, but you would need to create your own potential files.

19.210.6 Related commands

pair_coeff

19.211 pair_style python command

pair_coeff * * coul/long
pair_coeff * * python py_pot.LJCutSPCE OW NULL
```

19.211.3 Description

The `python` pair style provides a way to define pairwise additive potential functions as python script code that is loaded into LAMMPS from a python file which must contain specific python class definitions. This allows to rapidly evaluate different potential functions without having to modify and re-compile LAMMPS. Due to python being an interpreted language, however, the performance of this pair style is going to be significantly slower (often between 20x and 100x) than corresponding compiled code. This penalty can be significantly reduced through generating tabulations from the python code through the `pair_write` command, which is supported by this style.

Only a single `pair_coeff` command is used with the `python` pair style which specifies a python class inside a python module or a file that LAMMPS will look up in the current directory, a folder pointed to by the `LAMMPS_POTENTIALS` environment variable or somewhere in your python path. A single python module can hold multiple python pair class definitions. The class definitions itself have to follow specific rules that are explained below.

Atom types in the python class are specified through symbolic constants, typically strings. These are mapped to LAMMPS atom types by specifying N additional arguments after the class name in the `pair_coeff` command, where N must be the number of currently defined atom types:

As an example, imagine a file `py_pot.py` has a python potential class names `LJCutMelt` with parameters and potential functions for a two Lennard-Jones atom types labeled as ‘LJ1’ and ‘LJ2’. In your LAMMPS input and you would have defined 3 atom types, out of which the first two are supposed to be using the ‘LJ1’ parameters and the third the ‘LJ2’ parameters, then you would use the following `pair_coeff` command:

```plaintext
pair_coeff * * py_pot.LJCutMelt LJ1 LJ1 LJ2
```
The first two arguments **must** be \*\* so as to span all LAMMPS atom types. The first two LJ1 arguments map LAMMPS atom types 1 and 2 to the LJ1 atom type in the LJCutMelt class of the py_pot.py file. The final LJ2 argument maps LAMMPS atom type 3 to the LJ2 atom type the python file. If a mapping value is specified as NULL, the mapping is not performed, any pair interaction with this atom type will be skipped. This can be used when a *python* potential is used as part of the *hybrid* or *hybrid/overlay* pair style. The NULL values are then placeholders for atom types that will be used with other potentials.

The python potential file has to start with the following code:

```python
from __future__ import print_function

class LAMMSPairPotential(object):
    def __init__(self):
        self.pmap=dict()
        self.units='lj'
    def map_coeff(self,name,ltype):
        self.pmap[ltype]=name
    def check_units(self,units):
        if (units != self.units):
            raise Exception("Conflicting units: %s vs. %s" % (self.units,units))
```

Any classes with definitions of specific potentials have to be derived from this class and should be initialize in a similar fashion to the example given below.

**Note:** The class constructor has to set up a data structure containing the potential parameters supported by this class. It should also define a variable `self.units` containing a string matching one of the options of LAMMPS’ `units` command, which is used to verify, that the potential definition in the python class and in the LAMMPS input match.

Here is an example for a single type Lennard-Jones potential class `LJCutMelt` in reduced units, which defines an atom type `lj` for which the parameters epsilon and sigma are both 1.0:

```python
class LJCutMelt(LAMMSPairPotential):
    def __init__(self):
        super(LJCutMelt,self).__init__()
        # set coeffs: 48*eps*sig**12, 24*eps*sig**6,
        #       4*eps*sig**12, 4*eps*sig**6
        self.units = 'lj'
        self.coeff = {'lj' : {'lj' : (48.0,24.0,4.0,4.0)}}
```

The class also has to provide two methods for the computation of the potential energy and forces, which have be named `compute_force`, and `compute_energy`, which both take 3 numerical arguments:

- `rsq` = the square of the distance between a pair of atoms (float)
- `itype` = the (numerical) type of the first atom
- `jtype` = the (numerical) type of the second atom

This functions need to compute the (scaled) force and the energy, respectively, and use the result as return value. The functions need to use the `pmap` dictionary to convert the LAMMPS atom type number to the symbolic value of the internal potential parameter data structure. Following the `LJCutMelt` example, here are the two functions:
def compute_force(self, rsq, itype, jtype):
    coeff = self.coeff[self.pmap[itype]][self.pmap[jtype]]
    r2inv = 1.0/rsq
    r6inv = r2inv*r2inv*r2inv
    lj1 = coeff[0]
    lj2 = coeff[1]
    return (r6inv * (lj1*r6inv - lj2))*r2inv

def compute_energy(self, rsq, itype, jtype):
    coeff = self.coeff[self.pmap[itype]][self.pmap[jtype]]
    r2inv = 1.0/rsq
    r6inv = r2inv*r2inv*r2inv
    lj3 = coeff[2]
    lj4 = coeff[3]
    return (r6inv * (lj3*r6inv - lj4))

Note: for consistency with the C++ pair styles in LAMMPS, the compute_force function follows the conventions of the Pair::single() methods and does not return the pairwise force directly, but the force divided by the distance between the two atoms, so this value only needs to be multiplied by delta x, delta y, and delta z to conveniently obtain the three components of the force vector between these two atoms.

Below is a more complex example using real units and defines an interaction equivalent to:

```plaintext
units real
pair_style harmonic/cut
pair_coeff 1 1 0.2 9.0
pair_coeff 2 2 0.4 9.0
```

This uses the default geometric mixing. The equivalent input with pair style python is:

```plaintext
units real
pair_style python 10.0
pair_coeff * * py_pot.Harmonic A B
```

Note that while for pair style harmonic/cut the cutoff is implicitly set to the minimum of the harmonic potential, for pair style python a global cutoff must be set and it must be equal or larger to the implicit cutoff of the potential in python, which has to explicitly return zero force and energy beyond the cutoff. Also, the mixed parameters have to be explicitly provided. The corresponding python code is:

```python
class Harmonic(LAMMPSPairPotential):
    def __init__(self):
        super(Harmonic,self).__init__()
        self.units = 'real'
        # set coeffs: K, r0
        self.coeff = {'A' : {'A' : (0.2,9.0),
                              'B' : (math.sqrt(0.2*0.4),9.0),
                             'B' : (0.4,9.0))}

    def compute_force(self, rsq, itype, jtype):
        coeff = self.coeff[self.pmap[itype]][self.pmap[jtype]]
        r = math.sqrt(rsq)
        (continues on next page)```
delta = coeff[1]-r
if (r < coeff[1]):
    return 2.0*delta*coeff[0]/r
else:
    return 0.0

def compute_energy(self,rsq,itype,jtype):
    coeff = self.coeff[self.pmap[itype]][self.pmap[jtype]]
    r = math.sqrt(rsq)
    delta = coeff[1]-r
    if (r < coeff[1]):
        return delta*delta*coeff[0]
    else:
        return 0.0

Performance Impact
The evaluation of scripted python code will slow down the computation of pairwise interactions quite significantly. However, this performance penalty can be worked around through using the python pair style not for the actual simulation, but to generate tabulated potentials using the pair_write command. This will also enable GPU or multi-thread acceleration through the GPU, KOKKOS, or OPENMP package versions of the table pair style. Please see below for a LAMMPS input example demonstrating how to build a table file:

```plaintext
pair_style  python 2.5
pair_coeff  * * py_pot.LJCutMelt lj
shell rm -f lj.table
pair_write 1 1 2000 rsq 0.01 2.5 lj.table lj
```

Note that it is strongly recommended to try to delete the potential table file before generating it. Since the pair_write command will always append to a table file, while pair style table will use the first match. Thus when changing the potential function in the python class, the table pair style will still read the old variant unless the table file is first deleted.

After switching the pair style to table, the potential tables need to be assigned to the LAMMPS atom types like this:

```plaintext
pair_style  table linear 2000
pair_coeff  1 1 lj.table lj
```

This can also be done for more complex systems. Please see the examples/python folders for a few more examples.

19.211.4 Mixing, shift, table, tail correction, restart, rRESPA info
Mixing of potential parameters has to be handled inside the provided python module. The python pair style simply assumes that force and energy computation can be correctly performed for all pairs of atom types as they are mapped to the atom type labels inside the python potential class.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.
This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

### 19.211.5 Restrictions

This pair style is part of the PYTHON package. It is only enabled if LAMMPS was built with that package. See the `Build package` page for more info.

### 19.211.6 Related commands

`pair_coeff`, `pair_write`, `pair style table`

### 19.211.7 Default

`none`

### 19.212 pair_style quip command

#### 19.212.1 Syntax

```
pair_style quip
```

#### 19.212.2 Examples

```
pair_style quip
pair_coeff * * gap_example.xml "Potential xml_label=GAP_2014_5_8_60_17_10_38_466" 14
pair_coeff * * sw_example.xml "IP SW" 14
```

#### 19.212.3 Description

Style `quip` provides an interface for calling potential routines from the QUIP package. QUIP is built separately, and then linked to LAMMPS. The most recent version of the QUIP package can be downloaded from GitHub: [https://github.com/libAtoms/QUIP](https://github.com/libAtoms/QUIP). The interface is chiefly intended to be used to run Gaussian Approximation Potentials (GAP), which are described in the following publications: *(Bartok et al)* and *(PhD thesis of Bartok)*.

Only a single `pair_coeff` command is used with the `quip` style that specifies a QUIP potential file containing the parameters of the potential for all needed elements in XML format. This is followed by a QUIP initialization string. Finally, the QUIP elements are mapped to LAMMPS atom types by specifying N atomic numbers, where N is the number of LAMMPS atom types:

- QUIP filename
- QUIP initialization string
- N atomic numbers = mapping of QUIP elements to atom types
See the `pair_coeff` page for alternate ways to specify the path for the potential file.

A QUIP potential is fully specified by the filename which contains the parameters of the potential in XML format, the initialization string, and the map of atomic numbers.

GAP potentials can be obtained from the Data repository section of http://www.libatoms.org, where the appropriate initialization strings are also advised. The list of atomic numbers must be matched to the LAMMPS atom types specified in the LAMMPS data file or elsewhere.

Two examples input scripts are provided in the examples/PACKAGES/quip directory.

### 19.212.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the `pair_modify` mix, shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

### 19.212.5 Restrictions

This pair style is part of the ML-QUIP package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

QUIP potentials are parameterized in electron-volts and Angstroms and therefore should be used with LAMMPS metal units.

QUIP potentials are generally not designed to work with the scaling factors set by the `special_bonds` command. The recommended setting in molecular systems is to include all interactions, i.e. to use `special_bonds lj/coul 1.0 1.0 1.0`. Scaling factors > 0.0 will be ignored and treated as 1.0. The only exception to this rule is if you know that your QUIP potential needs to exclude bonded, 1-3, or 1-4 interactions and does not already do this exclusion within QUIP. Then a factor 0.0 needs to be used which will remove such pairs from the neighbor list. This needs to be very carefully tested, because it may remove pairs from the neighbor list that are still required.

### 19.212.6 Related commands

`pair_coeff`

### 19.213 pair_style rann command

#### 19.213.1 Syntax

```
pair_style rann
pair_coeff file Type1_element Type2_element Type3_element...
```
19.213.2 Examples

```
pair_style rann
pair_coeff ** Mg.rann Mg
pair_coeff ** MgAlalloy.rann Mg Mg Al Mg
```

19.213.3 Description

Pair style *rann* computes pairwise interactions for a variety of materials using rapid atomistic neural network (RANN) potentials ([Dickel](#), [Nitol](#)). Neural network potentials work by first generating a series of symmetry functions i.e. structural fingerprints from the neighbor list and then using these values as the input layer of a neural network. There is a single output neuron in the final layer which is the energy. Atomic forces are found by analytical derivatives computed via back-propagation. For alloy systems, each element has a unique network.

19.213.4 Potential file syntax

The RANN potential is defined by a single text file which contains all the fitting parameters for the alloy system. The potential file also defines the active fingerprints, network architecture, activation functions, etc. The potential file is divided into several sections which are identified by one of the following keywords:

- atomtypes
- mass
- fingerprintsperatom
- fingerprints
- fingerprintconstants
- screening (optional)
- networklayers
- layersize
- weight
- bias
- activationfunctions
- calibrationparameters (ignored)

The ‘#’ character is treated as a comment marker, similar to LAMMPS input scripts. Sections are not required to follow a rigid ordering, but do require previous definition of prerequisite information. E.g., fingerprintconstants for a particular fingerprint must follow the fingerprints definition; layersize for a particular layer must follow the declaration of network layers.

*atomtypes* are defined as follows using element keywords separated by spaces.

```
atomtypes:
Fe Mg Al etc.
```

*mass* must be specified for each element keyword as follows:
mass:Mg:
 24.305
mass:Fe:
 55.847
mass:Al:
 26.982

*fingerprints per element* specifies how many fingerprints are active for computing the energy of a given atom. This number must be specified for each element keyword. Active elements for each fingerprint depend upon the type of the central atom and the neighboring atoms. Pairwise fingerprints may be defined for a Mg atom based exclusively on its Al neighbors, for example. Bond fingerprints may use two neighbor lists of different element types. In computing fingerprints per element from all defined fingerprints, only the fingerprints defined for atoms of a particular element should be considered, regardless of the elements used in its neighbor list. In the following code, for example, some fingerprints may compute pairwise fingerprints summing contributions about Fe atoms based on a neighbor list of exclusively Al atoms, but if there are no fingerprints summing contributions of all neighbors about a central Al atom, then fingerprints per element of Al is zero:

```plaintext
fingerprints per element: Mg:
  5
fingerprints per element: Fe:
  2
fingerprints per element: Al:
  0
```

*fingerprints* specifies the active fingerprints for a certain element combination. Pair fingerprints are specified for two elements, while bond fingerprints are specified for three elements. Only one fingerprints header should be used for an individual combination of elements. The ordering of the fingerprints in the network input layer is determined by the order of element combinations specified by subsequent *fingerprints* lines, and the order of the fingerprints defined for each element combination. Multiple fingerprints of the same style or different ones may be specified. If the same style and element combination is used for multiple fingerprints, they should have different id numbers. The first element specifies the atoms for which this fingerprint is computed while the other(s) specify which atoms to use in the neighbor lists for the computation. Switching the second and third element type in bond fingerprints has no effect on the computation:

```plaintext
fingerprints: Mg_Mg:
 radial_0 radial_screened_0 radial_1
fingerprints: Mg_Al_Fe:
 bond_0 bond_screened_0
fingerprints: Mg_Al:
 radial_0 radial_screened_0
```

The following fingerprint styles are currently defined. See the *formulation section* below for their definitions:

- radial
- radial_screened
- radial_spin
- radial_screened_spin
- bond
- bond_screened
- bond_spin
- bond_screened_spin
**fingerprintconstants** specifies the meta-parameters for a defined fingerprint. For all radial styles, re, rc, alpha, dr, o, and n must be specified. re should usually be the stable interatomic distance, rc is the cutoff radius, dr is the cutoff smoothing distance, o is the lowest radial power term (which may be negative), and n is the highest power term. The total length of the fingerprint vector is \( (n-o+1) \). alpha is a list of decay parameters used for exponential decay of radial contributions. It may be set proportionally to the bulk modulus similarly to MEAM potentials, but other values may provided better fitting in special cases. Bond style fingerprints require specification of re, rc, alphak, dr, k, and m. Here m is the power of the bond cosines and k is the number of decay parameters. Cosine powers go from 0 to m-1 and are each computed for all values of alphak. Thus the total length of the fingerprint vector is \( m*k \).

```
fingerprintconstants:Mg_Mg:radialscreened_0:re: 3.193592
fingerprintconstants:Mg_Mg:radialscreened_0:rc: 6.000000
fingerprintconstants:Mg_Mg:radialscreened_0:alpha: 5.520000 5.520000 5.520000 5.520000
fingerprintconstants:Mg_Mg:radialscreened_0:dr: 2.806408
fingerprintconstants:Mg_Mg:radialscreened_0:o: -1
fingerprintconstants:Mg_Mg:radialscreened_0:n: 3
```

**screening** specifies the Cmax and Cmin values used in the screening fingerprints. Contributions form neighbors to the fingerprint are omitted if they are blocked by a closer neighbor, and reduced if they are partially blocked. Larger values of Cmin correspond to neighbors being blocked more easily. Cmax cannot be greater than 3, and Cmin cannot be greater than Cmax or less than zero. Screening may be omitted in which case the default values Cmax = 2.8, Cmin = 0.8 are used. Since screening is a bond computation, it is specified separately for each combination of three elements in which the latter two may be interchanged with no effect.

```
screening:Mg_Mg_Mg:Cmax: 2.700000
screening:Mg_Mg_Mg:Cmin: 0.400000
```

**networklayers** species the size of the neural network for each atom. It counts both the input and output layer and so is 2 + <hidden layers>.

```
networklayers:Mg: 3
```

**layersize** specifies the length of each layer, including the input layer and output layer. The input layer is layer 0. The size of the input layer size must match the summed length of all the fingerprints for that element, and the output layer size must be 1:

```
layersize:Mg:0: 14
layersize:Mg:1: 20
layersize:Mg:2: 1
```

**weight** specifies the weight for a given element and layer. Weight cannot be specified for the output layer. The weight of layer i is a \( m x n \) matrix where m is the layer size of i and n is the layer size of i+1:

```
```
weight:Mg:0:
w11 w12 w13 ...
w21 w22 w23 ...
...

Bias specifies the bias for a given element and layer. Bias cannot be specified for the output layer. The bias of layer $i$ is a $n \times 1$ vector where $n$ is the layer size of $i+1$:

bias:Mg:0:
b1
b2
b3
...

Activation functions specify the activation function for a given element and layer. Activation functions cannot be specified for the output layer:

activationfunctions:Mg:0:
sigI

activationfunctions:Mg:1:
linear

The following activation styles are currently specified. See the formulation section below for their definitions.

- sigI
- linear

Calibration parameters specify a number of parameters used to calibrate the potential. These are ignored by LAMMPS.

## 19.213.5 Formulation

In the RANN formulation, the total energy of a system of atoms is given by:

$$E = \sum_{\alpha} E^\alpha$$

$$E^\alpha = N A^\alpha$$

$${}^{n+1}A_i^\alpha = ^n F \left(^n W_{ij} {}^n A_j^\alpha + {}^n B_i \right)$$

$${}^0 A_i^\alpha = \begin{bmatrix} 1 S_f^\alpha \\ 2 S_f^\alpha \\ \vdots \end{bmatrix}$$

Here $E^\alpha$ is the energy of atom $\alpha$, $^n F()$, $^n W_{ij}$ and $^n B_i$ are the activation function, weight matrix and bias vector of the $n$-th layer respectively. The inputs to the first layer are a collection of structural fingerprints which are collected and reshaped into a single long vector. The individual fingerprints may be defined in any order and have various shapes and sizes. Multiple fingerprints of the same type and varying parameters may also be defined in the input layer.

Eight types of structural fingerprints are currently defined. In the following, $\beta$ and $\gamma$ span the full neighbor list of atom $\alpha$. $\delta_i$ are decay meta-parameters, and $r_c$ is a meta-parameter roughly proportional to the first neighbor distance. $r_c$ and $dr$ are the neighbor cutoff distance and cutoff smoothing distance respectively. $S^{\alpha\beta}$ is the MEAM screening function.
\( s^\alpha_i \) and \( s^\beta_i \) are the atom spin vectors \( \text{Tranchida} \). \( r^{\alpha\beta} \) is the distance from atom \( \alpha \) to atom \( \beta \), and \( \theta^{\alpha\beta\gamma} \) is the bond angle:

\[
\cos(\theta^{\alpha\beta\gamma}) = \frac{r^{\alpha\beta} \cdot r^{\alpha\gamma}}{r^{\alpha\beta} r^{\alpha\gamma}}
\]

\( S^{\alpha\beta} \) is defined as \( \text{Baskes} \):

\[
X^{\gamma\beta} = \left( \frac{r^{\gamma\beta}}{r^{\alpha\beta}} \right)^2
\]

\[
X^{\alpha\gamma} = \left( \frac{r^{\alpha\gamma}}{r^{\alpha\beta}} \right)^2
\]

\[
C = \frac{2 (X^{\alpha\gamma} + X^{\gamma\beta}) - (X^{\alpha\gamma} - X^{\gamma\beta})^2}{1 - (X^{\alpha\gamma} - X^{\gamma\beta})^2}
\]

\[
f_c(x) = \begin{cases} 
1 & x \geq 1 \\
\left(1 - (1 - x)^4\right)^2 & 0 < x < 1 \\
0 & x \leq 0 
\end{cases}
\]

\[
S^{\alpha\beta\gamma} = f_c \left( \frac{C - C_{\text{min}}}{C_{\text{max}} - C_{\text{min}}} \right)
\]

\[
S^{\alpha\beta} = \prod_\gamma S^{\alpha\beta\gamma}
\]

The structural fingerprints are computed as follows:

- **radial**

\[
r^{\alpha\beta}_i = \sum_\beta \left( \frac{r^{\alpha\beta}}{r_c} \right)^i e^{-\delta_i \frac{r^{\alpha\beta}}{r_c}} f_c \left( \frac{r_c - r^{\alpha\beta}}{dr} \right)
\]

- **bond**

\[
b^{\alpha\beta\gamma}_i = \sum_\beta \sum_\gamma (\cos(\theta^{\alpha\beta\gamma}))^i e^{-\delta_j \frac{r^{\alpha\beta}}{r_c}} e^{-\delta_j \frac{r^{\alpha\gamma}}{r_c}} f_c \left( \frac{r_c - r^{\alpha\beta}}{dr} \right) f_c \left( \frac{r_c - r^{\alpha\gamma}}{dr} \right)
\]

- **radialscreened**

\[
r^{\alpha\beta\gamma}_i = \sum_\beta \left( \frac{r^{\alpha\beta}}{r_c} \right)^i e^{-\delta_i \frac{r^{\alpha\beta}}{r_c}} S^{\alpha\beta} f_c \left( \frac{r_c - r^{\alpha\beta}}{dr} \right)
\]

- **bondscreened**

\[
b^{\alpha\beta\gamma}_i = \sum_\beta \sum_\gamma (\cos(\theta^{\alpha\beta\gamma}))^i e^{-\delta_j \frac{r^{\alpha\beta}}{r_c}} e^{-\delta_j \frac{r^{\alpha\gamma}}{r_c}} S^{\alpha\beta} S^{\alpha\gamma} f_c \left( \frac{r_c - r^{\alpha\beta}}{dr} \right) f_c \left( \frac{r_c - r^{\alpha\gamma}}{dr} \right)
\]

- **radialspin**

\[
r^{\alpha\beta\gamma}_i = \sum_\beta \left( \frac{r^{\alpha\beta}}{r_c} \right)^i e^{-\delta_i \frac{r^{\alpha\beta}}{r_c}} (s^\alpha \cdot s^\beta) f_c \left( \frac{r_c - r^{\alpha\beta}}{dr} \right)
\]
• bondspins

\[ \text{bsp} S_{ij}^\alpha = \sum_\beta \sum_\gamma (\cos(\theta_{\alpha\beta\gamma}))^i e^{-\delta_j r_{\alpha\beta}^c} e^{-\delta_j r_{\alpha\gamma}^c} (s_\alpha \cdot s_\beta) (s_\alpha \cdot s_\gamma) f_c \left( \frac{r_c - r_{\alpha\beta}^c}{dr} \right) f_c \left( \frac{r_c - r_{\alpha\gamma}^c}{dr} \right) \]

• radialscreenedspin

\[ \text{rscsp} S_i^\alpha = \sum_\beta \left( \frac{r_{\alpha\beta}^c}{r_c} \right)^i e^{-\delta_i r_{\alpha\beta}^c} S_{\alpha\beta} (s_\alpha \cdot s_\beta) f_c \left( \frac{r_c - r_{\alpha\beta}^c}{dr} \right) \]

• bondscreenedspin

\[ \text{bscsp} S_{ij}^\alpha = \sum_\beta \sum_\gamma (\cos(\theta_{\alpha\beta\gamma}))^i e^{-\delta_j r_{\alpha\beta}^c} e^{-\delta_j r_{\alpha\gamma}^c} S_{\alpha\beta} S_{\alpha\gamma} (s_\alpha \cdot s_\beta) (s_\alpha \cdot s_\gamma) f_c \left( \frac{r_c - r_{\alpha\beta}^c}{dr} \right) f_c \left( \frac{r_c - r_{\alpha\gamma}^c}{dr} \right) \]

The activation functions are computed as follows:

• sig

\[ F^{\text{sig}}(x) = 0.1x + 0.9 \ln (e^x + 1) \]

• linear

\[ F^{\text{linear}}(x) = x \]

19.213.6 Restrictions

Pair style ran is part of the ML-RANN package. It is only enabled if LAMMPS was built with that package. Additionally, if any spin fingerprint styles are used LAMMPS must be built with the SPIN package as well.

Pair style ran does not support computing per-atom stress or using pair_modify nofdotr.

19.213.7 Defaults

\[ \text{Cmin} = 0.8, \ \text{Cmax} = 2.8. \]

(Baskes) Baskes, Materials Chemistry and Physics, 50(2), 152-158, (1997).

19.214 pair_style reaxff command

Accelerator Variants: reaxff/kk, reaxff/omp
19.214.1 Syntax

```
pair_style reaxff cfile keyword value
```

- cfile = NULL or name of a control file
- zero or more keyword/value pairs may be appended

  - keyword = checkqeq or lgvdw or safezone or mincap or minhbonds or tabulate or listblocking
  - checkqeq value = yes or no = whether or not to require qeq/reaxff or acks2/reaxff
  - lgvdw value = yes or no = whether or not to use a low gradient vdW correction
  - safezone = factor used for array allocation
  - mincap = minimum size for array allocation
  - minhbonds = minimum size use for storing hydrogen bonds
  - tabulate value = size of interpolation table for Lennard-Jones and Coulombinteractions
  - list/blocking value = yes or no = whether or not to use “blocking” scheme for bond list build

19.214.2 Examples

```
pair_style reaxff NULL
pair_style reaxff controlfile checkqeq no
pair_style reaxff NULL lgvdw yes
pair_style reaxff NULL safezone 1.6 mincap 100
pair_coeff * * ffield.reax C H O N
```

19.214.3 Description

Style reaxff computes the ReaxFF potential of van Duin, Goddard and co-workers. ReaxFF uses distance-dependent bond-order functions to represent the contributions of chemical bonding to the potential energy. There is more than one version of ReaxFF. The version implemented in LAMMPS uses the functional forms documented in the supplemental information of the following paper: (Chenoweth et al., 2008). The version integrated into LAMMPS matches the version of ReaxFF From Summer 2010. For more technical details about the pair reaxff implementation of ReaxFF, see the (Aktulga) paper. The reaxff style was initially implemented as a stand-alone C code and is now converted to C++ and integrated into LAMMPS as a package.

The reaxff/kk style is a Kokkos version of the ReaxFF potential that is derived from the reaxff style. The Kokkos version can run on GPUs and can also use OpenMP multithreading. For more information about the Kokkos package, see Packages details and Speed kokkos doc pages. One important consideration when using the reaxff/kk style is the choice of either half or full neighbor lists. This setting can be changed using the Kokkos package command.

The reaxff style differs from the (obsolete) “pair_style reax” command in the implementation details. The reax style was a Fortran library, linked to LAMMPS. The reax style has been removed from LAMMPS after the 12 December 2018 version.

LAMMPS provides several different versions of ffield.reax in its potentials dir, each called potentials/ffield.reax.label. These are documented in potentials/README.reax. The default ffield.reax contains parameterizations for the following elements: C, H, O, N.
The format of these files is identical to that used originally by van Duin. We have tested the accuracy of `pair_style reaxff` potential against the original ReaxFF code for the systems mentioned above. You can use other ffield files for specific chemical systems that may be available elsewhere (but note that their accuracy may not have been tested).

**Note:** We do not distribute a wide variety of ReaxFF force field files with LAMMPS. Adri van Duin’s group at PSU is the central repository for this kind of data as they are continuously deriving and updating parameterizations for different classes of materials. You can submit a contact request at the Materials Computation Center (MCC) website [https://www.mri.psu.edu/materials-computation-center/connect-mcc](https://www.mri.psu.edu/materials-computation-center/connect-mcc), describing the material(s) you are interested in modeling with ReaxFF. They can tell you what is currently available or what it would take to create a suitable ReaxFF parameterization.

The `cfile` setting can be specified as NULL, in which case default settings are used. A control file can be specified which defines values of control variables. Some control variables are global parameters for the ReaxFF potential. Others define certain performance and output settings. Each line in the control file specifies the value for a control variable. The format of the control file is described below.

**Note:** The LAMMPS default values for the ReaxFF global parameters correspond to those used by Adri van Duin’s stand-alone serial code. If these are changed by setting control variables in the control file, the results from LAMMPS and the serial code will not agree.

Examples using `pair_style reaxff` are provided in the examples/reax sub-directory.

Use of this pair style requires that a charge be defined for every atom. See the `atom_style` and `read_data` commands for details on how to specify charges.

The ReaxFF parameter files provided were created using a charge equilibration (QEq) model for handling the electrostatic interactions. Therefore, by default, LAMMPS requires that either the `fix qeq/reaxff` or the `fix qeq/shielded` or `fix acks2/reaxff` command be used with `pair_style reaxff` when simulating a ReaxFF model, to equilibrate the charges each timestep.

Using the keyword `checkqeq` with the value `no` turns off the check for the QEq fixes, allowing a simulation to be run without charge equilibration. In this case, the static charges you assign to each atom will be used for computing the electrostatic interactions in the system. See the `fix qeq/reaxff` or `fix qeq/shielded` or `fix acks2/reaxff` command documentation for more details.

Using the optional keyword `lgvdw` with the value `yes` turns on the low-gradient correction of ReaxFF for long-range London Dispersion, as described in the (Liu) paper. The bundled force field file `ffield.reax.lg` is designed for this correction, and is trained for several energetic materials (see “Liu”). When using `lgvdw yes`, the recommended value for parameter `thb` is 0.01, which can be set in the control file. Note: Force field files are different for the original or lg corrected pair styles, using the wrong ffield file generates an error.

Using the optional keyword `enobonds` with the value `yes`, the energy of atoms with no bonds (i.e. isolated atoms) is included in the total potential energy and the per-atom energy of that atom. If the value `no` is specified then the energy of atoms with no bonds is set to zero. The latter behavior is usual not desired, as it causes discontinuities in the potential energy when the bonding of an atom drops to zero.

Optional keywords `safezone`, `mincap`, and `minhbonds` are used for allocating reaxff arrays. Increasing these values can avoid memory problems, such as segmentation faults and bondchk failed errors, that could occur under certain conditions. These keywords are not used by the Kokkos version, which instead uses a more robust memory allocation scheme that checks if the sizes of the arrays have been exceeded and automatically allocates more memory.

The keyword `tabulate` controls the size of interpolation table for Lennard-Jones and Coulomb interactions. Tabulation may also be set in the control file (see below). If tabulation is set in both the input script and the control file, the value in the control file will be ignored. A size of 10000 is typically used for the interpolation table. A value of 0 means no tabulation will be used.
The keyword *list/blocking* is only supported by the Kokkos version of ReaxFF and ignored otherwise. Setting the value to *yes* enables the “blocking” scheme (dynamically building interaction lists) for the ReaxFF bond neighbor list. This reduces the number of empty interactions and can improve performance in some cases (e.g., large number of atoms/GPU on AMD hardware). It is also enabled by default when running the CPU with Kokkos.

The thermo variable \textit{evdwl} stores the sum of all the ReaxFF potential energy contributions, with the exception of the Coulombic and charge equilibration contributions which are stored in the thermo variable \textit{ecoul}. The output of these quantities is controlled by the \textit{thermo} command.

This pair style tallies a breakdown of the total ReaxFF potential energy into sub-categories, which can be accessed via the \textbf{compute pair} command as a vector of values of length 14. The 14 values correspond to the following sub-categories (the variable names in italics match those used in the original FORTRAN ReaxFF code):

1. \textit{eb} = bond energy
2. \textit{ea} = atom energy
3. \textit{elp} = lone-pair energy
4. \textit{emol} = molecule energy (always 0.0)
5. \textit{ev} = valence angle energy
6. \textit{epen} = double-bond valence angle penalty
7. \textit{ecoa} = valence angle conjugation energy
8. \textit{ehb} = hydrogen bond energy
9. \textit{et} = torsion energy
10. \textit{eco} = conjugation energy
11. \textit{ew} = van der Waals energy
12. \textit{ep} = Coulomb energy
13. \textit{efi} = electric field energy (always 0.0)
14. \textit{eqeq} = charge equilibration energy

To print these quantities to the log file (with descriptive column headings) the following commands could be included in an input script:

```plaintext
compute reax all pair reaxff
variable eb equal c_reax[1]
variable ea equal c_reax[2]
[...]
variable eqeq equal c_reax[14]
thermo_style custom step temp epair v_eb v_ea [...] v_eqeq
```

Only a single pair\_coeff command is used with the \textit{reaxff} style which specifies a ReaxFF potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair\_coeff command, where N is the number of LAMMPS atom types:

- \textit{filename}
- \textit{N indices} = ReaxFF elements

The filename is the ReaxFF potential file.

In the ReaxFF potential file, near the top, after the general parameters, is the atomic parameters section that contains element names, each with a couple dozen numeric parameters. If there are M elements specified in the \textit{ffield} file, think of these as numbered 1 to M. Each of the N indices you specify for the N atom types of LAMMPS atoms must be an integer from 1 to M. Atoms with LAMMPS type 1 will be mapped to whatever element you specify as the first index.
value, etc. If a mapping value is specified as NULL, the mapping is not performed. This can be used when the *reaxff* style is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

As an example, say your LAMMPS simulation has 4 atom types and the elements are ordered as C, H, O, N in the *ffield* file. If you want the LAMMPS atom type 1 and 2 to be C, type 3 to be N, and type 4 to be H, you would use the following pair_coeff command:

```
pair_coeff * * ffield.reax C C N H
```

### 19.214.4 Control file

The format of a line in the control file is as follows:

```
variable_name value
```

and it may be followed by an “!” character and a trailing comment.

If the value of a control variable is not specified, then default values are used. What follows is the list of variables along with a brief description of their use and default values.

- **simulation_name**  Output files produced by *pair_style reaxff* carry this name + extensions specific to their contents. Partial energies are reported with a “.pot” extension, while the trajectory file has “.trj” extension.

- **tabulate_long_range**  To improve performance, long range interactions can optionally be tabulated (0 means no tabulation). Value of this variable denotes the size of the long range interaction table. The range from 0 to long range cutoff (defined in the *ffield* file) is divided into *tabulate_long_range* points. Then at the start of simulation, we fill in the entries of the long range interaction table by computing the energies and forces resulting from van der Waals and Coulomb interactions between every possible atom type pairs present in the input system. During the simulation we consult to the long range interaction table to estimate the energy and forces between a pair of atoms. Linear interpolation is used for estimation. (default value = 0)

- **energy_update_freq**  Denotes the frequency (in number of steps) of writes into the partial energies file. (default value = 0)

- **nbrhood_cutoff**  Denotes the near neighbors cutoff (in Angstroms) regarding the bonded interactions. (default value = 5.0)

- **hbond_cutoff**  Denotes the cutoff distance (in Angstroms) for hydrogen bond interactions. (default value = 7.5. A value of 0.0 turns off hydrogen bonds)

- **bond_graph_cutoff**  is the threshold used in determining what is a physical bond, what is not. Bonds and angles reported in the trajectory file rely on this cutoff. (default value = 0.3)

- **thb_cutoff**  cutoff value for the strength of bonds to be considered in three body interactions. (default value = 0.001)

- **thb_cutoff_sq**  cutoff value for the strength of bond order products to be considered in three body interactions. (default value = 0.00001)

- **write_freq**  Frequency of writes into the trajectory file. (default value = 0)

- **traj_title**  Title of the trajectory - not the name of the trajectory file.

- **atom_info**  1 means print only atomic positions + charge (default = 0)

- **atom_forces**  1 adds net forces to atom lines in the trajectory file (default = 0)

- **atom_velocities**  1 adds atomic velocities to atoms line (default = 0)
**bond_info** 1 prints bonds in the trajectory file (default = 0)

**angle_info** 1 prints angles in the trajectory file (default = 0)

### 19.214.5 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the *pair_modify* mix, shift, table, and tail options.

This pair style does not write its information to *binary restart files*, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the *pair* keyword of the *run_style respa* command. It does not support the *inner, middle, outer* keywords.

Styles with a *gpu, intel, kk, omp, or opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* command-line switch when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

### 19.214.6 Restrictions

This pair style is part of the REAXFF package. It is only enabled if LAMMPS was built with that package. See the *Build package* page for more info.

The ReaxFF potential files provided with LAMMPS in the potentials directory are parameterized for *real units*. You can use the ReaxFF pair style with any LAMMPS units, but you would need to create your own potential file with coefficients listed in the appropriate units if your simulation does not use “real” units.

### 19.214.7 Related commands

`pair_coeff`, `fix qeq/reaxff`, `fix acks2/reaxff`, `fix reaxff/bonds`, `fix reaxff/species`

### 19.214.8 Default

The keyword defaults are checkqeq = yes, enobonds = yes, lgvdw = no, safezone = 1.2, mincap = 50, minhbonds = 25, tabulate = 0, list/blocking = yes on CPU, no on GPU.

19.215 pair_style resquared command

Accelerator Variants: resquared/gpu, resquared/omp

19.215.1 Syntax

```
pair_style resquared cutoff
```

- cutoff = global cutoff for interactions (distance units)

19.215.2 Examples

```
pair_style resquared 10.0
pair_coeff * * 1.0 1.0 1.7 3.4 3.4 1.0 1.0 1.0
```

19.215.3 Description

Style resquared computes the RE-squared anisotropic interaction (Everaers), (Babadi) between pairs of ellipsoidal and/or spherical Lennard-Jones particles. For ellipsoidal interactions, the potential considers the ellipsoid as being comprised of small spheres of size $\sigma$. LJ particles are a single sphere of size $\sigma$. The distinction is made to allow the pair style to make efficient calculations of ellipsoid/solvent interactions.

Details for the equations used are given in the references below and in this supplementary document.

Use of this pair style requires the NVE, NVT, or NPT fixes with the asphere extension (e.g. fix nve/asphere) in order to integrate particle rotation. Additionally, atom_style ellipsoid should be used since it defines the rotational state and the size and shape of each ellipsoidal particle.

The following coefficients must be defined for each pair of atom types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands:

- $A_{12}$ = Energy Prefactor/Hamaker constant (energy units)
- $\sigma$ = atomic interaction diameter (distance units)
- $\epsilon_{i,a}$ = relative well depth of type I for side-to-side interactions
- $\epsilon_{i,b}$ = relative well depth of type I for face-to-face interactions
- $\epsilon_{i,c}$ = relative well depth of type I for end-to-end interactions
- $\epsilon_{j,a}$ = relative well depth of type J for side-to-side interactions
- $\epsilon_{j,b}$ = relative well depth of type J for face-to-face interactions
- $\epsilon_{j,c}$ = relative well depth of type J for end-to-end interactions
- cutoff (distance units)

The parameters used depend on the type of the interacting particles, i.e. ellipsoids or LJ spheres. The type of a particle is determined by the diameters specified for its 3 shape parameters. If all 3 shape parameters = 0.0, then the particle is treated as an LJ sphere. The $\epsilon_{i,a}$ or $\epsilon_{j,a}$ parameters are ignored for LJ spheres. If the 3 shape parameters are > 0.0, then the particle is treated as an ellipsoid (even if the 3 parameters are equal to each other).

$A_{12}$ specifies the energy prefactor which depends on the types of the two interacting particles.
For ellipsoid/ellipsoid interactions, the interaction is computed by the formulas in the supplementary document referenced above. \( A_{12} \) is the Hamaker constant as described in (Everaers). In LJ units:

\[
A_{12} = 4\pi^2 \epsilon_{LJ} (\rho \sigma^3)^2
\]

where \( \rho \) gives the number density of the spherical particles composing the ellipsoids and \( \epsilon_{LJ} \) determines the interaction strength of the spherical particles.

For ellipsoid/LJ sphere interactions, the interaction is also computed by the formulas in the supplementary document referenced above. \( A_{12} \) has a modified form (see here for details):

\[
A_{12} = 4\pi^2 \epsilon_{LJ} (\rho \sigma^3)
\]

For ellipsoid/LJ sphere interactions, a correction to the distance-of-closest approach equation has been implemented to reduce the error from two particles of disparate sizes; see this supplementary document.

For LJ sphere/LJ sphere interactions, the interaction is computed using the standard Lennard-Jones formula, which is much cheaper to compute than the ellipsoidal formulas. \( A_{12} \) is used as epsilon in the standard LJ formula:

\[
A_{12} = \epsilon_{LJ}
\]

and the specified \( \sigma \) is used as the \( \sigma \) in the standard LJ formula.

When one of both of the interacting particles are ellipsoids, then \( \sigma \) specifies the diameter of the continuous distribution of constituent particles within each ellipsoid used to model the RE-squared potential. Note that this is a different meaning for \( \sigma \) than the \texttt{pair_style gayberne} potential uses.

The \( \epsilon_i \) and \( \epsilon_j \) coefficients are defined for atom types, not for pairs of atom types. Thus, in a series of \texttt{pair_coeff} commands, they only need to be specified once for each atom type.

Specifically, if any of \( \epsilon_{i,a}, \epsilon_{i,b}, \epsilon_{i,c} \) are non-zero, the three values are assigned to atom type I. If all the \( \epsilon_i \) values are zero, they are ignored. If any of \( \epsilon_{j,a}, \epsilon_{j,b}, \epsilon_{j,c} \) are non-zero, the three values are assigned to atom type J. If all three \( \epsilon_i \) values are zero, they are ignored. Thus the typical way to define the \( \epsilon_i \) and \( \epsilon_j \) coefficients is to list their values in “\texttt{pair_coeff I J}” commands when I = J, but set them to 0.0 when I != J. If you do list them when I != J, you should insure they are consistent with their values in other \texttt{pair_coeff} commands.

Note that if this potential is being used as a sub-style of \texttt{pair_style hybrid}, and there is no “\texttt{pair_coeff I I}” setting made for RE-squared for a particular type I (because I-I interactions are computed by another hybrid pair potential), then you still need to insure the epsilon a,b,c coefficients are assigned to that type in a “\texttt{pair_coeff I J}” command.

For large uniform molecules it has been shown that the \( \epsilon_{*,*} \) energy parameters are approximately representable in terms of local contact curvatures (Everaers):

\[
\epsilon_a = \sigma \cdot \frac{a}{b \cdot c}; \epsilon_b = \sigma \cdot \frac{b}{a \cdot c}; \epsilon_c = \sigma \cdot \frac{c}{a \cdot b}
\]

where a, b, and c give the particle diameters.

The last coefficient is optional. If not specified, the global cutoff specified in the \texttt{pair_style} command is used.

Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \texttt{Accelerator packages} page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \texttt{Build package} page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \texttt{-suffix command-line switch} when you invoke LAMMPS, or you can use the \texttt{suffix} command in your input script.

See the \texttt{Accelerator packages} page for more instructions on how to use the accelerated styles effectively.
19.215.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs LJ and I != J, the epsilon and sigma coefficients and cutoff distance can be mixed, but only for sphere pairs. The default mix value is geometric. See the “pair_modify” command for details. Other type pairs cannot be mixed, due to the different meanings of the energy prefactors used to calculate the interactions and the implicit dependence of the ellipsoid-sphere interaction on the equation for the Hamaker constant presented here. Mixing of sigma and epsilon followed by calculation of the energy prefactors using the equations above is recommended.

This pair style supports the pair_modify shift option for the energy of the Lennard-Jones portion of the pair interaction, but only for sphere-sphere interactions. There is no shifting performed for ellipsoidal interactions due to the anisotropic dependence of the interaction.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords of the run_style command.

19.215.5 Restrictions

This style is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This pair style requires that atoms be ellipsoids as defined by the atom_style ellipsoid command.

Particles acted on by the potential can be finite-size aspherical or spherical particles, or point particles. Spherical particles have all 3 of their shape parameters equal to each other. Point particles have all 3 of their shape parameters equal to 0.0.

The distance-of-closest-approach approximation used by LAMMPS becomes less accurate when high-aspect ratio ellipsoids are used.

19.215.6 Related commands

pair_coeff, fix nve/asphere, compute temp/asphere, pair_style gayberne

19.215.7 Default

none

19.216 pair_style saip/metal command

Accelerator Variant: saip/metal/opt

19.216.1 Syntax

```
pair_style [hybrid/overlay ...] saip/metal cutoff tap_flag
```

- `cutoff` = global cutoff (distance units)
- `tap_flag` = 0/1 to turn off/on the taper function

19.216.2 Examples

```
pair_style hybrid/overlay saip/metal 16.0 1
pair_coeff * * saip/metal CHAu.ILP Au C H

pair_style hybrid/overlay eam rebo saip/metal 16.0
pair_coeff 1 1 eam Au_u3.eam Au NULL NULL
pair_coeff * * rebo CH.rebo NULL C H
pair_coeff * * saip/metal CHAu.ILP Au C H
```

19.216.3 Description

The `saip/metal` style computes the registry-dependent interlayer potential (ILP) potential for hetero-junctions formed with hexagonal 2D materials and metal surfaces, as described in (Ouyang6).

\[
E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij}
\]

\[
V_{ij} = \text{Tap}(r_{ij}) \left\{ e^{-\alpha(r_{ij}/\beta - 1)} [\epsilon + f(\rho_{ij}) + f(\rho_{ji})] - \frac{1}{1 + e^{-d(r_{ij}/(sR \cdot r_{eff}^2)) - 1}} \cdot \frac{C_6}{r_{ij}^6} \right\}
\]

\[
\rho_{ij}^2 = r_{ij}^2 - (r_{ij} \cdot n_i)^2
\]

\[
\rho_{ji}^2 = r_{ij}^2 - (r_{ij} \cdot n_j)^2
\]

\[
f(\rho) = Ce^{-(\rho/d)^2}
\]

\[
\text{Tap}(r_{ij}) = 20 \left( \frac{r_{ij}}{R_{cut}} \right)^7 - 70 \left( \frac{r_{ij}}{R_{cut}} \right)^6 + 84 \left( \frac{r_{ij}}{R_{cut}} \right)^5 - 35 \left( \frac{r_{ij}}{R_{cut}} \right)^4 + 1
\]

Where `Tap(r_{ij})` is the taper function which provides a continuous cutoff (up to third derivative) for interatomic separations larger than \( r_c \).

It is important to include all the pairs to build the neighbor list for calculating the normals.

**Note:** To account for the isotropic nature of the isolated gold atom electron cloud, their corresponding normal vectors \( \{bf n\}_i \) are assumed to lie along the interatomic vector \( \{bf r\}_{ij} \). Notably, this assumption is suitable for many bulk material surfaces, for example, for systems possessing s-type valence orbitals or metallic surfaces, whose valence electrons are mostly delocalized, such that their Pauli repulsion with the electrons of adjacent surfaces are isotropic.
Caution should be used in the case of very small gold contacts, for example, nano-clusters, where edge effects may become relevant.

The parameter file (e.g. CHAu.ILP), is intended for use with metal units, with energies in meV. Two additional parameters, \( S \) and \( r_{cut} \) are included in the parameter file. \( S \) is designed to facilitate scaling of energies. \( r_{cut} \) is designed to build the neighbor list for calculating the normals for each atom pair.

**Note:** The parameters presented in the parameter file (e.g. BNCH.ILP), are fitted with taper function by setting the cutoff equal to 16.0 Angstrom. Using different cutoff or taper function should be careful.

This potential must be used in combination with hybrid/overlay. Other interactions can be set to zero using pair_style *none*.

This pair style tallies a breakdown of the total interlayer potential energy into sub-categories, which can be accessed via the `compute pair` command as a vector of values of length 2. The 2 values correspond to the following sub-categories:

1. \( E_{vdW} \) = vdW (attractive) energy
2. \( E_{Rep} \) = Repulsive energy

To print these quantities to the log file (with descriptive column headings) the following commands could be included in an input script:

```plaintext
compute 0 all pair saip/metal
variable Evdw equal c_0[1]
variable Erep equal c_0[2]
thermo_style custom step temp epair v_Erep v_Evdw
```

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 19.216.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair_modify mix, shift, table, and tail options.

This pair style does not write their information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.
19.216.5 Restrictions

This pair style is part of the INTERLAYER package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This pair style requires the newton setting to be on for pair interactions.

The CHAu.ILP potential file provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use this potential with any LAMMPS units, but you would need to create your BNCH.ILP potential file with coefficients listed in the appropriate units, if your simulation does not use metal units.

pair_coeff 1 1 lj9_6 100.0 3.5 12.0
```

19.219.3 Description

The *lj/sdk* styles compute a 9/6, 12/4, or 12/6 Lennard-Jones potential, given by

\[
E = \frac{27}{4} \epsilon \left( \frac{\sigma}{r} \right)^9 - \left( \frac{\sigma}{r} \right)^6 \quad r < r_c
\]

\[
E = \frac{3\sqrt{3}}{2} \epsilon \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^4 \quad r < r_c
\]

\[
E = 4\epsilon \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \quad r < r_c
\]

as required for the SDK Coarse-grained MD parameterization discussed in *(Shinoda)* and *(DeVane)*. Rc is the cutoff.

Style *lj/sdk/coul/long* computes the adds Coulombic interactions with an additional damping factor applied so it can be used in conjunction with the *kspace_style* command and its *ewald* or *pppm* or *pppm/cg* option. The Coulombic cutoff specified for this style means that pairwise interactions within this distance are computed directly; interactions outside that distance are computed in reciprocal space.

The following coefficients must be defined for each pair of atoms types via the *pair_coeff* command as in the examples above, or in the data file or restart files read by the *read_data* or *read_restart* commands, or by mixing as described below:

- cg_type (lj9_6, lj12_4, or lj12_6)
- epsilon (energy units)
- sigma (distance units)
- cutoff1 (distance units)

Note that sigma is defined in the LJ formula as the zero-crossing distance for the potential, not as the energy minimum. The prefactors are chosen so that the potential minimum is at -epsilon.

The latter 2 coefficients are optional. If not specified, the global LJ and Coulombic cutoffs specified in the pair_style command are used. If only one cutoff is specified, it is used as the cutoff for both LJ and Coulombic interactions for this type pair. If both coefficients are specified, they are used as the LJ and Coulombic cutoffs for this type pair.

For *lj/sdk/coul/long* and *lj/sdk/coul/msm* only the LJ cutoff can be specified since a Coulombic cutoff cannot be specified for an individual LJ type pair. All type pairs use the same global Coulombic cutoff specified in the pair_style command.

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages*.
page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

19.219.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distance for all of the lj/sdk pair styles cannot be mixed, since different pairs may have different exponents. So all parameters for all pairs have to be specified explicitly through the “pair_coeff” command. Defining them in a data file is also not supported, due to limitations of that file format.

All of the lj/sdk pair styles support the pair_modify shift option for the energy of the Lennard-Jones portion of the pair interaction.

The lj/sdk/coul/long pair styles support the pair_modify table option since they can tabulate the short-range portion of the long-range Coulombic interaction.

All of the lj/sdk pair styles write their information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

The lj/sdk and lj/cut/coul/long pair styles do not support the use of the inner, middle, and outer keywords of the run_style respa command.

19.219.5 Restrictions

All of the lj/sdk pair styles are part of the CG-SDK package. The lj/sdk/coul/long style also requires the KSPACE package to be built (which is enabled by default). They are only enabled if LAMMPS was built with that package. See the Build package doc page for more info.

19.219.6 Related commands

pair_coeff, angle_style sdk

19.219.7 Default

none

(Shinoda) Shinoda, DeVane, Klein, Mol Sim, 33, 27 (2007).
19.220 pair_style sdpd/taitwater/isothermal command

19.220.1 Syntax

```
pair_style sdpd/taitwater/isothermal temperature viscosity seed
```

- temperature = temperature of the fluid (temperature units)
- viscosity = dynamic viscosity of the fluid (mass*distance/time units)
- seed = random number generator seed (positive integer, optional)

19.220.2 Examples

```
pair_style sdpd/taitwater/isothermal 300. 1. 28681
pair_coeff * 1000.0 1430.0 2.4
```

19.220.3 Description

The sdpd/taitwater/isothermal style computes forces between mesoscopic particles according to the Smoothed Dissipative Particle Dynamics model described in this paper by (Espanol and Revenga) under the following assumptions:

1. The temperature is constant and uniform.
2. The shear viscosity is constant and uniform.
3. The volume viscosity is negligible before the shear viscosity.
4. The Boltzmann constant is negligible before the heat capacity of a single mesoscopic particle of fluid.

The third assumption is true for water in nearly incompressible flows. The fourth holds true for water for any reasonable size one can imagine for a mesoscopic particle.

The pressure forces between particles will be computed according to Tait’s equation of state:

\[
p = B \left( \frac{\rho}{\rho_0} \right)^\gamma - 1 \]

where \(\gamma = 7\) and \(B = \frac{c_0^2 \rho_0}{\gamma}\), with \(\rho_0\) being the reference density and \(c_0\) the reference speed of sound.

The laminar viscosity and the random forces will be computed according to formulas described in (Espanol and Revenga).

**Warning:** Similar to brownian and dpd styles, the newton setting for pairwise interactions needs to be on when running LAMMPS in parallel if you want to ensure linear momentum conservation. Otherwise random forces generated for pairs straddling processor boundary will not be equal and opposite.

**Note:** The actual random seed used will be a mix of what you specify and other parameters like the MPI ranks. This is to ensure that different MPI tasks have distinct seeds.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above.
• $\rho_0$ reference density (mass/volume units)
• $c_0$ reference soundspeed (distance/time units)
• $h$ kernel function cutoff (distance units)

### 19.220.4 Mixing, shift, table, tail correction, restart, rRESPA info

This style does not support mixing. Thus, coefficients for all LJ pairs must be specified explicitly.

This style does not support the `pair_modify` shift, table, and tail options.

This style does not write information to binary restart files. Thus, you need to re-specify the `pair_style` and `pair_coeff` commands in an input script that reads a restart file.

This style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

### 19.220.5 Restrictions

This pair style is part of the DPD-SMOOTH package. It is only enabled if LAMMPS was built with that package. See the [Build package](#) page for more info.

### 19.220.6 Related commands

`pair coeff, pair sph/rhosum, pair sph/taitwater`

### 19.220.7 Default

The default seed is 0 (before mixing).

---

### 19.221 pair_style smatb command

### 19.222 pair_style smatb/single command

#### 19.222.1 Syntax

```
pair_style style args
```

- `style = smatb`
- `args = none`

`smatb`
19.222.2 Examples

pair_style smatb
pair_coeff 1 1 2.88 10.35 4.178 0.210 1.818 4.07293506 4.9883063257983666

19.222.3 Description

The smatb styles compute the Second Moment Approximation to the Tight Binding (Cyrot, Gupta, Rosato), given by

\[ E_i = \sum_{j, R_{ij} \leq R_c} \alpha(R_{ij}) - \sqrt{\sum_{j, R_{ij} \leq R_c} \xi^2(R_{ij})} \]

\( R_{ij} \) is the distance between the atom \( i \) and \( j \). And the two functions \( \alpha (r) \) and \( \xi (r) \) are:

\[ \alpha (r) = \begin{cases} Ae^{-p \left( \frac{r}{R_0} - 1 \right)} & r < R_{sc} \\ a_3 (r - R_c)^3 + a_4 (r - R_c)^4 + a_5 (r - R_c)^5 & R_{sc} < r < R_c \end{cases} \]

\[ \xi (r) = \begin{cases} \xi e^{-q \left( \frac{r}{R_0} - 1 \right)} & r < R_{sc} \\ x_3 (r - R_c)^3 + x_4 (r - R_c)^4 + x_5 (r - R_c)^5 & R_{sc} < r < R_c \end{cases} \]

The polynomial coefficients \( a_3, a_4, a_5, x_3, x_4, x_5 \) are computed by LAMMPS; the two exponential terms and their first and second derivatives are smoothly reduced to zero, from the inner cutoff \( R_{sc} \) to the outer cutoff \( R_c \).

19.222.4 Coefficients

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- \( R_0 \) (distance units)
- \( p \) (dimensionless)
- \( q \) (dimensionless)
- \( A \) (energy units)
- \( \xi \) (energy units)
- \( R_{sc} \) (distance units)
- \( R_c \) (distance units)

Note that: \( R_0 \) is the nearest neighbor distance, usually coincides with the diameter of the atoms

See the run_style command for details.
19.222.5 Mixing info

For atom type pairs I,J and I != J the coefficients are not automatically mixed.

19.222.6 Restrictions

This pair style is part of the SMTBQ package and is only enabled if LAMMPS is built with that package. See the Build package page for more info.

These pair potentials require the newton setting to be “on” for pair interactions.

19.222.7 Related commands

19.223 pair_style smd/hertz command

19.223.1 Syntax

pair_style smd/hertz scale_factor

19.223.2 Examples

pair_style smd/hertz 1.0
pair_coeff 1 1 <contact_stiffness>

19.223.3 Description

The smd/hertz style calculates contact forces between SPH particles belonging to different physical bodies.

The contact forces are calculated using a Hertz potential, which evaluates the overlap between two particles (whose spatial extents are defined via its contact radius). The effect is that a particles cannot penetrate into each other. The parameter <contact_stiffness> has units of pressure and should equal roughly one half of the Young’s modulus (or bulk modulus in the case of fluids) of the material model associated with the SPH particles.
The parameter \textit{scale\_factor} can be used to scale the particles’ contact radii. This can be useful to control how close particles can approach each other. Usually, \textit{scale\_factor} = 1.0.

19.223.4 Mixing, shift, table, tail correction, restart, rRESPA info

No mixing is performed automatically. Currently, no part of MACHDYN supports restarting nor minimization. rRESPA does not apply to this pair style.

19.223.5 Restrictions

This fix is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the \textit{Build package} page for more info.

\end{verbatim}

19.224.2 Examples

\begin{verbatim}
pair\_style smd/tlsph
\end{verbatim}

19.224.3 Description

The \textit{smd/tlsph} style computes particle interactions according to continuum mechanics constitutive laws and a Total-Lagrangian Smooth-Particle Hydrodynamics algorithm.

This pair style is invoked with the following command:

\begin{verbatim}
pair\_style smd/tlsph
pair\_coeff i j ^COMMON rho0 E nu Q1 Q2 hg Cp & ^END
\end{verbatim}
Here, \( i \) and \( j \) denote the LAMMPS particle types for which this pair style is defined. Note that \( i \) and \( j \) must be equal, i.e., no tlsph cross interactions between different particle types are allowed. In contrast to the usual LAMMPS pair coeff definitions, which are given solely a number of floats and integers, the tlsph pair coeff definition is organized using keywords. These keywords mark the beginning of different sets of parameters for particle properties, material constitutive models, and damage models. The pair coeff line must be terminated with the *END keyword. The use the line continuation operator & is recommended. A typical invocation of the tlsph for a solid body would consist of an equation of state for computing the pressure (the diagonal components of the stress tensor), and a material model to compute shear stresses (the off-diagonal components of the stress tensor). Damage and failure models can also be added.

Please see the SMD user guide for a complete listing of the possible keywords and material models.

### 19.224.4 Mixing, shift, table, tail correction, restart, rRESPA info

No mixing is performed automatically. Currently, no part of MACHDYN supports restarting nor minimization. rRESPA does not apply to this pair style.

### 19.224.5 Restrictions

This fix is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

### 19.225 pair_style smd/tri_surface command

#### 19.225.1 Syntax

```
pair_style smd/tri_surface scale_factor
```
19.225.2 Examples

```
pair_style smd/tri_surface 1.0
pair_coeff 1 1 <contact_stiffness>
```

19.225.3 Description

The `smd/tri_surface` style calculates contact forces between SPH particles and a rigid wall boundary defined via the `smd/wall_surface` fix.

The contact forces are calculated using a Hertz potential, which evaluates the overlap between a particle (whose spatial extents are defined via its contact radius) and the triangle. The effect is that a particle cannot penetrate into the triangular surface. The parameter `<contact_stiffness>` has units of pressure and should equal roughly one half of the Young’s modulus (or bulk modulus in the case of fluids) of the material model associated with the SPH particle.

The parameter `scale_factor` can be used to scale the particles’ contact radii. This can be useful to control how close particles can approach the triangulated surface. Usually, `scale_factor = 1.0`.

19.225.4 Mixing, shift, table, tail correction, restart, rRESPA info

No mixing is performed automatically. Currently, no part of MACHDYN supports restarting nor minimization. rRESPA does not apply to this pair style.

19.225.5 Restrictions

This fix is part of the MACHDYN package. It is only enabled if LAMMPS was built with that package. See the `Build package` page for more info.

19.225.6 Related commands

`pair_coeff`

19.225.7 Default

```

19.226 `pair_style smd/ulsph` command

19.226.1 Syntax

```
pair_style smd/ulsph args
```

- these keywords must be given

```
keyword = *DENSITY_SUMMATION or *DENSITY_CONTINUITY and *VELOCITY_GRADIENT or *NO_VELOCITY_GRADIENT and *GRADIENT_CORRECTION or *NO_GRADIENT_CORRECTION
```
19.226.2 Examples

<table>
<thead>
<tr>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>pair_style smd/ulsph *DENSITY_CONTINUITY *VELOCITY_GRADIENT *NO_GRADIENT_CORRECTION</td>
</tr>
</tbody>
</table>

19.226.3 Description

The smd/ulsph style computes particle interactions according to continuum mechanics constitutive laws and an updated Lagrangian Smooth-Particle Hydrodynamics algorithm.

This pair style is invoked similar to the following command:

<table>
<thead>
<tr>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>pair_style smd/ulsph *DENSITY_CONTINUITY *VELOCITY_GRADIENT *NO_GRADIENT_CORRECTION</td>
</tr>
<tr>
<td>pair_coeff i j *COMMON rho0 c0 Q1 Cp hg &amp;</td>
</tr>
<tr>
<td>*END</td>
</tr>
</tbody>
</table>

Here, \( i \) and \( j \) denote the LAMMPS particle types for which this pair style is defined. Note that \( i \) and \( j \) can be different, i.e., ulsph cross interactions between different particle types are allowed. However, \( i-i \) respectively \( j-j \) pair_coeff lines have to precede a cross interaction. In contrast to the usual LAMMPS pair coeff definitions, which are given solely a number of floats and integers, the ulsph pair coeff definition is organized using keywords. These keywords mark the beginning of different sets of parameters for particle properties, material constitutive models, and damage models. The pair coeff line must be terminated with the *END keyword. The use the line continuation operator & is recommended.

A typical invocation of the ulsph for a solid body would consist of an equation of state for computing the pressure (the diagonal components of the stress tensor), and a material model to compute shear stresses (the off-diagonal components of the stress tensor).

Note that the use of *GRADIENT_CORRECTION can lead to severe numerical instabilities. For a general fluid simulation, *NO_GRADIENT_CORRECTION is recommended.

Please see the SMD user guide for a complete listing of the possible keywords and material models.

19.226.4 Mixing, shift, table, tail correction, restart, rRESPA info

No mixing is performed automatically. Currently, no part of MACHDYN supports restarting nor minimization. rRESPA does not apply to this pair style.

19.227 pair_style smtbq command

19.227.1 Syntax

\texttt{pair_style smtbq}

19.227.2 Examples

\begin{verbatim}
pair_style smtbq
pair_coeff * * ffield.smtbq.Al2O3 O Al
\end{verbatim}

19.227.3 Description

This pair style computes a variable charge SMTB-Q (Second-Moment tight-Binding QEq) potential as described in \textit{SMTB-Q\textunderscore 1} and \textit{SMTB-Q\textunderscore 2}. Briefly, the energy of metallic-oxygen systems is given by three contributions:

\begin{align*}
E_{\text{tot}} &= E_{\text{ES}} + E_{\text{OO}} + E_{\text{MO}} \\
E_{\text{ES}} &= \sum_i \left[ \lambda_i Q_i + \frac{1}{2} \rho_i Q_i^2 + \frac{1}{2} \sum_{j \neq i} J_{ij}(r_{ij}) f_{\text{cut}}^{R_{\text{coul}}}(r_{ij}) Q_i Q_j \right] \\
E_{\text{OO}} &= \sum_{i,j=O} \left[ C_{\exp}(\frac{r_{ij}}{\rho}) - D f_{\text{cut}}^{R_{\text{OO}}}(r_{ij}) \exp(Br_{ij}) \right] \\
E_{\text{MO}} &= \sum_i E_{\text{cov}}^i + \sum_{j \neq i} A f_{\text{cut}}^{R_{\text{mol}}}(r_{ij}) \exp\left[ -p \left( \frac{r_{ij}}{r_0} - 1 \right) \right]
\end{align*}

where $E_{\text{tot}}$ is the total potential energy of the system, $E_{\text{ES}}$ is the electrostatic part of the total energy, $E_{\text{OO}}$ is the interaction between oxygen atoms and $E_{\text{MO}}$ is a short-range interaction between metal and oxygen atoms. These interactions depend on interatomic distance $r_{ij}$ and/or the charge $Q_i$ of atoms $i$. Cut-off function enables smooth convergence to zero interaction.

The parameters appearing in the upper expressions are set in the \texttt{ffield.SMTBQ.Syst} file where \texttt{Syst} corresponds to the selected system (e.g. \texttt{ffield.SMTBQ.Al2O3}). Examples for TiO\textsubscript{2}, Al\textsubscript{2}O\textsubscript{3} are provided. A single pair\_coeff command is used with the SMTBQ styles which provides the path to the potential file with parameters for needed elements. These are mapped to LAMMPS atom types by specifying additional arguments after the potential filename in the pair\_coeff command. Note that atom type 1 must always correspond to oxygen atoms. As an example, to simulate a TiO\textsubscript{2} system, atom type 1 has to be oxygen and atom type 2 Ti. The following pair\_coeff command should then be used:

\begin{verbatim}
pair_coeff * * PathToLammps/potentials/ffield.smtbq.TiO2 O Ti
\end{verbatim}
The electrostatic part of the energy consists of two components

self-energy of atom \( i \) in the form of a second order charge dependent polynomial and a long-range Coulombic electrostatic interaction. The latter uses the wolf summation method described in *Wolf*, spherically truncated at a longer cutoff, \( R_{\text{coul}} \). The charge of each ion is modeled by an orbital Slater which depends on the principal quantum number \( (n) \) of the outer orbital shared by the ion.

Interaction between oxygen, \( E_{OO} \), consists of two parts, an attractive and a repulsive part. The attractive part is effective only at short range (< \( r_1^O \)). The attractive contribution was optimized to study surfaces reconstruction (e.g. *SMTB-Q_2*) in \( \text{TiO}_2 \) and is not necessary for oxide bulk modeling. The repulsive part is the Pauli interaction between the electron clouds of oxygen. The Pauli repulsion and the coulombic electrostatic interaction have same cut off value. In the ffield.SMTBQ.Syst, the keyword ‘buck’ allows to consider only the repulsive O-O interactions. The keyword ‘buckPlusAttr’ allows to consider the repulsive and the attractive O-O interactions.

The short-range interaction between metal-oxygen, \( E_{MO} \) is based on the second moment approximation of the density of states with a N-body potential for the band energy term, \( E_{\text{cov}} \), and a Born-Mayer type repulsive terms as indicated by the keyword ‘second_moment’ in the ffield.SMTBQ.Syst. The energy band term is given by:

\[
E^{(i=M,O)}_{\text{cov}} = - \left\{ \eta_i (\mu_i \xi^0)^2 \sum_{j=O,M} e^{exp[-2qji(\eta_j \eta_i - \delta Q_i)]} \right\}^{1/2}
\]

where \( \eta_i \) is the stoichiometry of atom \( i \), \( \delta Q_i \) is the charge delocalization of atom \( i \), compared to its formal charge \( Q_i^F \). \( n_0 \), the number of hybridized orbitals, is calculated with to the atomic orbitals shared \( d_i \) and the stoichiometry \( \eta_i \). \( r_{c1} \) and \( r_{c2} \) are the two cutoff radius around the fourth neighbors in the cutoff function.

In the formalism used here, \( \xi^0 \) is the energy parameter. \( \xi^0 \) is in tight-binding approximation the hopping integral between the hybridized orbitals of the cation and the anion. In the literature we find many ways to write the hopping integral depending on whether one takes the point of view of the anion or cation. These are equivalent vision. The correspondence between the two visions is explained in appendix A of the article in the SrTiO3 *SMTB-Q_3* (parameter \( \beta \) shown in this article is in fact the \( \beta_0 \)). To summarize the relationship between the hopping integral \( \xi^O \) and the others, we have in an oxide \( C_n O_m \) the following relationship:

\[
\xi^0 = \frac{E_{\text{cov}}}{m} = \frac{\xi_c}{n} \\
\beta_0 = \frac{\beta_c}{\sqrt{n}} = \xi^0 \frac{\sqrt{m}}{\sqrt{n}} + \frac{\sqrt{n}}{2}
\]

Thus parameter \( \mu \), indicated above, is given by \( \mu = \frac{1}{2}(\sqrt{n} + \sqrt{m}) \)

The potential offers the possibility to consider the polarizability of the electron clouds of oxygen by changing the Slater radius of the charge density around the oxygen atoms through the parameters \( rBB, rB \) and \( rS \) in the ffield.SMTBQ.Syst. This change in radius is performed according to the method developed by E. Maras *SMTB-Q_2*. This method needs to determine the number of nearest neighbors around the oxygen. This calculation is based on first \( (r_{1n}) \) and second \( (r_{2n}) \) distances neighbors.

The SMTB-Q potential is a variable charge potential. The equilibrium charge on each atom is calculated by the electronegativity equalization (QEq) method. See *Rick* for further detail. One can adjust the frequency, the maximum number of iterative loop and the convergence of the equilibrium charge calculation. To obtain the energy conservation in NVE thermodynamic ensemble, we recommend to use a convergence parameter in the interval \( 10^{-5} - 10^{-6} \) eV.

The ffield.SMTBQ.Syst files are provided for few systems. They consist of nine parts and the lines beginning with ‘#’ are comments (note that the number of comment lines matter). The first sections are on the potential parameters and others are on the simulation options and might be modified. Keywords are character type and must be enclosed in quotation marks (‘’).

1) Number of different element in the oxide:
• N_elem= 2 or 3
• Divider line

2) Atomic parameters

For the anion (oxygen)
• Name of element (char) and stoichiometry in oxide
• Formal charge and mass of element
• Principal quantum number of outer orbital n), electronegativity ($\chi_0^i$) and hardness ($J_0^i$)
• Ionic radius parameters : max coordination number (coordBB = 6 by default), bulk coordination number (coordB), surface coordination number (coordS) and rBB, rB and rS the slater radius for each coordination number.
  (note : If you don’t want to change the slater radius, use three identical radius values)
• Number of orbital shared by the element in the oxide ($d_i$)
• Divider line

For each cations (metal):
• Name of element (char) and stoichiometry in oxide
• Formal charge and mass of element
• Number of electron in outer orbital (ne), electronegativity ($\chi_0^i$), hardness ($J_0^i$) and rSlater the slater radius for the cation.
• Number of orbitals shared by the elements in the oxide ($d_i$)
• Divider line

3) Potential parameters:
• Keyword for element1, element2 and interaction potential (‘second_moment’ or ‘buck’ or ‘buckPlusAttr’) between element 1 and 2. If the potential is ‘second_moment’, specify ‘oxide’ or ‘metal’ for metal-oxygen or metal-metal interactions respectively.
• Potential parameter:
  – If type of potential is ‘second_moment’ : A (eV), p, $\zeta_0^i$ (eV) and q, $r_{c1}$ (Å), $r_{c2}$ (Å) and $r_0$ (Å)
  – If type of potential is ‘buck’ : C (eV) and $\rho$ (Å)
  – If type of potential is ‘buckPlusAttr’ : C (eV) and $\rho$ (Å) D (eV), $B$ (Å$^{-1}$), $r_{1OO}^O$ (Å) and $r_{2OO}^O$ (Å)
• Divider line

4) Tables parameters:
• Cutoff radius for the Coulomb interaction ($R_{coul}$)
• Starting radius ($r_{min} = 1,18845$ Å) and increments ($dr = 0.001$ Å) for creating the potential table.
• Divider line

5) Rick model parameter:
• Never : parameter to set the frequency of the charge resolution. The charges are evaluated each Never time steps.
• Max number of iterative loop (loopmax) and convergence criterion (prec) in eV of the charge resolution
• Divider line

6) Coordination parameter:
• First ($r_{1n}$) and second ($r_{2n}$) neighbor distances in angstrom

• Divider line

7) Charge initialization mode:

•Keyword ($QInitMode$) and initial oxygen charge ($Q_{init}$). If keyword = ‘true’, all oxygen charges are initially set equal to $Q_{init}$. The charges on the cations are initially set in order to respect the neutrality of the box. If keyword = ‘false’, all atom charges are initially set equal to 0 if you use the $create\_atoms$ command or the charge specified in the file structure using $read\_data$ command.

• Divider line

8) Mode for the electronegativity equalization (Qeq)

•Keyword ($mode$) followed by:
  – QEqAll (one QEq group) | no parameters
  – QEqAllParallel (several QEq groups) | no parameters
  – Surface | zlim (QEq only for $z>zlim$)

• Parameter if necessary

• Divider line

9) Verbose

• If you want the code to work in verbose mode or not : ‘true’ or ‘false’

• If you want to print or not in the file ‘Energy\_component.txt’ the three main contributions to the energy of the system according to the description presented above : ‘true’ or ‘false’ and $N_{Energy}$. This option writes to the file every $N_{Energy}$ time steps. If the value is ‘false’ then $N_{Energy} = 0$. The file takes into account the possibility to have several QEq groups $g$ then it writes: time step, number of atoms in group $g$, electrostatic part of energy, $E_{ES}$, the interaction between oxygen, $E_{OO}$, and short range metal-oxygen interaction, $E_{MO}$.

• If you want to print to the file ‘Electroneg\_component.txt’ the electronegativity component ($\partial E_{tot}/\partial Q_i$) or not: ‘true’ or ‘false’ and $N_{Electroneg}$. This option writes to the file every $N_{Electroneg}$ time steps. If the value is ‘false’ then $N_{Electroneg} = 0$. The file consist of atom number $i$, atom type (1 for oxygen and # higher than 1 for metal), atom position: $x$, $y$ and $z$, atomic charge of atom $i$, electrostatic part of atom $i$ electronegativity, covalent part of atom $i$ electronegativity, the hopping integral of atom $i$ ($Z_{\beta}^{2}$), and box electronegativity.

**Note:** This last option slows down the calculation dramatically. Use only with a single processor simulation.

---

19.227.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the $pair\_modify$ mix, shift, table, and tail options.

This pair style does not write its information to $binary\_restart\_files$, since it is stored in potential files. Thus, you needs to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the $pair$ keyword of the $run\_style respa$ command. It does not support the $inner$, $middle$, $outer$ keywords.
19.227.5 Restrictions

This pair style is part of the SMTBQ package and is only enabled if LAMMPS is built with that package. See the **Build package** page for more info.

This potential requires using atom type 1 for oxygen and atom type higher than 1 for metal atoms.

This pair style requires the **newton** setting to be “on” for pair interactions.

The SMTB-Q potential files provided with LAMMPS (see the potentials directory) are parameterized for metal **units**.

19.227.6 Citing this work

19.228 pair_style snap command

Accelerator Variants: **snap/kk**

19.228.1 Syntax

```
pair_style snap
```

19.228.2 Examples

```
pair_style snap
pair_coeff * * InP.snapcoeff InP.snapparam In In P P
```

19.228.3 Description

Pair style **snap** defines the spectral neighbor analysis potential (SNAP), a machine-learning interatomic potential (**Thompson**). Like the GAP framework of Bartok et al. (**Bartok2010**), SNAP uses bispectrum components to characterize the local neighborhood of each atom in a very general way. The mathematical definition of the bispectrum calculation and its derivatives w.r.t. atom positions is identical to that used by **compute snap**, which is used to fit SNAP
potentials to *ab initio* energy, force, and stress data. In SNAP, the total energy is decomposed into a sum over atom energies. The energy of atom \(i\) is expressed as a weighted sum over bispectrum components.

\[
E_{SNAP}^i(B_1^i, ..., B_K^i) = \beta_0^{\mu_i} + \sum_{k=1}^{K} \beta_k^{\mu_i} B_k^i
\]

where \(B_k^i\) is the \(k\)-th bispectrum component of atom \(i\), and \(\beta_k^{\mu_i}\) is the corresponding linear coefficient that depends on \(\mu_i\), the SNAP element of atom \(i\). The number of bispectrum components used and their definitions depend on the value of \(twojmax\) and other parameters defined in the SNAP parameter file described below. The bispectrum calculation is described in more detail in *compute sna/atom*.

Note that unlike for other potentials, cutoffs for SNAP potentials are not set in the pair_style or pair_coeff command; they are specified in the SNAP potential files themselves.

Only a single pair_coeff command is used with the *snap* style which specifies a SNAP coefficient file followed by a SNAP parameter file and then \(N\) additional arguments specifying the mapping of SNAP elements to LAMMPS atom types, where \(N\) is the number of LAMMPS atom types:

- SNAP coefficient file
- SNAP parameter file
- \(N\) element names = mapping of SNAP elements to atom types

As an example, if a LAMMPS indium phosphide simulation has 4 atom types, with the first two being indium and the third and fourth being phophorous, the pair_coeff command would look like this:

```
pair_coeff * * snap InP.snapcoeff InP.snapparam In In P P
```

The first 2 arguments must be ** so as to span all LAMMPS atom types. The two filenames are for the coefficient and parameter files, respectively. The two trailing ‘In’ arguments map LAMMPS atom types 1 and 2 to the SNAP ‘In’ element. The two trailing ‘P’ arguments map LAMMPS atom types 3 and 4 to the SNAP ‘P’ element.

If a SNAP mapping value is specified as NULL, the mapping is not performed. This can be used when a *snap* potential is used as part of the *hybrid* pair style. The NULL values are placeholders for atom types that will be used with other potentials.

The name of the SNAP coefficient file usually ends in the “.snapcoeff” extension. It may contain coefficients for many SNAP elements. The only requirement is that each of the unique element names appearing in the LAMMPS pair_coeff command appear exactly once in the SNAP coefficient file. It is okay if the SNAP coefficient file contains additional elements not in the pair_coeff command, except when using *chemflag* (see below). The name of the SNAP parameter file usually ends in the “.snapparam” extension. It contains a small number of parameters that define the overall form of the SNAP potential. See the *pair_coeff* page for alternate ways to specify the path for these files.

SNAP potentials are quite commonly combined with one or more other LAMMPS pair styles using the *hybrid/overlay* pair style. As an example, the SNAP tantalum potential provided in the LAMMPS potentials directory combines the *snap* and *zbl* pair styles. It is invoked by the following commands:

```
variable zblcutinner equal 4
variable zblcutouter equal 4.8
variable zblz equal 73
pair_style hybrid/overlay &
zbl ${zblcutinner} ${zblcutouter} snap
pair_coeff * * zbl 0.0
pair_coeff 1 1 zbl ${zblz}
pair_coeff * * snap Ta06A.snapcoeff Ta06A.snapparam Ta
```

It is convenient to keep these commands in a separate file that can be inserted in any LAMMPS input script using the *include* command.
The top of the SNAP coefficient file can contain any number of blank and comment lines (start with #), but follows a strict format after that. The first non-blank non-comment line must contain two integers:

- nelem = Number of elements
- ncoeff = Number of coefficients

This is followed by one block for each of the nelem elements. The first line of each block contains three entries:

- Element name (text string)
- R = Element radius (distance units)
- w = Element weight (dimensionless)

This line is followed by ncoeff coefficients, one per line.

The SNAP parameter file can contain blank and comment lines (start with #) anywhere. Each non-blank non-comment line must contain one keyword/value pair. The required keywords are rcutfac and twojmax. Optional keywords are rfac0, rmin0, switchflag, bzeroflag, quadraticflag, chemflag, bnormflag, wselfallflag, switchinnerflag, sinner, dinner, chunksize, and parallelthresh.

The default values for these keywords are

- rfac0 = 0.99363
- rmin0 = 0.0
- switchflag = 1
- bzeroflag = 1
- quadraticflag = 0
- chemflag = 0
- bnormflag = 0
- wselfallflag = 0
- switchinnerflag = 0
- chunksize = 32768
- parallelthresh = 8192

For detailed definitions of all of these keywords, see the compute sna/atom doc page.

If quadraticflag is set to 1, then the SNAP energy expression includes additional quadratic terms that have been shown to increase the overall accuracy of the potential without much increase in computational cost (Wood).

$$E_{SNAP}^{i}(B^{i}) = \beta_0^{\mu_i} + \beta^{\mu_i} \cdot B_i + \frac{1}{2} B_i^{T} \cdot \alpha^{\mu_i} \cdot B_i$$

where $B_i$ is the $K$-vector of bispectrum components, $\beta^{\mu_i}$ is the $K$-vector of linear coefficients for element $\mu_i$, and $\alpha^{\mu_i}$ is the symmetric $K$ by $K$ matrix of quadratic coefficients. The SNAP coefficient file should contain $K(K+1)/2$ additional coefficients in each element block, the upper-triangular elements of $\alpha^{\mu_i}$.

If chemflag is set to 1, then the energy expression is written in terms of explicit multi-element bispectrum components indexed on ordered triplets of elements, which has been shown to increase the ability of the SNAP potential to capture energy differences in chemically complex systems, at the expense of a significant increase in computational cost (Cusentino).

$$E_{SNAP}^{i}(B^{i}) = \beta_0^{\mu_i} + \sum_{\kappa,\lambda,\mu} \beta_{\mu_i}^{\kappa,\lambda} \cdot B_i^{\kappa,\lambda}$$
where $B_{\kappa \lambda \mu}^i$ is the $K$-vector of bispectrum components for neighbors of elements $\kappa$, $\lambda$, and $\mu$. The SNAP coefficient file should contain a total of $KN_{\text{elem}}^3$ coefficients in each element block, where $N_{\text{elem}}$ is the number of elements in the SNAP coefficient file, which must equal the number of unique elements appearing in the LAMMPS pair_coeff command, to avoid ambiguity in the number of coefficients.

The keyword `switchinnerflag` activates an additional switching function that smoothly turns off contributions to the SNAP potential from neighbor atoms at short separations. If `switchinnerflag` is set to 1 then the additional keywords `sinner` and `dinner` must also be provided. Each of these is followed by $n_{\text{elements}}$ values, where $n_{\text{elements}}$ is the number of unique elements appearing in appearing in the LAMMPS pair_coeff command. The element order should correspond to the order in which elements first appear in the pair_coeff command reading from left to right.

The keywords `chunksize` and `parallelthresh` are only applicable when using the pair style `snap` with the KOKKOS package on GPUs and are ignored otherwise. The `chunksize` keyword controls the number of atoms in each pass used to compute the bispectrum components and is used to avoid running out of memory. For example if there are 8192 atoms in the simulation and the `chunksize` is set to 4096, the bispectrum calculation will be broken up into two passes (running on a single GPU). The `parallelthresh` keyword controls a crossover threshold for performing extra parallelism. For small systems, exposing additional parallelism can be beneficial when there is not enough work to fully saturate the GPU threads otherwise. However, the extra parallelism also leads to more divergence and can hurt performance when the system is already large enough to saturate the GPU threads. Extra parallelism will be performed if the `chunksize` (or total number of atoms per GPU) is smaller than `parallelthresh`.

**Note:** The previously used `diagonalstyle` keyword was removed in 2019, since all known SNAP potentials use the default value of 3.

---

**19.228.4 Mixing, shift, table, tail correction, restart, rRESPA info**

For atom type pairs $I,J$ and $I \neq J$, where types $I$ and $J$ correspond to two different element types, mixing is performed by LAMMPS with user-specifiable parameters as described above. You never need to specify a pair_coeff command with $I \neq J$ arguments for this style.

This pair style does not support the `pair_modify` shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
19.228.5 Restrictions

This style is part of the ML-SNAP package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

19.228.6 Related commands

compute sna/atom, compute snad/atom, compute snav/atom, compute snap

19.228.7 Default

none

19.229 pair_style soft command

Accelerator Variants: soft/gpu, soft/omp

19.229.1 Syntax

```
pair_style soft cutoff
```

- cutoff = global cutoff for soft interactions (distance units)

19.229.2 Examples

```
pair_style soft 1.0
pair_coeff * * 10.0
pair_coeff 1 1 10.0 3.0

pair_style soft 1.0
pair_coeff * * 0.0
variable prefactor equal ramp(0,30)
fix 1 all adapt 1 pair soft a * * v_prefactor
```
19.229.3 Description

Style soft computes pairwise interactions with the formula

\[ E = A \left[ 1 + \cos \left( \frac{\pi r}{r_c} \right) \right] \quad r < r_c \]

It is useful for pushing apart overlapping atoms, since it does not blow up as \( r \) goes to 0. \( A \) is a prefactor that can be made to vary in time from the start to the end of the run (see discussion below), e.g. to start with a very soft potential and slowly harden the interactions over time. \( r_c \) is the cutoff. See the fix nve/limit command for another way to push apart overlapping atoms.

The following coefficients must be defined for each pair of atom types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, or by mixing as described below:

- \( A \) (energy units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global soft cutoff is used.

Note: The syntax for pair_coeff with a single \( A \) coeff is different in the current version of LAMMPS than in older versions which took two values, \( A_{\text{start}} \) and \( A_{\text{stop}} \), to ramp between them. This functionality is now available in a more general form through the fix adapt command, as explained below. Note that if you use an old input script and specify \( A_{\text{start}} \) and \( A_{\text{stop}} \) without a cutoff, then LAMMPS will interpret that as \( A \) and a cutoff, which is probably not what you want.

The fix adapt command can be used to vary \( A \) for one or more pair types over the course of a simulation, in which case pair_coeff settings for \( A \) must still be specified, but will be overridden. For example these commands will vary the prefactor \( A \) for all pairwise interactions from 0.0 at the beginning to 30.0 at the end of a run:

```
variable prefactor equal ramp(0,30)
fix 1 all adapt 1 pair soft a * * v_prefactor
```

Note that a formula defined by an equal-style variable can use the current timestep, elapsed time in the current run, elapsed time since the beginning of a series of runs, as well as access other variables.

Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
19.229.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I ≠ J, the A coefficient and cutoff distance for this pair style can be mixed. A is always mixed via a geometric rule. The cutoff is mixed according to the pair_modify mix value. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the pair_modify shift option, since the pair interaction goes to 0.0 at the cutoff.

The pair_modify table and tail options are not relevant for this pair style.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

pair_style sph/heatconduction
```

19.230.2 Examples

```
pair_style sph/heatconduction
pair_coeff * * 1.0 2.4
```
19.230.3 Description

The sph/heatconduction style computes heat transport between SPH particles. The transport model is the diffusion equation for the internal energy.

See this PDF guide to using SPH in LAMMPS.

The following coefficients must be defined for each pair of atom types via the pair_coeff command as in the examples above.

- \(D\) diffusion coefficient (length^2/time units)
- \(h\) kernel function cutoff (distance units)

19.230.4 Mixing, shift, table, tail correction, restart, rRESPA info

This style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

This style does not support the pair_modify shift, table, and tail options.

This style does not write information to binary restart files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

19.230.5 Restrictions

19.236 pair_style spin/dipole/cut command

19.237 pair_style spin/dipole/long command

19.237.1 Syntax

\begin{verbatim}
pair_style spin/dipole/cut cutoff
pair_style spin/dipole/long cutoff
\end{verbatim}

• cutoff = global cutoff for magnetic dipole energy and forces (optional) (distance units)

19.237.2 Examples

\begin{verbatim}
pair_style spin/dipole/cut 10.0
pair_coeff * * 10.0
pair_coeff 2 3 8.0

pair_style spin/dipole/long 9.0
pair_coeff * * 10.0
pair_coeff 2 3 6.0
\end{verbatim}

19.237.3 Description

Style spin/dipole/cut computes a short-range dipole-dipole interaction between pairs of magnetic particles that each have a magnetic spin. The magnetic dipole-dipole interactions are computed by the following formulas for the magnetic energy, magnetic precession vector omega and mechanical force between particles I and J.

\begin{align*}
H_{\text{long}} &= -\frac{\mu_0 (\mu_B)^2}{4\pi} \sum_{i,j} \frac{g_i g_j}{r_{ij}^3} \left( 3 (\vec{e}_{ij} \cdot \vec{s}_i) (\vec{e}_{ij} \cdot \vec{s}_j) - \vec{s}_i \cdot \vec{s}_j \right) \\
\omega_i &= \frac{\mu_0 (\mu_B)^2}{4\pi \hbar} \sum_j \frac{g_i g_j}{r_{ij}^4} \left( 3 (\vec{e}_{ij} \cdot \vec{s}_j) \vec{e}_{ij} - \vec{s}_j \right) \\
F_i &= \frac{3 \mu_0 (\mu_B)^2}{4\pi} \sum_j \frac{g_i g_j}{r_{ij}^4} \left[ \left( (\vec{s}_i \cdot \vec{s}_j) - 5(\vec{e}_{ij} \cdot \vec{s}_i)(\vec{e}_{ij} \cdot \vec{s}_j) \right) \vec{e}_{ij} + \left( (\vec{e}_{ij} \cdot \vec{s}_i) \vec{s}_j + (\vec{e}_{ij} \cdot \vec{s}_j) \vec{s}_i \right) \right]
\end{align*}
where \( \vec{s}_i \) and \( \vec{s}_j \) are the spin on two magnetic particles, \( r \) is their separation distance, and the vector \( \vec{e}_{ij} = \frac{r_i - r_j}{|r_i - r_j|} \) is the direction vector between the two particles.

Style spin/dipole/long computes long-range magnetic dipole-dipole interaction. A kspace_style must be defined to use this pair style. Currently, kspace_style ewald/dipole/spin and kspace_style pppm/dipole/spin support long-range magnetic dipole-dipole interactions.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

19.237.4 Restrictions

The spin/dipole/cut and spin/dipole/long styles are part of the SPIN package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

Using dipole/spin pair styles with electron units is not currently supported.

pair_coeff 1 2 dmi 2.6 0.001 1.0 0.0 0.0
pair_coeff 1 2 dmi 4.0 0.00109 0.0 0.0 1.0
```
19.238.3 Description

Style spin/dmi computes the Dzyaloshinskii-Moriya (DM) interaction between pairs of magnetic spins. According to the expression reported in (Rohart), one has the following DM energy:

\[ H_{dm} = \sum_{i,j=1, i \neq j}^{N} \left( \vec{e}_{ij} \times \vec{D} \right) \cdot \left( \vec{s}_i \times \vec{s}_j \right), \]

where \( \vec{s}_i \) and \( \vec{s}_j \) are two neighboring magnetic spins of two particles, \( \vec{e}_{ij} = \frac{r_i - r_j}{|r_i - r_j|} \) is the unit vector between sites \( i \) and \( j \), and \( \vec{D} \) is the DM vector defining the intensity (in eV) and the direction of the interaction.

In (Rohart), \( \vec{D} \) is defined as the direction normal to the film oriented from the high spin-orbit layer to the magnetic ultra-thin film.

The application of a spin-lattice Poisson bracket to this energy (as described in (Tranchida)) allows to derive a magnetic torque \( \omega \) and a mechanical force \( F \) (for spin-lattice calculations only) for each magnetic particle \( i \):

\[ \vec{\omega}_i = -\frac{1}{\hbar} \sum_j^{Neigh} \vec{s}_j \times \left( \vec{e}_{ij} \times \vec{D} \right) \quad \text{and} \quad \vec{F}_i = -\sum_j^{Neigh} \frac{1}{r_{ij}} \vec{D} \times (\vec{s}_i \times \vec{s}_j) \]

More details about the derivation of these torques/forces are reported in (Tranchida).

For the spin/dmi pair style, the following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, and set in the following order:

- \( rc \) (distance units)
- \( |D| \) (energy units)
- \( Dx, Dy, Dz \) (direction of \( D \))

Note that \( rc \) is the radius cutoff of the considered DM interaction, \( |D| \) is the norm of the DM vector (in eV), and \( Dx, Dy \) and \( Dz \) define its direction.

None of those coefficients is optional. If not specified, the spin/dmi pair style cannot be used.

19.238.4 Restrictions

All the pair/spin styles are part of the SPIN package. These styles are only enabled if LAMMPS was built with this package, and if the atom_style "spin" was declared. See the Build package page for more info.

\end{verbatim}

19.240.3 Description

Style \textit{spin/exchange} computes the exchange interaction between pairs of magnetic spins:

\[ H_{ex} = -\sum_{i,j} J_{ij}(r_{ij}) \mathbf{s}_i \cdot \mathbf{s}_j \]

where $\mathbf{s}_i$ and $\mathbf{s}_j$ are two unit vectors representing the magnetic spins of two particles (usually atoms), and $r_{ij} = |\mathbf{r}_i - \mathbf{r}_j|$ is the inter-atomic distance between those two particles. The summation is over pairs of nearest neighbors. $J(r_{ij})$ is a function defining the intensity and the sign of the exchange interaction for different neighboring shells.

Style \textit{spin/exchange/biquadratic} computes a biquadratic exchange interaction between pairs of magnetic spins:

\[ H_{bi} = -\sum_{i,j} J_{ij}(r_{ij}) \mathbf{s}_i \cdot \mathbf{s}_j - \sum_{i,j} K_{ij}(r_{ij}) (\mathbf{s}_i \cdot \mathbf{s}_j)^2 \]

where $\mathbf{s}_i$, $\mathbf{s}_j$, $r_{ij}$ and $J(r_{ij})$ have the same definitions as above, and $K(r_{ij})$ is a second function, defining the intensity and the sign of the biquadratic term.
The interatomic dependence of $J(r_{ij})$ and $K(r_{ij})$ in both interactions above is defined by the following function:

$$f(r_{ij}) = 4a \left( \frac{r_{ij}}{d} \right)^2 \left( 1 - b \left( \frac{r_{ij}}{d} \right)^2 \right) e^{-\left( \frac{r_{ij}}{d} \right)^2} \Theta(R_c - r_{ij})$$

where $a$, $b$, and $d$ are the three constant coefficients defined in the associated “pair_coeff” command, and $R_c$ is the radius cutoff associated to the pair interaction (see below for more explanations).

The coefficients $a$, $b$, and $d$ need to be fitted so that the function above matches with the value of the exchange interaction for the $N$ neighbor shells taken into account. Examples and more explanations about this function and its parameterization are reported in (Tranchida).

When a spin/exchange/biquadratic pair style is defined, six coefficients (three for $J(r_{ij})$, and three for $K(r_{ij})$) have to be fitted.

From this exchange interaction, each spin $i$ will be submitted to a magnetic torque $\vec{\omega}_i$, and its associated atom can be submitted to a force $\vec{F}_i$ for spin-lattice calculations (see fix nve/spin), such as:

$$\vec{\omega}_i = \frac{1}{\hbar} \sum_{j}^{\text{Neigh}} J(r_{ij}) \vec{s}_j \quad \text{and} \quad \vec{F}_i = \sum_{j}^{\text{Neigh}} \frac{\partial J(r_{ij})}{\partial r_{ij}} (\vec{s}_i \cdot \vec{s}_j) \vec{e}_{ij}$$

with $\hbar$ the Planck constant (in metal units), and $\vec{e}_{ij} = \frac{\vec{r}_i - \vec{r}_j}{|\vec{r}_i - \vec{r}_j|}$ the unit vector between sites $i$ and $j$. Equivalent forces and magnetic torques are generated for the biquadratic term when a spin/exchange/biquadratic pair style is defined.

More details about the derivation of these torques/forces are reported in (Tranchida).

For the spin/exchange and spin/exchange/biquadratic pair styles, the following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the examples above, or in the data file or restart files read by the read_data or read_restart commands, and set in the following order:

- $R_c$ (distance units)
- $a$ (energy units)
- $b$ (adim parameter)
- $d$ (distance units)

for the spin/exchange pair style, and:

- $R_c$ (distance units)
- $a_j$ (energy units)
- $b_j$ (adim parameter)
- $d_j$ (distance units)
- $a_k$ (energy units)
- $b_k$ (adim parameter)
- $d_k$ (distance units)

for the spin/exchange/biquadratic pair style.

Note that $R_c$ is the radius cutoff of the considered exchange interaction, and $a$, $b$ and $d$ are the three coefficients performing the parameterization of the function $J(r_{ij})$ defined above (in the biquadratic style, $a_j$, $b_j$, $d_j$ and $a_k$, $b_k$, $d_k$ are the coefficients of $J(r_{ij})$ and $K(r_{ij})$ respectively).

None of those coefficients is optional. If not specified, the spin/exchange pair style cannot be used.

Offsetting magnetic forces and energies:
For spin-lattice simulation, it can be useful to offset the mechanical forces and energies generated by the exchange interaction. The offset keyword allows to apply this offset. By setting offset to yes, the energy definitions above are replaced by:

\[ H_{ex} = - \sum_{i,j} J_{ij} (r_{ij}) \left[ \vec{s}_i \cdot \vec{s}_j - 1 \right] \]

for the spin/exchange pair style, and:

\[ H_{bi} = - \sum_{i,j} J_{ij} (r_{ij}) \left[ \vec{s}_i \cdot \vec{s}_j - 1 \right] - \sum_{i,j} K_{ij} (r_{ij}) \left[ (\vec{s}_i \cdot \vec{s}_j)^2 - 1 \right] \]

for the spin/exchange/biquadratic pair style.

Note that this offset only affects the calculation of the energy and mechanical forces. It does not modify the calculation of the precession vectors (and thus does no impact the purely magnetic properties). This ensures that when all spins are aligned, the magnetic energy and the associated mechanical forces (and thus the pressure generated by the magnetic potential) are null.

Note: This offset term can be very important when calculations such as equations of state (energy vs volume, or energy vs pressure) are being performed. Indeed, setting the offset term ensures that at the ground state of the crystal and at the equilibrium magnetic configuration (typically ferromagnetic), the pressure is null, as expected. Otherwise, magnetic forces could generate a residual pressure.

When the offset option is set to no, no offset is applied (also corresponding to the default option).

19.240.4 Restrictions

All the pair/spin styles are part of the SPIN package. These styles are only enabled if LAMMPS was built with this package, and if the atom_style “spin” was declared. See the Build package page for more info.

```

- cutoff = global cutoff pair (distance in metal units)

19.241.2 Examples

```
pair_style spin/magelec 4.5
pair_coeff *= magelec 4.5 0.00109 1.0 1.0 1.0
```

19.241.3 Description

Style spin/me computes a magneto-electric interaction between pairs of magnetic spins. According to the derivation reported in (Katsura), this interaction is defined as:

\[
\vec{\omega}_i = -\frac{1}{\hbar} \sum_{j}^{\text{Neigh}} \vec{s}_j \times \vec{D}(r_{ij})
\]

\[
\vec{F}_i = -\sum_{j}^{\text{Neigh}} \frac{\partial D(r_{ij})}{\partial r_{ij}} (\vec{s}_i \times \vec{s}_j) \cdot \vec{r}_{ij}
\]

where \(\vec{s}_i\) and \(\vec{s}_j\) are neighboring magnetic spins of two particles.

From this magneto-electric interaction, each spin \(i\) will be submitted to a magnetic torque \(\vec{\omega}\), and its associated atom can be submitted to a force \(\vec{F}\) for spin-lattice calculations (see fix nve/spin), such as:

\[
\vec{F}_i = -\sum_{j}^{\text{Neighbor}} (\vec{s}_i \times \vec{s}_j) \times \vec{E}
\]

\[
\vec{\omega}^i = -\frac{1}{\hbar} \sum_{j}^{\text{Neighbor}} \vec{s}_j \times \left(\vec{E} \times r_{ij}\right)
\]

with \(\hbar\) the Planck constant (in metal units) and \(\vec{E}\) an electric polarization vector. The norm and direction of \(\vec{E}\) are giving the intensity and the direction of a screened dielectric atomic polarization (in eV).

More details about the derivation of these torques/forces are reported in (Tranchida).
19.241.4 Restrictions

All the pair/spin styles are part of the SPIN package. These styles are only enabled if LAMMPS was built with this package, and if the atom_style “spin” was declared. See the Build package page for more info.

19.242 pair_style spin/neel command

19.242.1 Syntax

```
pair_style spin/neel cutoff
```

- cutoff = global cutoff pair (distance in metal units)

19.242.2 Examples

```
pair_style spin/neel 4.0
pair_coeff * * neel 4.0 0.0048 0.234 1.168 2.6905 0.705 0.652
pair_coeff 1 2 neel 4.0 0.0048 0.234 1.168 0.0 0.0 1.0
```

19.242.3 Description

Style spin/neel computes the Neel pair anisotropy model between pairs of magnetic spins:

\[ H_{\text{Neel}} = - \sum_{i,j=1,i\neq j}^{N} g_1(r_{ij}) \left( (e_{ij} \cdot s_i)(e_{ij} \cdot s_j) - \frac{s_i \cdot s_j}{3} \right) + g_1(r_{ij}) \left( (e_{ij} \cdot s_i)^2 - \frac{s_i \cdot s_j}{3} \right) \left( (e_{ij} \cdot s_j)^2 - \frac{s_i \cdot s_j}{3} \right) + g_2(r_{ij}) \left( e_{ij} \cdot s_i \right) \left( e_{ij} \cdot s_j \right) \]

where \( s_i \) and \( s_j \) are two neighboring magnetic spins of two particles, \( r_{ij} = |r_i - r_j| \) is the inter-atomic distance between the two particles, \( e_{ij} = \frac{r_i - r_j}{|r_i - r_j|} \) is their normalized separation vector and \( g_1, g_2 \) are three functions defining the intensity of the dipolar and quadrupolar contributions, with:

\[
g_1(r_{ij}) = g(r_{ij}) + \frac{12}{35} q(r_{ij})
\]
\[
g_1(r_{ij}) = \frac{9}{5} q(r_{ij})
\]
\[
g_2(r_{ij}) = -\frac{2}{5} q(r_{ij})
\]
With the functions $g(r_{ij})$ and $q(r_{ij})$ defined and fitted according to the same Bethe-Slater function used to fit the exchange interaction:

$$J(r_{ij}) = 4a \left( \frac{r_{ij}}{d} \right)^2 \left( 1 - b \left( \frac{r_{ij}}{d} \right)^2 \right) e^{-\left( \frac{r_{ij}}{d} \right)^2} \Theta(R_c - r_{ij})$$

where $a$, $b$, and $d$ are the three constant coefficients defined in the associated “pair_coeff” command.

The coefficients $a$, $b$, and $d$ need to be fitted so that the function above matches with the values of the magneto-elastic constant of the materials at stake.

Examples and more explanations about this function and its parameterization are reported in (Tranchida). More examples of parameterization will be provided in future work.

From this DM interaction, each spin $i$ will be submitted to a magnetic torque $\omega$ and its associated atom to a force $F$ (for spin-lattice calculations only).

More details about the derivation of these torques/forces are reported in (Tranchida).

19.243.3 Description

Style srp computes a soft segmental repulsive potential (SRP) that acts between pairs of bonds. This potential is useful for preventing bonds from passing through one another when a soft non-bonded potential acts between beads, for example, DPD polymer chains. An example input script that uses this command is provided in examples/PACKAGES/srp.

Bonds of specified type btype interact with one another through a bond-pairwise potential, such that the force on bond \( i \) due to bond \( j \) is as follows

\[
F_{\text{SRP}}^{ij} = C \left( 1 - \frac{r}{r_c} \right) \hat{r}_{ij} \quad r < r_c
\]

where \( r \) and \( \hat{r}_{ij} \) are the distance and unit vector between the two bonds. Note that btype can be specified as an asterisk "*", which case the interaction is applied to all bond types. The mid option computes \( r \) and \( \hat{r}_{ij} \) from the midpoint distance between bonds. The min option computes \( r \) and \( \hat{r}_{ij} \) from the minimum distance between bonds. The force acting on a bond is mapped onto the two bond atoms according to the lever rule,

\[
F_{\text{SRP}}^{i1} = F_{\text{SRP}}^{ij} (L)
\]

\[
F_{\text{SRP}}^{i2} = F_{\text{SRP}}^{ij} (1 - L)
\]

where \( L \) is the normalized distance from the atom to the point of closest approach of bond \( i \) and \( j \). The mid option takes \( L \) as 0.5 for each interaction as described in (Sirk).

The following coefficients must be defined via the pair_coeff command as in the examples above, or in the data file or restart file read by the read_data or read_restart commands:

- \( C \) (force units)
- \( r_c \) (distance units)

The last coefficient is optional. If not specified, the global cutoff is used.

**Note:** Pair style srp considers each bond of type btype to be a fictitious “particle” of type bptype, where bptype is either the largest atom type in the system, or the type set by the bptype flag. Any actual existing particles with this atom type will be deleted at the beginning of a run. This means you must specify the number of types in your system accordingly; usually to be one larger than what would normally be the case, e.g. via the create_box or by changing the header in your data file. The fictitious “bond particles” are inserted at the beginning of the run, and serve as placeholders that define the position of the bonds. This allows neighbor lists to be constructed and pairwise interactions to be computed in almost the same way as is done for actual particles. Because bonds interact only with other bonds, pair_style hybrid
should be used to turn off interactions between atom type \textit{bptype} and all other types of atoms. An error will be flagged if \textit{pair_style hybrid} is not used.

The optional \textit{exclude} keyword determines if forces are computed between first neighbor (directly connected) bonds. For a setting of \textit{no}, first neighbor forces are computed; for \textit{yes} they are not computed. A setting of \textit{no} cannot be used with the \textit{min} option for distance calculation because the minimum distance between directly connected bonds is zero.

Pair style \textit{srp} turns off normalization of thermodynamic properties by particle number, as if the command \textit{thermo_modify norm no} had been issued.

The pairwise energy associated with style \textit{srp} is shifted to be zero at the cutoff distance \(r_c\).

19.243.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing.

This pair style does not support the \textit{pair_modify} shift option for the energy of the pair interaction. Note that as discussed above, the energy term is already shifted to be 0.0 at the cutoff distance \(r_c\).

The \textit{pair_modify} table option is not relevant for this pair style.

This pair style does not support the \textit{pair_modify} tail option for adding long-range tail corrections to energy and pressure.

This pair style writes global and per-atom information to \textit{binary restart files}. Pair \textit{srp} should be used with \textit{pair_style hybrid}, thus the \textit{pair_coeff} commands need to be specified in the input script when reading a restart file.

This pair style can only be used via the \textit{pair} keyword of the \textit{run_style respa} command. It does not support the \textit{inner}, \textit{middle}, \textit{outer} keywords.

19.243.5 Restrictions

This pair style is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the Making LAMMPS section for more info.

This pair style must be used with \textit{pair_style hybrid}.

This pair style requires the \textit{newton} command to be \textit{on} for non-bonded interactions.

This pair style is not compatible with \textit{rigid body integrators}

19.245.3 Description

The sw style computes a 3-body *Stillinger-Weber* potential for the energy $E$ of a system of atoms as

\[
E = \sum_i \sum_{j>i} \phi_2(r_{ij}) + \sum_i \sum_{j\neq i} \sum_{k>j} \phi_3(r_{ij}, r_{ik}, \theta_{ijk})
\]

\[
\phi_2(r_{ij}) = A_{ij} \epsilon_{ij} \left[ B_{ij} \left( \frac{\sigma_{ij}}{r_{ij}} \right)^{\rho_{ij}} - \left( \frac{\sigma_{ij}}{r_{ij}} \right)^{\psi_{ij}} \right] \exp \left( \frac{\sigma_{ij}}{r_{ij} - a_{ij} \sigma_{ij}} \right)
\]

\[
\phi_3(r_{ij}, r_{ik}, \theta_{ijk}) = \lambda_{ijk} \epsilon_{ijk} \left[ \cos \theta_{ij,k} - \cos \theta_{0ijk} \right]^2 \exp \left( \frac{\gamma_{ijk} \sigma_{ijk}}{r_{ij} - a_{ijk} \sigma_{ijk}} \right) \exp \left( \frac{\gamma_{ikj} \sigma_{ikj}}{r_{ik} - a_{ikj} \sigma_{ikj}} \right)
\]

19.244. pair_style sw command 2235
where $\phi_2$ is a two-body term and $\phi_3$ is a three-body term. The summations in the formula are over all neighbors $J$ and $K$ of atom $I$ within a cutoff distance $a$.

The *sw/mod* style is designed for simulations of materials when distinguishing three-body angles are necessary, such as borophene and transition metal dichalcogenides, which cannot be described by the original code for the Stillinger-Weber potential. For instance, there are several types of angles around each Mo atom in MoS$_2$, and some unnecessary angle types should be excluded in the three-body interaction. Such exclusion may be realized by selecting proper angle types directly. The exclusion of unnecessary angles is achieved here by the cut-off function ($f_C(\delta)$), which induces only minimum modifications for LAMMPS.

Validation, benchmark tests, and applications of the *sw/mod* style can be found in (Jiang2) and (Jiang3).

The *sw/mod* style computes the energy $E$ of a system of atoms, whose potential function is mostly the same as the Stillinger-Weber potential. The only modification is in the three-body term, where the value of $\delta = \cos \theta_{ijk} - \cos \theta_{0ijk}$ used in the original energy and force expression is scaled by a switching factor $f_C(\delta)$:

$$f_C(\delta) = \begin{cases} 
1 & : |\delta| < \delta_1 \\
\frac{1}{2} + \frac{1}{2} \cos \left(\pi \frac{|\delta| - \delta_1}{\delta_2 - \delta_1}\right) & : \delta_1 < |\delta| < \delta_2 \\
0 & : |\delta| > \delta_2 
\end{cases}$$

This cut-off function decreases smoothly from 1 to 0 over the range $[\delta_1, \delta_2]$. This smoothly turns off the energy and force contributions for $|\delta| > \delta_2$. It is suggested that $\delta_1$ and $\delta_2$ to be the value around 0.5 $|\cos \theta_1 - \cos \theta_2|$, with $\theta_1$ and $\theta_2$ as the different types of angles around an atom. For borophene and transition metal dichalcogenides, $\delta_1 = 0.25$ and $\delta_2 = 0.35$. This value enables the cut-off function to exclude unnecessary angles in the three-body SW terms.

Note: The cut-off function is just to be used as a technique to exclude some unnecessary angles, and it has no physical meaning. It should be noted that the force and potential are inconsistent with each other in the decaying range of the cut-off function, as the angle dependence for the cut-off function is not implemented in the force (first derivation of potential). However, the angle variation is much smaller than the given threshold value for actual simulations, so the inconsistency between potential and force can be neglected in actual simulations.

Only a single pair_coeff command is used with the *sw* and *sw/mod* styles which specifies a Stillinger-Weber potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of SW elements to atom types

See the pair_coeff page for alternate ways to specify the path for the potential file.

As an example, imagine a file SiC.sw has Stillinger-Weber values for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following pair_coeff command:

```
pair_coeff * * SiC.sw Si Si Si C
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the SW file. The final C argument maps LAMMPS atom type 4 to the C element in the SW file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a *sw* potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Stillinger-Weber files in the potentials directory of the LAMMPS distribution have a “.sw” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to the two-body and three-body coefficients in the formula above:

- element 1 (the center atom in a 3-body interaction)
• element 2
• element 3
• $\epsilon$ (energy units)
• $\sigma$ (distance units)
• a
• $\lambda$
• $\gamma$
• $\cos \theta_0$
• A
• B
• p
• q
• tol

The A, B, p, and q parameters are used only for two-body interactions. The $\lambda$ and $\cos \theta_0$ parameters are used only for three-body interactions. The $\epsilon$, $\sigma$, and $a$ parameters are used for both two-body and three-body interactions. $\gamma$ is used only in the three-body interactions, but is defined for pairs of atoms. The non-annotated parameters are unitless.

LAMMPS introduces an additional performance-optimization parameter tol that is used for both two-body and three-body interactions. In the Stillinger-Weber potential, the interaction energies become negligibly small at atomic separations substantially less than the theoretical cutoff distances. LAMMPS therefore defines a virtual cutoff distance based on a user defined tolerance tol. The use of the virtual cutoff distance in constructing atom neighbor lists can significantly reduce the neighbor list sizes and therefore the computational cost. LAMMPS provides a tol value for each of the three-body entries so that they can be separately controlled. If tol = 0.0, then the standard Stillinger-Weber cutoff is used.

The Stillinger-Weber potential file must contain entries for all the elements listed in the pair_coeff command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCSi, SiCC, CSiSi, CSiC, CCSi, CCC), that specify SW parameters for all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.

As annotated above, the first element in the entry is the center atom in a three-body interaction. Thus an entry for SiCC means a Si atom with 2 C atoms as neighbors. The parameter values used for the two-body interaction come from the entry where the second and third elements are the same. Thus the two-body parameters for Si interacting with C, comes from the SiCC entry. The three-body parameters can in principle be specific to the three elements of the configuration. In the literature, however, the three-body parameters are usually defined by simple formulas involving two sets of pairwise parameters, corresponding to the ij and ik pairs, where i is the center atom. The user must ensure that the correct combining rule is used to calculate the values of the three-body parameters for alloys. Note also that the function $\phi_3$ contains two exponential screening factors with parameter values from the ij pair and ik pairs. So $\phi_3$ for a C atom bonded to a Si atom and a second C atom will depend on the three-body parameters for the CSiC entry, and also on the two-body parameters for the CCC and CSiSi entries. Since the order of the two neighbors is arbitrary, the three-body parameters for entries CSiC and CCSi should be the same. Similarly, the two-body parameters for entries SiCC and CSiSi should also be the same. The parameters used only for two-body interactions (A, B, p, and q) in entries whose second and third element are different (e.g. SiCSi) are not used for anything and can be set to 0.0 if desired. This is also true for the parameters in $\phi_{11}$ that are taken from the ij and ik pairs ($\sigma$, $a$, $\gamma$)

19.245. pair_style sw/mod command 2237
Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script. See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

**Note:** When using the INTEL package with this style, there is an additional 5 to 10 percent performance improvement when the Stillinger-Weber parameters `p` and `q` are set to 4 and 0 respectively. These parameters are common for modeling silicon and water.

### 19.245.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I !≠ J, where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

This pair style does not support the `pair_modify shift`, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the `run_style respa` command. It does not support the `inner`, `middle`, `outer` keywords.

### 19.245.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This pair style requires the `newton` setting to be “on” for pair interactions.

The Stillinger-Weber potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the SW potential with any LAMMPS units, but you would need to create your own SW potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

### 19.245.6 Related commands

`pair_coeff`
19.245.7 Default

The default values for the maxdelcs setting of the sw/mod pair style are delta1 = 0.25 and delta2 = 0.35°.

19.246 pair_style sw/angle/table command

19.246.1 Syntax

```
pair_style sw/angle/table
```

- style = sw/angle/table

19.246.2 Examples

```
pair_style sw/angle/table
pair_coeff * * spce.sw type
```

Used in example input script:
```
examples/PACKAGES/manybody_table/in.spce_sw
```

19.246.3 Description

The `sw/angle/table` style is a modification of the original `pair_style sw`. It has been developed for coarse-grained simulations (of water) (Scherer1), but can be employed for all kinds of systems. It computes a modified 3-body Stillinger-Weber potential for the energy E of a system of atoms as

\[
E = \sum_i \sum_{j > i} \phi_2(r_{ij}) + \sum_i \sum_{j \neq i} \sum_{k > j} \phi_3(r_{ij}, r_{ik}, \theta_{ijk})
\]

\[
\phi_2(r_{ij}) = A_{ij} \epsilon_{ij} \left[ B_{ij} \left( \frac{\sigma_{ij}}{r_{ij}} \right)^{q_{ij}} - \left( \frac{\sigma_{ij}}{r_{ij}} \right)^{q_{ij}} \right] \exp \left( \frac{\sigma_{ij}}{r_{ij} - a_{ij}\sigma_{ij}} \right)
\]

\[
\phi_3(r_{ij}, r_{ik}, \theta_{ijk}) = f^3b (\theta_{ijk}) \exp \left( \frac{\gamma_{ij}\sigma_{ij}}{r_{ij} - a_{ij}\sigma_{ij}} \right) \exp \left( \frac{\gamma_{ik}\sigma_{ik}}{r_{ik} - a_{ik}\sigma_{ik}} \right)
\]

where \( \phi_2 \) is a two-body term and \( \phi_3 \) is a three-body term. The summations in the formula are over all neighbors J and K of atom I within a cutoff distance \( a\sigma \). In contrast to the original sw style, sw/angle/table allows for a flexible three-body term \( f^3b (\theta_{ijk}) \) which is read in as a tabulated interaction. It can be parameterized with the csg_fmatch app of VOTCA as available at: https://gitlab.mpcdf.mpg.de/votca/votca.

Only a single pair_coeff command is used with the `sw/angle/table` style which specifies a modified Stillinger-Weber potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N_el additional arguments after the “.sw” filename in the pair_coeff command, where N_el is the number of LAMMPS atom types:
• “.sw” filename
• N_el element names = mapping of SW elements to atom types

See the pair_coeff page for alternate ways to specify the path for the potential file.

As an example, imagine a file SiC.sw has Stillinger-Weber values for Si and C. If your LAMMPS simulation has 4 atom types and you want the first 3 to be Si, and the fourth to be C, you would use the following pair_coeff command:

```
pair_coeff * * SiC.sw Si Si Si C
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1, 2, 3 to the Si element in the SW file. The final C argument maps LAMMPS atom type 4 to the C element in the SW file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a sw/angle/table potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

The (modified) Stillinger-Weber files have a “.sw” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to the two-body and three-body coefficients in the formula above. Here, also the suffix “.sw” is used though the original Stillinger-Weber file format is supplemented with four additional lines per parameter block to specify the tabulated three-body interaction. A single entry then contains:

- element 1 (the center atom in a 3-body interaction)
- element 2
- element 3
- ϵ (energy units)
- σ (distance units)
- a
- λ
- γ
- cosθ₀
- A
- B
- p
- q
- tol
- filename
- keyword
- style
- N

The A, B, p, and q parameters are used only for two-body interactions. The λ and cosθ₀ parameters, only used for three-body interactions in the original Stillinger-Weber style, are read in but ignored in this modified pair style. The ϵ parameter is only used for two-body interactions in this modified pair style and not for the three-body terms. The σ and a parameters are used for both two-body and three-body interactions. γ is used only in the three-body interactions, but is defined for pairs of atoms. The non-annotated parameters are unitless.
LAMMPS introduces an additional performance-optimization parameter tol that is used for both two-body and three-body interactions. In the Stillinger-Weber potential, the interaction energies become negligibly small at atomic separations substantially less than the theoretical cutoff distances. LAMMPS therefore defines a virtual cutoff distance based on a user defined tolerance tol. The use of the virtual cutoff distance in constructing atom neighbor lists can significantly reduce the neighbor list sizes and therefore the computational cost. LAMMPS provides a tol value for each of the three-body entries so that they can be separately controlled. If tol = 0.0, then the standard Stillinger-Weber cutoff is used.

The additional parameters filename, keyword, style, and N refer to the tabulated angular potential \( f^{3b}(\theta_{ijk}) \). The tabulated angular potential has to be of the format as used in the angle_style table command:

An interpolation tables of length \( N \) is created. The interpolation is done in one of 2 styles: linear or spline. For the linear style, the angle is used to find 2 surrounding table values from which an energy or its derivative is computed by linear interpolation. For the spline style, a cubic spline coefficients are computed and stored at each of the \( N \) values in the table. The angle is used to find the appropriate set of coefficients which are used to evaluate a cubic polynomial which computes the energy or derivative.

The filename specifies the file containing the tabulated energy and derivative values of \( f^{3b}(\theta_{ijk}) \). The keyword then specifies a section of the file. The format of this file is as follows (without the parenthesized comments):

```
# Angle potential for harmonic (one or more comment or blank lines)
HAM (keyword is the first text on line)
N 181 FP 0 0 EQ 90.0 (N, FP, EQ parameters)
  (blank line)
1 0.0 200.5 2.5 (index, angle, energy, derivative)
2 1.0 198.0 2.5
... 181 180.0 0.0 0.0
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the \( N \) specified in the Stillinger-Weber potential file. Let \( N_{sw} = N \) in the “.sw” file, and \( N_{file} = “N” \) in the tabulated angular file. What LAMMPS does is a preliminary interpolation by creating splines using the \( N_{file} \) tabulated values as nodal points. It uses these to interpolate as needed to generate energy and derivative values at \( N_{table} \) different points. The resulting tables of length \( N_{sw} \) are then used as described above, when computing energy and force for individual angles and their atoms. This means that if you want the interpolation tables of length \( N_{sw} \) to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set \( N_{sw} = N_{file} \).

The “FP” parameter is optional. If used, it is followed by two values fplo and fphi, which are the second derivatives at the innermost and outermost angle settings. These values are needed by the spline construction routines. If not specified by the “FP” parameter, they are estimated (less accurately) by the first two and last two derivative values in the table.

The “EQ” parameter is also optional. If used, it is followed by a the equilibrium angle value, which is used, for example, by the fix shake command. If not used, the equilibrium angle is set to 180.0.

Following a blank line, the next N lines of the angular table file list the tabulated values. On each line, the first value is the index from 1 to N, the second value is the angle value (in degrees), the third value is the energy (in energy units), and the fourth is \(-dE/d(\theta)\) (also in energy units). The third term is the energy of the 3-atom configuration for the specified angle. The last term is the derivative of the energy with respect to the angle (in degrees, not radians). Thus the units of the last term are still energy, not force. The angle values must increase from one line to the next. The angle values must also begin with 0.0 and end with 180.0, i.e. span the full range of possible angles.
Note that one angular potential file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword of appropriate section of the ".sw" file.

The Stillinger-Weber potential file must contain entries for all the elements listed in the pair_coeff command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCSi, SiCC, CSiSi, CSiC, CCSi, CCC), that specify SW parameters for all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.

As annotated above, the first element in the entry is the center atom in a three-body interaction. Thus an entry for SiCC means a Si atom with 2 C atoms as neighbors. The parameter values used for the two-body interaction come from the entry where the second and third elements are the same. Thus the two-body parameters for Si interacting with C, comes from the SiCC entry. The three-body angular potential \( f_{3b}(\theta_{ijk}) \) can in principle be specific to the three elements of the configuration. However, the user must ensure that it makes physically sense. Note also that the function \( \phi_3 \) contains two exponential screening factors with parameter values from the ij pair and ik pairs. So \( \phi_3 \) for a C atom bonded to a Si atom and a second C atom will depend on the three-body parameters for the CSiC entry, and also on the two-body parameters for the CCC and CSiSi entries. Since the order of the two neighbors is arbitrary, the three-body parameters and the tabulated angular potential for entries CSiC and CCSI should be the same. Similarly, the two-body parameters for entries SiCC and CSI Si should also be the same. The parameters used only for two-body interactions (A, B, p, and q) in entries whose second and third element are different (e.g. SiCSi) are not used for anything and can be set to 0.0 if desired. This is also true for the parameters in \( \phi_3 \) that are taken from the ij and ik pairs (\( \sigma, a, \gamma \)).

Additional input files and reference data can be found at: https://gitlab.mpcdf.mpg.de/votca/votca/-/tree/master/csg-tutorials/spce/3body_sw

19.246.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I != J, where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file, but not for the tabulated angular potential file.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

19.246.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This pair style requires the newton setting to be “on” for pair interactions.
19.246.6 Related commands

pair_coeff * 3 morse.table ENTRY1 7.0
```

19.247.3 Description

Style table creates interpolation tables from potential energy and force values listed in a file(s) as a function of distance. When performing dynamics or minimization, the interpolation tables are used to evaluate energy and forces for pairwise interactions between particles, similar to how analytic formulas are used for other pair styles.

The interpolation tables are created as a pre-computation by fitting cubic splines to the file values and interpolating energy and force values at each of N distances. During a simulation, the tables are used to interpolate energy and force values as needed for each pair of particles separated by a distance R. The interpolation is done in one of 4 styles: lookup, linear, spline, or bitmap.

For the lookup style, the distance R is used to find the nearest table entry, which is the energy or force.

For the linear style, the distance R is used to find the 2 surrounding table values from which an energy or force is computed by linear interpolation.

For the spline style, cubic spline coefficients are computed and stored for each of the N values in the table, one set of splines for energy, another for force. Note that these splines are different than the ones used to pre-compute the N...
values. Those splines were fit to the Nfile values in the tabulated file, where often Nfile < N. The distance R is used to find the appropriate set of spline coefficients which are used to evaluate a cubic polynomial which computes the energy or force.

For the bitmap style, the specified N is used to create interpolation tables that are 2^N in length. The distance R is used to index into the table via a fast bit-mapping technique due to (Wolff), and a linear interpolation is performed between adjacent table values.

The following coefficients must be defined for each pair of atom types via the pair_coeff command as in the examples above.

- filename
- keyword
- cutoff (distance units)

The filename specifies a file containing tabulated energy and force values. The keyword specifies a section of the file. The cutoff is an optional coefficient. If not specified, the outer cutoff in the table itself (see below) will be used to build an interpolation table that extend to the largest tabulated distance. If specified, only file values up to the cutoff are used to create the interpolation table. The format of this file is described below.

If your tabulated potential(s) are designed to be used as the short-range part of one of the long-range solvers specified by the kspace_style command, then you must use one or more of the optional keywords listed above for the pair_style command. These are ewald or pppm or msm or dispersion or tip4p. This is so LAMMPS can insure the short-range potential and long-range solver are compatible with each other, as it does for other short-range pair styles, such as pair_style lj/cut/coul/long. Note that it is up to you to insure the tabulated values for each pair of atom types has the correct functional form to be compatible with the matching long-range solver.

Here are some guidelines for using the pair_style table command to best effect:

- Vary the number of table points; you may need to use more than you think to get good resolution.
- Always use the pair_write command to produce a plot of what the final interpolated potential looks like. This can show up interpolation “features” you may not like.
- Start with the linear style; it’s the style least likely to have problems.
- Use N in the pair_style command equal to the “N” in the tabulation file, and use the “RSQ” or “BITMAP” parameter, so additional interpolation is not needed. See discussion below.
- Make sure that your tabulated forces and tabulated energies are consistent (dE/dr = -F) over the entire range of r values. LAMMPS will warn if this is not the case.
- Use as large an inner cutoff as possible. This avoids fitting splines to very steep parts of the potential.

The format of a tabulated file has an (optional) header followed by a series of one or more sections, defined as follows (without the parenthesized comments). The header must start with a # character and the DATE: and UNITS: tags will be parsed and used:

```
# DATE: 2020-06-10  UNITS: real  CONTRIBUTOR: ... (header line)
# Morse potential for Fe  (one or more comment or blank lines)
MORSE_FE (keyword is first text on line)
N 500 R 1.0 10.0 (N, R, RSQ, BITMAP, FPRIME parameters)
(blank)
1 1.0 25.5 102.34 (index, r, energy, force)
```

(continues on next page)
A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the pair_coeff command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the N specified in the pair_style command. Let Ntable = N in the pair_style command, and Nfile = “N” in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the Nfile tabulated values as nodal points. It uses these to interpolate energy and force values at Ntable different points. The resulting tables of length Ntable are then used as described above, when computing energy and force for individual pair distances. This means that if you want the interpolation tables of length Ntable to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set Ntable = Nfile, and use the “RSQ” or “BITMAP” parameter. This is because the internal table abscissa is always RSQ (separation distance squared), for efficient lookup.

All other parameters are optional. If “R” or “RSQ” or “BITMAP” does not appear, then the distances in each line of the table are used as-is to perform spline interpolation. In this case, the table values can be spaced in r uniformly or however you wish to position table values in regions of large gradients.

If used, the parameters “R” or “RSQ” are followed by 2 values rlo and rhi. If specified, the distance associated with each energy and force value is computed from these 2 values (at high accuracy), rather than using the (low-accuracy) value listed in each line of the table. The distance values in the table file are ignored in this case. For “R”, distances uniformly spaced between rlo and rhi are computed; for “RSQ”, squared distances uniformly spaced between rlo*rlo and rhi*rhi are computed.

Note: If you use “R” or “RSQ”, the tabulated distance values in the file are effectively ignored, and replaced by new values as described in the previous paragraph. If the distance value in the table is not very close to the new value (i.e. round-off difference), then you will be assigning energy/force values to a different distance, which is probably not what you want. LAMMPS will warn if this is occurring.

If used, the parameter “BITMAP” is also followed by 2 values rlo and rhi. These values, along with the “N” value determine the ordering of the N lines that follow and what distance is associated with each. This ordering is complex, so it is not documented here, since this file is typically produced by the pair_write command with its bitmap option. When the table is in BITMAP format, the “N” parameter in the file must be equal to 2^M where M is the value specified in the pair_style command. Also, a cutoff parameter cannot be used as an optional third argument in the pair_coeff command; the entire table extent as specified in the file must be used.

If used, the parameter “FPRIME” is followed by 2 values fplo and fphi which are the derivative of the force at the innermost and outermost distances listed in the table. These values are needed by the spline construction routines. If not specified by the “FPRIME” parameter, they are estimated (less accurately) by the first 2 and last 2 force values in the table. This parameter is not used by BITMAP tables.

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is r (in distance units), the third value is the energy (in energy units), and the fourth is the force (in force units). The r values must increase from one line to the next (unless the BITMAP parameter is specified).

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.
Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Accelerator packages} page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \texttt{-suffix} command-line switch when you invoke LAMMPS, or you can use the \texttt{suffix} command in your input script.

See the \textit{Accelerator packages} page for more instructions on how to use the accelerated styles effectively.

\section*{19.247.4 Mixing, shift, table, tail correction, restart, rRESPA info}

This pair style does not support mixing. Thus, coefficients for all I,J pairs must be specified explicitly.

The \texttt{pair_modify} shift, table, and tail options are not relevant for this pair style.

This pair style writes the settings for the “pair_style table” command to binary restart files, so a pair_style command does not need to specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, \texttt{pair_coeff} commands do need to be specified in the restart input script.

This pair style can only be used via the \texttt{pair} keyword of the \texttt{run_style respa} command. It does not support the \texttt{inner}, \texttt{middle}, \texttt{outer} keywords.

19.248 pair_style table/rx command

Accelerator Variants: table/rx/kk

19.248.1 Syntax

```
pair_style table style N ...
```

- style = lookup or linear or spline or bitmap = method of interpolation
- N = use N values in lookup, linear, spline tables
- weighting = fractional or molecular (optional)

19.248.2 Examples

```
pair_style table/rx linear 1000
pair_style table/rx linear 1000 fractional
pair_style table/rx linear 1000 molecular
pair_coeff * * rxn.table ENTRY1 h2o h2o 10.0
pair_coeff * * rxn.table ENTRY1 1fluid 1fluid 10.0
pair_coeff * 3 rxn.table ENTRY1 h2o no2 10.0
```

19.248.3 Description

Style `table/rx` is used in reaction DPD simulations, where the coarse-grained (CG) particles are composed of m species whose reaction rate kinetics are determined from a set of n reaction rate equations through the `fix rx` command. The species of one CG particle can interact with a species in a neighboring CG particle through a site-site interaction potential model. Style `table/rx` creates interpolation tables of length N from pair potential and force values listed in a file(s) as a function of distance. The files are read by the `pair_coeff` command.

The interpolation tables are created by fitting cubic splines to the file values and interpolating energy and force values at each of N distances. During a simulation, these tables are used to interpolate energy and force values as needed. The interpolation is done in one of 4 styles: `lookup`, `linear`, `spline`, or `bitmap`.

For the `lookup` style, the distance between 2 atoms is used to find the nearest table entry, which is the energy or force.

For the `linear` style, the pair distance is used to find 2 surrounding table values from which an energy or force is computed by linear interpolation.

For the `spline` style, a cubic spline coefficients are computed and stored at each of the N values in the table. The pair distance is used to find the appropriate set of coefficients which are used to evaluate a cubic polynomial which computes the energy or force.

For the `bitmap` style, the N means to create interpolation tables that are 2\(^N\) in length. The pair distance is used to index into the table via a fast bit-mapping technique (Wolff) and a linear interpolation is performed between adjacent table values.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above.

- filename
- keyword
• species1
• species2
• cutoff (distance units)

The filename specifies a file containing tabulated energy and force values. The keyword specifies a section of the file. The cutoff is an optional coefficient. If not specified, the outer cutoff in the table itself (see below) will be used to build an interpolation table that extend to the largest tabulated distance. If specified, only file values up to the cutoff are used to create the interpolation table. The format of this file is described below.

The species tags define the site-site interaction potential between two species contained within two different particles. The species tags must either correspond to the species defined in the reaction kinetics files specified with the fix rx command or they must correspond to the tag “1fluid”, signifying interaction with a product species mixture determined through a one-fluid approximation. The interaction potential is weighted by the geometric average of either the mole fraction concentrations or the number of molecules associated with the interacting coarse-grained particles (see the fractional or molecular weighting pair style options). The coarse-grained potential is stored before and after the reaction kinetics solver is applied, where the difference is defined to be the internal chemical energy (uChem).

Here are some guidelines for using the pair_style table/rx command to best effect:

• Vary the number of table points; you may need to use more than you think to get good resolution.
• Always use the pair_write command to produce a plot of what the final interpolated potential looks like. This can show up interpolation “features” you may not like.
• Start with the linear style; it’s the style least likely to have problems.
• Use N in the pair_style command equal to the “N” in the tabulation file, and use the “RSQ” or “BITMAP” parameter, so additional interpolation is not needed. See discussion below.
• Make sure that your tabulated forces and tabulated energies are consistent (dE/dr = -F) along the entire range of r values.
• Use as large an inner cutoff as possible. This avoids fitting splines to very steep parts of the potential.

The format of a tabulated file is a series of one or more sections, defined as follows (without the parenthesized comments):

```
# Morse potential for Fe  (one or more comment or blank lines)
MORSE_FE  (keyword is first text on line)
N 500 R 1.0 10.0  (N, R, RSQ, BITMAP, FPRIME parameters)
     (blank)
1 1.0 25.5 102.34  (index, r, energy, force)
2 1.02 23.4 98.5
...  
500 10.0 0.001 0.003
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the pair_coeff command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the N specified in the pair_style table/rx command. Let Ntable = N in the pair_style command, and Nfile = “N”...
in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the Nfile tabulated values as nodal points. It uses these to interpolate as needed to generate energy and force values at Ntable different points. The resulting tables of length Ntable are then used as described above, when computing energy and force for individual pair distances. This means that if you want the interpolation tables of length Ntable to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set Ntable = Nfile, and use the “RSQ” or “BITMAP” parameter. The internal table abscissa is RSQ (separation distance squared).

All other parameters are optional. If “R” or “RSQ” or “BITMAP” does not appear, then the distances in each line of the table are used as-is to perform spline interpolation. In this case, the table values can be spaced in r uniformly or however you wish to position table values in regions of large gradients.

If used, the parameters “R” or “RSQ” are followed by 2 values rlo and rhi. If specified, the distance associated with each energy and force value is computed from these 2 values (at high accuracy), rather than using the (low-accuracy) value listed in each line of the table. The distance values in the table file are ignored in this case. For “R”, distances uniformly spaced between rlo and rhi are computed; for “RSQ”, squared distances uniformly spaced between rlo*rlo and rhi*rhi are computed.

If used, the parameter “BITMAP” is also followed by 2 values rlo and rhi. These values, along with the “N” value determine the ordering of the N lines that follow and what distance is associated with each. This ordering is complex, so it is not documented here, since this file is typically produced by the pair_write command with its bitmap option. When the table is in BITMAP format, the “N” parameter in the file must be equal to 2^M where M is the value specified in the pair_style command. Also, a cutoff parameter cannot be used as an optional third argument in the pair_coeff command; the entire table extent as specified in the file must be used.

If used, the parameter “FPRIME” is followed by 2 values fplo and fphi which are the derivative of the force at the innermost and outermost distances listed in the table. These values are needed by the spline construction routines. If not specified by the “FPRIME” parameter, they are estimated (less accurately) by the first 2 and last 2 force values in the table. This parameter is not used by BITMAP tables.

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is r (in distance units), the third value is the energy (in energy units), and the fourth is the force (in force units). The r values must increase from one line to the next (unless the BITMAP parameter is specified).

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

19.248.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly.

The pair_modify shift, table, and tail options are not relevant for this pair style.

This pair style writes the settings for the “pair_style table/rx” command to binary restart files, so a pair_style command does not need to be specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, pair_coeff commands do need to be specified in the restart input script.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.
These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

19.248.5 Restrictions

This command is part of the DPD-REACT package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

pair_coeff * * Si.tersoff Si
```

19.250.3 Description

The `tersoff` style computes a 3-body Tersoff potential (Tersoff 1) for the energy $E$ of a system of atoms as

$$ E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij} $$

$$ V_{ij} = f_C(r_{ij} + \delta) \left[ f_R(r_{ij} + \delta) + b_{ij} f_A(r_{ij} + \delta) \right] $$

$$ f_C(r) = \begin{cases} 
  \frac{1}{2} & r < R - D \\
  \frac{1}{2} - \frac{1}{2} \sin \left( \frac{\pi r}{2R - D} \right) & R - D < r < R + D \\
  0 & r > R + D 
\end{cases} $$

$$ f_R(r) = A \exp(-\lambda_1 r) $$

$$ f_A(r) = -B \exp(-\lambda_2 r) $$

$$ b_{ij} = (1 + \beta^{n} \zeta_{ij}^{n})^{-\frac{1}{2n}} $$

$$ \zeta_{ij} = \sum_{k \neq i,j} f_C(r_{ik} + \delta) g(\theta_{ijk}(r_{ij}, r_{ik})) \exp[\lambda_3 m (r_{ij} - r_{ik})^m] $$

$$ g(\theta) = \gamma_{ijk} \left( 1 + \frac{c^2}{d^2} \right)^{-\frac{c^2}{[d^2 + (\cos \theta - \cos \theta_0)^2]}^{\frac{1}{2}}} $$

where $f_R$ is a two-body term and $f_A$ includes three-body interactions. The summations in the formula are over all neighbors J and K of atom I within a cutoff distance = $R + D$. $\delta$ is an optional negative shift of the equilibrium bond length, as described below.

The `tersoff/table` style uses tabulated forms for the two-body, environment and angular functions. Linear interpolation is performed between adjacent table entries. The table length is chosen to be accurate within $10^{-6}$ with respect to the `tersoff` style energy. The `tersoff/table` should give better performance in terms of speed.

Only a single `pair_coeff` command is used with the `tersoff` style which specifies a Tersoff potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the `pair_coeff` command, where N is the number of LAMMPS atom types:

- `filename`
- N element names = mapping of Tersoff elements to atom types

See the `pair_coeff` page for alternate ways to specify the path for the potential file.

As an example, imagine the SiC.tersoff file has Tersoff values for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following `pair_coeff` command:

```plaintext
pair_coeff * * SiC.tersoff Si Si Si C
```
The first 2 arguments must be ** so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the Tersoff file. The final C argument maps LAMMPS atom type 4 to the C element in the Tersoff file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a tersoff potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Tersoff files in the potentials directory of the LAMMPS distribution have a “.tersoff” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to coefficients in the formula above:

- element 1 (the center atom in a 3-body interaction)
- element 2 (the atom bonded to the center atom)
- element 3 (the atom influencing the 1-2 bond in a bond-order sense)
- \( m \)
- \( \gamma \)
- \( \lambda_3 \) (1/distance units)
- \( c \)
- \( d \)
- \( \cos \theta_0 \) (can be a value < -1 or > 1)
- \( n \)
- \( \beta \)
- \( \lambda_2 \) (1/distance units)
- \( B \) (energy units)
- \( R \) (distance units)
- \( D \) (distance units)
- \( \lambda_1 \) (1/distance units)
- \( A \) (energy units)

The \( n, \beta, \lambda_2, B, \lambda_1, \) and \( A \) parameters are only used for two-body interactions. The \( m, \gamma, \lambda_3, c, d, \) and \( \cos \theta_0 \) parameters are only used for three-body interactions. The \( R \) and \( D \) parameters are used for both two-body and three-body interactions. The non-annotated parameters are unitless. The value of \( m \) must be 3 or 1.

The Tersoff potential file must contain entries for all the elements listed in the pair_coeff command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCSi, SiCC, CSiSi, CSiC, CCSi, CCC), that specify Tersoff parameters for all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.

As annotated above, the first element in the entry is the center atom in a three-body interaction and it is bonded to the second atom and the bond is influenced by the third atom. Thus an entry for SiCC means Si bonded to a C with another C atom influencing the bond. Thus three-body parameters for SiCSi and SiSiC entries will not, in general, be the same. The parameters used for the two-body interaction come from the entry where the second element is repeated. Thus the two-body parameters for Si interacting with C, comes from the SiCC entry.

The parameters used for a particular three-body interaction come from the entry with the corresponding three elements. The parameters used only for two-body interactions \((n, \beta, \lambda_2, B, \lambda_1, \) and \( A \)) in entries whose second and third element are different (e.g. SiCSi) are not used for anything and can be set to 0.0 if desired.
Note that the twobody parameters in entries such as SiCC and CSiSi are often the same, due to the common use of symmetric mixing rules, but this is not always the case. For example, the beta and n parameters in Tersoff_2 (Tersoff_2) are not symmetric. Similarly, the threebody parameters in entries such as SiCSi and SiSiC are often the same, but this is not always the case, particularly the value of R, which is sometimes typed on the first and second elements, sometimes on the first and third elements. Hence the need to specify R and D explicitly for all element triples. For example, while Tersoff’s notation in Tersoff_2 (Tersoff_2) is ambiguous on this point, and properties of the zincblende lattice are the same for either choice, Tersoff’s results for rocksalt are consistent with typing on the first and third elements. Albe et al. adopts the same convention. Conversely, the potential for B/N/C from the Cagin group uses the opposite convention, typing on the first and second elements.

We chose the above form so as to enable users to define all commonly used variants of the Tersoff potential. In particular, our form reduces to the original Tersoff form when m = 3 and gamma = 1, while it reduces to the form of Albe et al. when beta = 1 and m = 1. Note that in the current Tersoff implementation in LAMMPS, m must be specified as either 3 or 1. Tersoff used a slightly different but equivalent form for alloys, which we will refer to as Tersoff_2 potential (Tersoff_2). The tersoff/table style implements Tersoff_2 parameterization only.

LAMMPS parameter values for Tersoff_2 can be obtained as follows: $\gamma_{ijk} = \omega_{ik}$, $\lambda_3 = 0$ and the value of $m$ has no effect. The parameters for species $i$ and $j$ can be calculated using the Tersoff_2 mixing rules:

$$
\lambda_{1}^{ij} = \frac{1}{2}(\lambda_{1}^{i} + \lambda_{1}^{j})
$$

$$
\lambda_{2}^{ij} = \frac{1}{2}(\lambda_{2}^{i} + \lambda_{2}^{j})
$$

$$
A_{i,j} = (A_{i}A_{j})^{1/2}
$$

$$
B_{i,j} = x_{ij}(B_{i}B_{j})^{1/2}
$$

$$
R_{i,j} = (R_{i}R_{j})^{1/2}
$$

$$
S_{i,j} = (S_{i}S_{j})^{1/2}
$$

Tersoff_2 parameters R and S must be converted to the LAMMPS parameters R and D (R is different in both forms), using the following relations: $R=(R’+S’)/2$ and $D=(S’-R’)/2$, where the primes indicate the Tersoff_2 parameters.

In the potentials directory, the file SiCGe.tersoff provides the LAMMPS parameters for Tersoff’s various versions of Si, as well as his alloy parameters for Si, C, and Ge. This file can be used for pure Si, (three different versions), pure C, pure Ge, binary SiC, and binary SiGe. LAMMPS will generate an error if this file is used with any combination involving C and Ge, since there are no entries for the GeC interactions (Tersoff did not publish parameters for this cross-interaction.) Tersoff files are also provided for the SiC alloy (SiC.tersoff) and the GaN (GaN.tersoff) alloys.

Many thanks to Rutuparna Narulkar, David Farrell, and Xiaowang Zhou for helping clarify how Tersoff parameters for alloys have been defined in various papers.

The shift keyword computes the energy $E$ of a system of atoms, whose formula is the same as the Tersoff potential. The only modification is that the original equilibrium bond length ($r_0$) of the system is shifted to $r_0 - \delta$. The minus sign arises because each radial distance $r$ is replaced by $r + \delta$.

The shift keyword is designed for simulations of closely matched van der Waals heterostructures. For instance, consider the case of a system with few-layers graphene atop a thick hexagonal boron nitride (h-BN) substrate simulated using periodic boundary conditions. The experimental lattice mismatch of ~1.8% between graphene and h-BN is not well captured by the equilibrium lattice constants of available potentials, thus a small in-plane strain will be introduced in the system when building a periodic supercell. To minimize the effect of strain on simulation results, the shift keyword allows adjusting the equilibrium bond length of one of the two materials (e.g., h-BN). Validation, benchmark tests, and applications of the shift keyword can be found in (Mandelli_1) and (Ouyang_1).

For the specific case discussed above, the force field can be defined as

```
pair_style  hybrid/overlay rebo tersoff shift -0.00407 ilp/graphene/hbn 16.0 coul/shield,
           -16.0
pair_coeff  *  * rebo CH.rebo NULL NULL C
```

(continues on next page)
LAMMPS Documentation, Release patch 23Jun2022

(continued from previous page)

| pair_coeff | * * tersoff | BNC.tersoff B N NULL |
| pair_coeff | * * ilp/graphene/hbn | BNCH.ILP B N C |
| pair_coeff | 1 1 coul/shield 0.70 |
| pair_coeff | 1 2 coul/shield 0.695 |
| pair_coeff | 2 2 coul/shield 0.69 |

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

19.250.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

19.250.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This pair style requires the newton setting to be “on” for pair interactions.

The shift keyword is not supported by the tersoff/gpu, tersoff/intel, tersoff/kk, tersoff/table or tersoff/table/omp variants.

The tersoff/intel pair style is only available when compiling LAMMPS with the Intel compilers.

The Tersoff potential files provided with LAMMPS (see the potentials directory) are parameterized for “metal” units. In addition the pair style supports converting potential parameters on-the-fly between “metal” and “real” units. You can use the tersoff pair style variants with any LAMMPS units setting, but you would need to create your own Tersoff potential file with coefficients listed in the appropriate units if your simulation does not use “metal” or “real” units.

pair_style tersoff/mod/c
pair_coeff * * Si.tersoff.modc Si Si
```
19.252.3 Description

The tersoff/mod and tersoff/mod/c styles compute a bond-order type interatomic potential (Kumagai) based on a 3-body Tersoff potential (Tersoff_1), (Tersoff_2) with modified cutoff function and angular-dependent term, giving the energy $E$ of a system of atoms as

$$E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij}$$

$$V_{ij} = f_C(r_{ij} + \delta) \left[ f_R(r_{ij} + \delta) + b_{ij} f_A(r_{ij} + \delta) \right]$$

$$f_C(r) = \begin{cases} 
\frac{1}{2} - \frac{9}{16} \sin \left( \frac{\pi}{2} \frac{r - R}{D} \right) - \frac{1}{16} \sin \left( \frac{3\pi}{2} \frac{r - R}{D} \right) : & r < R - D \\
0 : & r > R + D
\end{cases}$$

$$f_R(r) = A \exp(-\lambda_1 r)$$

$$f_A(r) = -B \exp(-\lambda_2 r)$$

$$b_{ij} = (1 + \zeta_{ij})^{-\frac{3}{\pi}}$$

$$\zeta_{ij} = \sum_{k \neq i,j} f_C(r_{ik} + \delta) g(\theta_{ijk}) \exp \left[ \alpha(r_{ij} - r_{ik})^2 \right]$$

$$g(\theta) = c_1 + g_o(\theta) g_a(\theta)$$

$$g_o(\theta) = c_2 \frac{(h - \cos \theta)^2}{c_3 + (h - \cos \theta)^2}$$

$$g_a(\theta) = 1 + c_4 \exp \left[ -c_5 (h - \cos \theta)^2 \right]$$

where $f_R$ is a two-body term and $f_A$ includes three-body interactions. $\delta$ is an optional negative shift of the equilibrium bond length, as described below.

The summations in the formula are over all neighbors $J$ and $K$ of atom $I$ within a cutoff distance $= R + D$. The tersoff/mod/c style differs from tersoff/mod only in the formulation of the $V_{ij}$ term, where it contains an additional $c_0$ term.

$$V_{ij} = f_C(r_{ij} + \delta) \left[ f_R(r_{ij} + \delta) + b_{ij} f_A(r_{ij} + \delta) + c_0 \right]$$

The modified cutoff function $f_C$ proposed by (Murty) and having a continuous second-order differential is employed. The angular-dependent term $g(\theta)$ was modified to increase the flexibility of the potential.

The tersoff/mod potential is fitted to both the elastic constants and melting point by employing the modified Tersoff potential function form in which the angular-dependent term is improved. The model performs extremely well in describing the crystalline, liquid, and amorphous phases (Schelling).

Only a single pair_coeff command is used with the tersoff/mod style which specifies a Tersoff/MOD potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of Tersoff/MOD elements to atom types

As an example, imagine the Si.tersoff_mod file has Tersoff values for Si. If your LAMMPS simulation has 3 Si atoms types, you would use the following pair_coeff command:

```
pair_coeff * * Si.tersoff_mod Si Si Si
```

The first 2 arguments must be ** so as to span all LAMMPS atom types. The three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the Tersoff/MOD file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a tersoff/mod potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.
Tersoff/MOD file in the potentials directory of the LAMMPS distribution have a “.tersoff.mod” suffix. Potential files for the tersoff/mod/c style have the suffix “.tersoff.modc”. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to coefficients in the formulae above:

- element 1 (the center atom in a 3-body interaction)
- element 2 (the atom bonded to the center atom)
- element 3 (the atom influencing the 1-2 bond in a bond-order sense)
- $\beta$
- $\alpha$
- $h$
- $\eta$
- $\beta_{\text{ers}} = 1$ (dummy parameter)
- $\lambda_2$ (1/distance units)
- $B$ (energy units)
- $R$ (distance units)
- $D$ (distance units)
- $\lambda_1$ (1/distance units)
- $A$ (energy units)
- $n$
- $c_1$
- $c_2$
- $c_3$
- $c_4$
- $c_5$
- $c_0$ (energy units, tersoff/mod/c only):ul

The $n$, $\eta$, $\lambda_2$, $\lambda_1$, and $A$ parameters are only used for two-body interactions. The $\beta$, $\alpha$, $c_1$, $c_2$, $c_3$, $c_4$, $c_5$, $h$ parameters are only used for three-body interactions. The $R$ and $D$ parameters are used for both two-body and three-body interactions. The $c_0$ term applies to tersoff/mod/c only. The non-annotated parameters are unitless.

The Tersoff/MOD potential file must contain entries for all the elements listed in the pair_coeff command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g. SiSiSi). As annotated above, the first element in the entry is the center atom in a three-body interaction and it is bonded to the second atom and the bond is influenced by the third atom. Thus an entry for SiSiSi means Si bonded to a Si with another Si atom influencing the bond.

The shift keyword computes the energy $E$ of a system of atoms, whose formula is the same as the Tersoff potential. The only modification is that the original equilibrium bond length ($r_0$) of the system is shifted to $r_0 - \delta$. The minus sign arises because each radial distance $r$ is replaced by $r + \delta$. More information on this option is given on the main pair_tersoff page.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages.
The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script. See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

19.252.4 Mixing, shift, table, tail correction, restart, rRESPA info

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

19.252.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This pair style requires the newton setting to be “on” for pair interactions.

The shift keyword is not supported by the tersoff/gpu, tersoff/intel, tersoff/kk, tersoff/table or tersoff/table/omp variants.

The tersoff/mod potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the tersoff/mod pair style with any LAMMPS units, but you would need to create your own Tersoff/MOD potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

19.252.7 Default

none

19.253 pair_style tersoff/zbl command

Accelerator Variants: tersoff/zbl/gpu, tersoff/zbl/kk, tersoff/zbl/omp

19.253.1 Syntax

```
pair_style tersoff/zbl keywords values
```

- **keyword** = *shift*
  - *shift* value = *delta*
    - *delta* = negative shift in equilibrium bond length

19.253.2 Examples

```
pair_style tersoff/zbl
pair_coeff * * SiC.tersoff.zbl Si C Si
```

19.253.3 Description

The *tersoff/zbl* style computes a 3-body Tersoff potential (*Tersoff_1*) with a close-separation pairwise modification based on a Coulomb potential and the Ziegler-Biersack-Littmark universal screening function (*ZBL*), giving the energy
E of a system of atoms as

\[ E = \frac{1}{2} \sum_i \sum_{j \neq i} V_{ij} \]

\[ V_{ij} = (1 - f_F(r_{ij} + \delta))V^{ZBL}(r_{ij} + \delta) + f_F(r_{ij} + \delta)V^{Tersoff}(r_{ij} + \delta) \]

\[ f_F(r) = \frac{1}{1 + e^{-A_F(r-r_C)}} \]

\[ V^{ZBL}(r) = \frac{1}{4\pi\epsilon_0} \frac{Z_1 Z_2 e^2}{r} \phi(r/a) \]

\[ \phi(x) = 0.1818e^{-3.2x} + 0.5099e^{-0.9423x} + 0.2802e^{-0.4029x} + 0.02817e^{-0.2016x} \]

\[ V^{Tersoff}(r) = f_C(r) [f_R(r) + b_{ij} f_A(r)] \]

\[ f_C(r) = \begin{cases} 
\frac{1}{2} - \frac{1}{2} \sin \left( \frac{\pi}{2} \frac{r-R}{D} \right) & : r < R - D \\
0 & : r > R + D 
\end{cases} \]

\[ f_R(r) = A \exp(-\lambda_1 r) \]

\[ f_A(r) = -B \exp(-\lambda_2 r) \]

\[ b_{ij} = (1 + \beta^n \zeta_{ij}^n)^{-\frac{1}{n}} \]

\[ \zeta_{ij} = \sum_{k \neq i, j} f_C(r_{ik} + \delta) g(\theta_{ijk}) \exp[\lambda_3 m (r_{ij} - r_{ik})^m] \]

\[ g(\theta) = \gamma_{ijk} \left( 1 + \frac{c^2}{d^2} - \frac{c^2}{d^2 + (\cos \theta - \cos \theta_0)^2} \right) \]

The \( f_F \) term is a fermi-like function used to smoothly connect the ZBL repulsive potential with the Tersoff potential. There are 2 parameters used to adjust it: \( A_F \) and \( r_C \). \( A_F \) controls how “sharp” the transition is between the two, and \( r_C \) is essentially the cutoff for the ZBL potential.

For the ZBL portion, there are two terms. The first is the Coulomb repulsive term, with \( Z_1, Z_2 \) as the number of protons in each nucleus, \( e \) as the electron charge (1 for metal and real units) and \( \epsilon_0 \) as the permittivity of vacuum. The second part is the ZBL universal screening function, with \( a_0 \) being the Bohr radius (typically 0.529 Angstroms), and the remainder of the coefficients provided by the original paper. This screening function should be applicable to most systems. However, it is only accurate for small separations (i.e. less than 1 Angstrom).

For the Tersoff portion, \( f_R \) is a two-body term and \( f_A \) includes three-body interactions. The summations in the formula are over all neighbors \( J \) and \( K \) of atom \( I \) within a cutoff distance = \( R + D \).

\( \delta \) is an optional negative shift of the equilibrium bond length, as described below.

Only a single pair_coeff command is used with the tersoff/zbl style which specifies a Tersoff/ZBL potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying \( N \) additional arguments after the filename in the pair_coeff command, where \( N \) is the number of LAMMPS atom types:

- filename
- \( N \) element names = mapping of Tersoff/ZBL elements to atom types

See the pair_coeff page for alternate ways to specify the path for the potential file.
As an example, imagine the SiC.tersoff.zbl file has Tersoff/ZBL values for Si and C. If your LAMMPS simulation has 4 atom types and you want the first 3 to be Si, and the fourth to be C, you would use the following pair_coeff command:

```
pair_coeff * * SiC.tersoff Si Si Si C
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the Tersoff/ZBL file. The final C argument maps LAMMPS atom type 4 to the C element in the Tersoff/ZBL file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a `terssof/zbl` potential is used as part of the `hybrid` pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Tersoff/ZBL files in the `potentials` directory of the LAMMPS distribution have a “.tersoff.zbl” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to coefficients in the formula above:

- element 1 (the center atom in a 3-body interaction)
- element 2 (the atom bonded to the center atom)
- element 3 (the atom influencing the 1-2 bond in a bond-order sense)
- m
- γ
- λ₃ (1/distance units)
- c
- d
- cosθ₀ (can be a value < -1 or > 1)
- n
- β
- λ₂ (1/distance units)
- B (energy units)
- R (distance units)
- D (distance units)
- λ₁ (1/distance units)
- A (energy units)
- Zᵢ
- Zⱼ
- ZBLcut (distance units)
- ZBLexpscale (1/distance units)

The n, β, λ₂, B, λ₁, and A parameters are only used for two-body interactions. The m, γ, λ₃, c, d, and cosθ₀ parameters are only used for three-body interactions. The R and D parameters are used for both two-body and three-body interactions. The Zᵢ, Zⱼ, ZBLcut, ZBLexpscale parameters are used in the ZBL repulsive portion of the potential and in the Fermi-like function. The non-annotated parameters are unitless. The value of m must be 3 or 1.

The Tersoff/ZBL potential file must contain entries for all the elements listed in the pair_coeff command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCSi, SiCC, CSiSi, CsiC, CsiC, CCC), that specify Tersoff parameters for
all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.

As annotated above, the first element in the entry is the center atom in a three-body interaction and it is bonded to the second atom and the bond is influenced by the third atom. Thus an entry for SiCC means Si bonded to a C with another C atom influencing the bond. Thus three-body parameters for SiCSi and SiSiC entries will not, in general, be the same. The parameters used for the two-body interaction come from the entry where the second element is repeated. Thus the two-body parameters for Si interacting with C, comes from the SiCC entry.

The parameters used for a particular three-body interaction come from the entry with the corresponding three elements. The parameters used only for two-body interactions (n, β, λ₂, B, λ₁, and A) in entries whose second and third element are different (e.g. SiCSi) are not used for anything and can be set to 0.0 if desired.

Note that the two-body parameters in entries such as SiCC and CSiSi are often the same, due to the common use of symmetric mixing rules, but this is not always the case. For example, the beta and n parameters in Tersoff_2 are not symmetric.

We chose the above form so as to enable users to define all commonly used variants of the Tersoff portion of the potential. In particular, our form reduces to the original Tersoff form when m = 3 and gamma = 1, while it reduces to the form of Albe et al. when beta = 1 and m = 1. Note that in the current Tersoff implementation in LAMMPS, m must be specified as either 3 or 1. Tersoff used a slightly different but equivalent form for alloys, which we will refer to as Tersoff_2 potential (Tersoff_2).

LAMMPS parameter values for Tersoff_2 can be obtained as follows: \(\gamma = \omega_{ijk}\), \(\lambda_3 = 0\) and the value of m has no effect. The parameters for species i and j can be calculated using the Tersoff_2 mixing rules:

\[
\begin{align*}
\lambda_i^{1,j} &= \frac{1}{2}(\lambda_i^1 + \lambda_j^1) \\
\lambda_i^{2,j} &= \frac{1}{2}(\lambda_i^2 + \lambda_j^2) \\
A_{i,j} &= (A_iA_j)^{1/2} \\
B_{i,j} &= \chi_{ij}(B_iB_j)^{1/2} \\
R_{i,j} &= (R_iR_j)^{1/2} \\
S_{i,j} &= (S_iS_j)^{1/2}
\end{align*}
\]

Tersoff_2 parameters R and S must be converted to the LAMMPS parameters R and D (R is different in both forms), using the following relations: \(R=(R'+S')/2\) and \(D=(S'-R')/2\), where the primes indicate the Tersoff_2 parameters.

In the potentials directory, the file SiCGe tersoff provides the LAMMPS parameters for Tersoff’s various versions of Si, as well as his alloy parameters for Si, C, and Ge. This file can be used for pure Si, (three different versions), pure C, pure Ge, binary SiC, and binary SiGe. LAMMPS will generate an error if this file is used with any combination involving C and Ge, since there are no entries for the GeC interactions (Tersoff did not publish parameters for this cross-interaction.) Tersoff files are also provided for the SiC alloy (SiC tersoff) and the GaN (GaN tersoff) alloys.

Many thanks to Rutuparna Narulkar, David Farrell, and Xiaowang Zhou for helping clarify how Tersoff parameters for alloys have been defined in various papers. Also thanks to Ram Devanathan for providing the base ZBL implementation.

The shift keyword computes the energy \(E\) of a system of atoms, whose formula is the same as the Tersoff potential. The only modification is that the original equilibrium bond length \(r_0\) of the system is shifted to \(r_0 - \delta\). The minus sign arises because each radial distance \(r\) is replaced by \(r + \delta\). More information on this option is given on the main pair_tersoff page.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.
These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 19.253.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

### 19.253.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This pair style requires the newton setting to be “on” for pair interactions.

The shift keyword is currently not supported for the tersoff/gpu and tersoff/kk variants of this pair style.

The tersoff/zbl potential files provided with LAMMPS (see the potentials directory) are parameterized for “metal” units. Also the pair style supports converting potential file parameters on-the-fly between “metal” and “real” units. You can use the tersoff/zbl pair style with any LAMMPS units, but you would need to create your own tersoff/zbl potential file with coefficients listed in the appropriate units if your simulation does not use “metal” or “real” units.

- args = list of arguments for a particular style

.thole args = damp cutoff
  damp = global damping parameter
  cutoff = global cutoff (distance units)

.lj/cut/thole/long args = damp cutoff (cutoff2)
  damp = global damping parameter
  cutoff = global cutoff for LJ (and Thole if only 1 arg) (distance units)
  cutoff2 = global cutoff for Thole (optional) (distance units)

19.255.2 Examples

.pair_style hybrid/overlay ... thole 2.6 12.0
.pair_coeff 1 1 thole 1.0
.pair_coeff 1 2 thole 1.0 2.6 10.0
.pair_coeff * 2 thole 1.0 2.6
.pair_style lj/cut/thole/long 2.6 12.0

Example input scripts available: examples/PACKAGES/drude

19.255.3 Description

The thole pair styles are meant to be used with force fields that include explicit polarization through Drude dipoles. This link describes how to use the thermalized Drude oscillator model in LAMMPS and polarizable models in LAMMPS are discussed on the Howto polarizable doc page.

The thole pair style should be used as a sub-style within the pair_style hybrid/overlay command, in conjunction with a main pair style including Coulomb interactions, i.e. any pair style containing coul/cut or coul/long in its style name.

The lj/cut/thole/long pair style is equivalent to, but more convenient that the frequent combination hybrid/overlay lj/cut/coul/long cutoff thole damp cutoff2. It is not only a shorthand for this pair_style combination, but it also allows for mixing pair coefficients instead of listing them all. The lj/cut/thole/long pair style is also a bit faster because it avoids an overlay and can benefit from OMP acceleration. Moreover, it uses a more precise approximation of the direct Coulomb interaction at short range similar to coul/long/cs, which stabilizes the temperature of Drude particles.

The thole pair styles compute the Coulomb interaction damped at short distances by a function

\[ T_{ij}(r_{ij}) = 1 - \left( 1 + \frac{s_{ij}r_{ij}}{2} \right) \exp \left( -s_{ij}r_{ij} \right) \]
This function results from an adaptation to point charges (Noskov) of the dipole screening scheme originally proposed by Thole. The scaling coefficient $s_{ij}$ is determined by the polarizability of the atoms, $\alpha_i$, and by a Thole damping parameter $a$. This Thole damping parameter usually takes a value of 2.6, but in certain force fields the value can depend upon the atom types. The mixing rule for Thole damping parameters is the arithmetic average, and for polarizabilities the geometric average between the atom-specific values.

$$s_{ij} = \frac{a_{ij}}{(\alpha_{ij})^{1/3}} = \frac{(a_i + a_j)/2}{[(\alpha_i\alpha_j)^{1/2}]^{1/3}}$$

The damping function is only applied to the interactions between the point charges representing the induced dipoles on polarizable sites, that is, charges on Drude particles, $q_{D,i}$, and opposite charges, $-q_{D,i}$, located on the respective core particles (to which each Drude particle is bonded). Therefore, Thole screening is not applied to the full charge of the core particle $q_i$, but only to the $-q_{D,i}$ part of it.

The interactions between core charges are subject to the weighting factors set by the special_bonds command. The interactions between Drude particles and core charges or non-polarizable atoms are also subject to these weighting factors. The Drude particles inherit the 1-2, 1-3 and 1-4 neighbor relations from their respective cores.

For pair_style thole, the following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the example above.

- $\alpha$ (distance units$^3$)
- damp
- cutoff (distance units)

The last two coefficients are optional. If not specified the global Thole damping parameter or global cutoff specified in the pair_style command are used. In order to specify a cutoff (third argument) a damp parameter (second argument) must also be specified.

For pair style lj/cut/thole/long, the following coefficients must be defined for each pair of atoms types via the pair_coeff command.

- $\epsilon$ (energy units)
- $\sigma$ (length units)
- $\alpha$ (distance units$^3$)
- damp
- LJ cutoff (distance units)

The last two coefficients are optional and default to the global values from the pair_style command line.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
19.255.4 Mixing, shift, table, tail correction, restart, rRESPA info

The \textit{thole} pair style does not support mixing. Thus, coefficients for all IJ pairs must be specified explicitly. The \textit{lj/cut/thole/long} pair style does support mixing. Mixed coefficients are defined using

\[
\alpha_{ij} = \sqrt{\alpha_i \alpha_j}
\]

\[
a_{ij} = \frac{1}{2} (a_i + a_j)
\]

19.255.5 Restrictions

These pair styles are part of the DRUDE package. They are only enabled if LAMMPS was built with that package. See the \textit{Build package} page for more info.

This pair\_style should currently not be used with the \textit{charmm dihedral style} if the latter has non-zero 1-4 weighting factors. This is because the \textit{thole} pair style does not know which pairs are 1-4 partners of which dihedrals.

The \textit{lj/cut/thole/long} pair style should be used with a \textit{Kspace solver} like PPPM or Ewald, which is only enabled if LAMMPS was built with the kspace package.

```

Used in example input scripts:

```plaintext
examples/PACKAGES/manybody_table/in.spce
examples/PACKAGES/manybody_table/in.spce2
```

19.256.3 Description

The `threebody/table` style is a pair style for generic tabulated three-body interactions. It has been developed for (coarse-grained) simulations (of water) with Kernel-based machine learning (ML) potentials (Scherer). As for many other MANYBODY package pair styles the energy of a system is computed as a sum over three-body terms:

\[
E = \sum_i \sum_{j \neq i} \sum_{k > j} \phi_3(r_{ij}, r_{ik}, \theta_{ijk})
\]

The summations in the formula are over all neighbors J and K of atom I within a cutoff distance \(cut\). In contrast to the Stillinger-Weber potential, all forces are not calculated analytically, but read in from a three-body force/energy table which can be generated with the csg_ml app of VOTCA as available at: https://gitlab.mpcdf.mpg.de/votca/votca.

Only a single `pair_coeff` command is used with the `threebody/table` style which specifies a three-body potential (“.3b”) file with parameters for all needed elements. These are then mapped to LAMMPS atom types by specifying \(N_{el}\) additional arguments after the “.3b” filename in the `pair_coeff` command, where \(N_{el}\) is the number of LAMMPS atom types:

- “.3b” filename
- \(N_{el}\) element names = mapping of threebody elements to atom types

See the `pair_coeff` page for alternate ways to specify the path for the potential file.

As an example, imagine a file SiC.3b has three-body values for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following `pair_coeff` command:

```plaintext
pair_coeff * * SiC.3b Si Si Si C
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the “.3b” file. The final C argument maps LAMMPS atom type 4 to the C element in the threebody file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a `threebody/table` potential is used as part of the `hybrid` pair style. The NULL values are placeholders for atom types that will be used with other potentials.

The three-body files have a “.3b” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry specify to the (three-body) cutoff distance and the tabulated three-body interaction. A single entry then contains:

- element 1 (the center atom in a 3-body interaction)
- element 2
- element 3
The parameter \textit{cut} is the (three-body) cutoff distance. When set to 0, no interaction is calculated for this element triplet. The parameters \textit{filename}, \textit{keyword}, \textit{style}, and \textit{N} refer to the tabulated three-body potential.

The tabulation is done on a three-dimensional grid of the two distances \( r_{ij} \) and \( r_{ik} \) as well as the angle \( \theta_{ijk} \) which is constructed in the following way. There are two different cases. If element 2 and element 3 are of the same type (e.g. SiCC), the distance \( r_{ij} \) is varied in “N” steps from \( r_{\text{min}} \) to \( r_{\text{max}} \) and the distance \( r_{ik} \) is varied from \( r_{ij} \) to \( r_{\text{max}} \). This can be done, due to the symmetry of the triplet. If element 2 and element 3 are not of the same type (e.g. SiCSi), there is no additional symmetry and the distance \( r_{ik} \) is also varied from \( r_{\text{min}} \) to \( r_{\text{max}} \) in “N” steps. The angle \( \theta_{ijk} \) is always varied in “2N” steps from \((0.0 + 180.0/(4N))\) to \((180.0 - 180.0/(4N))\). Therefore, the total number of table entries is “\( M = N * N * (N+1) \)” for the symmetric (element 2 and element 3 are of the same type) and “\( M = 2 * N * N * N \)” for the general case (element 2 and element 3 are not of the same type).

The forces on all three particles \( I, J, \) and \( K \) of a triplet of this type of three-body interaction potential \( (\varphi_3(r_{ij}, r_{ik}, \theta_{ijk})) \) lie within the plane defined by the three inter-particle distance vectors \( r_{ij}, r_{ik}, \) and \( r_{jk} \). This property is used to project the forces onto the inter-particle distance vectors as follows

\[
\begin{pmatrix}
  f_i \\
  f_j \\
  f_k
\end{pmatrix} =
\begin{pmatrix}
  f_{i1} & f_{i2} & 0 \\
  f_{j1} & 0 & f_{j2} \\
  0 & f_{k1} & f_{k2}
\end{pmatrix}
\begin{pmatrix}
  r_{ij} \\
  r_{ik} \\
  r_{jk}
\end{pmatrix}
\]

and then tabulate the 6 force constants \( f_{i1}, f_{i2}, f_{j1}, f_{j2}, f_{k1}, \) and \( f_{k2} \), as well as the energy of a triplet \( e \). Due to symmetry reasons, the following relations hold: \( f_{i1} = -f_{j1}, f_{i2} = -f_{k1}, \) and \( f_{j2} = -f_{k2} \). As in this pair style the forces are read in directly, a correct MD simulation is also performed in the case that the triplet energies are set to \( e = 0 \).

The \textit{filename} specifies the file containing the tabulated energy and derivative values of \( \varphi_3(r_{ij}, r_{ik}, \theta_{ijk}) \). The \textit{keyword} then specifies a section of the file. The format of this file is as follows (without the parenthesized comments):

```
# Tabulated three-body potential for spce water (one or more comment or blank lines)

```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “\( N \)” is required. It should be the same than the parameter “\( N \)” of the “.3b” file, otherwise its value is overwritten. “\( N \)” determines the number of table entries “\( M \)” that follow: “\( M = N * N * (N+1) \)” (symmetric triplet, e.g. SiCC) or “\( M = 2 * N * N * N \)” (asymmetric triplet, e.g. SiCSi). Therefore “\( M = 12 * 12 * 13 = 1872 \)” in the above
symmetric example. The parameters “rmin” and “rmax” are also required and determine the minimum and maximum of the inter-particle distances $r_{ij}$ and $r_{ik}$.

Following a blank line, the next M lines of the angular table file list the tabulated values. On each line, the first value is the index from 1 to M, the second value is the distance $r_{ij}$, the third value is the distance $r_{ik}$, the fourth value is the angle $\theta_{ijk}$, the next six values are the force constants $f_{i1}$, $f_{i2}$, $f_{j1}$, $f_{j2}$, $f_{k1}$, and $f_{k2}$, and the last value is the energy e.

Note that one three-body potential file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword of appropriate section of the “.3b” file.

At the moment, only the style linear is allowed and implemented. After reading in the force table, it is internally stored in LAMMPS as a lookup table. For each triplet configuration occurring in the simulation within the cutoff distance, the next nearest tabulated triplet configuration is looked up. No interpolation is done. This allows for a very efficient force calculation with the stored force constants and energies. Due to the know table structure, the lookup can be done efficiently. It has been tested (Scherer2) that with a reasonably small bin size, the accuracy and speed is comparable to that of a Stillinger-Weber potential with tabulated three-body interactions (pair_style sw/angle/table) while the table format of this pair style allows for more flexible three-body interactions.

As for the Stillinger-Weber potential, the three-body potential file must contain entries for all the elements listed in the pair_coeff command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries.

For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCSI, SiCC, CSI, CSI, CCSi, CCC), that specify threebody parameters for all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.

As annotated above, the first element in the entry is the center atom in a three-body interaction. Thus an entry for SiCC means a Si atom with 2 C atoms as neighbors. The tabulated three-body forces can in principle be specific to the three elements of the configuration. However, the user must ensure that it makes physically sense. E.g., the tabulated three-body forces for the entries CSiC and CCSi should be the same exchanging $r_{ij}$ with $r_{ik}$, $f_{j1}$ with $f_{k1}$, and $f_{j2}$ with $f_{k2}$.

Additional input files and reference data can be found at: https://gitlab.mpcdf.mpg.de/votca/votca/-/tree/master/csg-tutorials/ml

19.256.4 Mixing, shift, table, tail correction, restart, rRESPA info

As all interactions are tabulated, no mixing is performed.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files, since it is stored in potential files. Thus, you need to re-specify the pair_style and pair_coeff commands in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.
19.256.5 Restrictions

This pair style is part of the MANYBODY package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This pair style requires the newton setting to be “on” for pair interactions.

19.256.6 Related commands

pair_coeff, pair sw/angle/table

19.257 pair_style tracker command

19.257.1 Syntax

```
pair_style tracker fix_ID N keyword values attribute1 attribute2 ...
```

- fix_ID = ID of associated internal fix to store data
- N = prepare data for output every this many timesteps
- zero or more keywords may be appended
- keyword = finite or time/min or type/include
  - finite value = none
    - pair style uses atomic diameters to identify contacts
  - time/min value = T
    - T = minimum number of timesteps of interaction
  - type/include value = list1 list2
    - list1, list2 = separate lists of types (see below)
- one or more attributes may be appended

```
possible attributes = id1 id2 time/created time/broken time/total
  r/min r/ave x y z
```

id1, id2 = IDs of the 2 atoms in each pair interaction
- time/created = the timestep that the 2 atoms began interacting
- time/broken = the timestep that the 2 atoms stopped interacting
- time/total = the total number of timesteps the 2 atoms interacted
- r/min = the minimum radial distance between the 2 atoms during the interaction
  - (distance units)
- r/ave = the average radial distance between the 2 atoms during the interaction
  - (distance units)
- x, y, z = the center of mass position of the 2 atoms when they stopped interacting
  - (distance units)
19.257.2 Examples

```
pair_style hybrid/overlay tracker myfix 1000 id1 id2 type/include 1 * type/include 2 3,4
   lj/cut 2.5
pair_coeff 1 1 tracker 2.0

pair_style hybrid/overlay tracker myfix 1000 finite x y z time/min 100 granular
pair_coeff * * tracker

dump_modify 1 write_header no
```

19.257.3 Description

Style *tracker* monitors information about pairwise interactions. It does not calculate any forces on atoms. *Pair hybrid/overlay* can be used to combine this pair style with any other pair style, as shown in the examples above.

At each timestep, if two neighboring atoms move beyond the interaction cutoff, pairwise data is processed and transferred to an internal fix labeled *fix_ID*. This allows the local data to be accessed by other LAMMPS commands. Additional filters can be applied using the *time/min* or *type/include* keywords described below. Note that this is the interaction cutoff defined by this pair style, not the short-range cutoff defined by the pair style that is calculating forces on atoms.

Following any optional keyword/value arguments, a list of one or more attributes is specified. These include the IDs of the two atoms in the pair. The other attributes for the pair of atoms are the duration of time they were “interacting” or at the point in time they started or stopped interacting. In this context, “interacting” means the time window during which the two atoms were closer than the interaction cutoff distance. The attributes for *time/* refer to timesteps.

Data is continuously accumulated by the internal fix over intervals of *N* timesteps. At the end of each interval, all of the saved accumulated data is deleted to make room for new data. Individual datum may therefore persist anywhere between 1 to *N* timesteps depending on when they are saved. This data can be accessed using the *fix_ID* and a *dump local* command. To ensure all data is output, the dump frequency should correspond to the same interval of *N* timesteps. A dump frequency of an integer multiple of *N* can be used to regularly output a sample of the accumulated data.

The following optional keywords may be used.

If the *finite* keyword is not used, the following coefficients must be defined for each pair of atom types via the *pair_coeff* command as in the examples above, or in the data file or restart files read by the *read_data* or *read_restart* commands, or by mixing as described below:

- **cutoff** (distance units)

If the *finite* keyword is used, there are no additional coefficients to set for each pair of atom types via the *pair_coeff* command. Interaction cutoffs are instead calculated based on the diameter of finite particles. However you must still use the *pair_coeff* for all atom types. For example the command

```
pair_coeff * *
```

should be used.

The *time/min* keyword sets a minimum amount of time that an interaction must persist to be included. This setting can be used to censor short-lived interactions.

The *type/include* keyword filters interactions based on the types of the two atoms. Data is only saved for interactions between atoms whose two atom types appear in *list1* and *list2*. Atom type 1 must be in *list1* and atom type 2 in *list2*. Or vice versa.
Each type list consists of a series of type ranges separated by commas. Each range can be specified as a single numeric value, or a wildcard asterisk can be used to specify a range of values. This takes the form "*" or "n*" or "*n" or "m*n". For example, if \( M \) = the number of atom types, then an asterisk with no numeric values means all types from 1 to \( M \). A leading asterisk means all types from 1 to \( n \) (inclusive). A trailing asterisk means all types from \( n \) to \( M \) (inclusive). A middle asterisk means all types from \( m \) to \( n \) (inclusive). Note that the type/include keyword can be specified multiple times.

### 19.257.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs \( I,J \) and \( I \neq J \), the cutoff coefficient and cutoff distance for this pair style can be mixed. The cutoff is always mixed via a geometric rule. The cutoff is mixed according to the pair_modify mix value. The default mix value is geometric. See the "pair_modify" command for details.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

The pair_modify shift, table, and tail options are not relevant for this pair style.

The accumulated data is not written to restart files and should be output before a restart file is written to avoid missing data.

The internal fix calculates a local vector or local array depending on the number of input values. The length of the vector or number of rows in the array is the number of recorded, lost interactions. If a single input is specified, a local vector is produced. If two or more inputs are specified, a local array is produced where the number of columns = the number of inputs. The vector or array can be accessed by any command that uses local values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The vector or array will be floating point values that correspond to the specified attribute.

### 19.257.5 Restrictions

This fix is part of the MISC package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

This pair style is currently incompatible with granular pair styles that extend beyond the contact (e.g. JKR and DMT).

### 19.257.6 Related commands

### 19.257.7 Default

none

### 19.258 pair_style tri/lj command

#### 19.258.1 Syntax

```
pair_style tri/lj cutoff
cutoff = global cutoff for interactions (distance units)
```
19.258.2 Examples

```
pair_style tri/lj 3.0
pair_coeff * * 1.0 1.0
pair_coeff 1 1 1.0 1.5 2.5
```

19.258.3 Description

Style `tri/lj` treats particles which are triangles as a set of small spherical particles that tile the triangle surface as explained below. Interactions between two triangles, each with N1 and N2 spherical particles, are calculated as the pairwise sum of N1*N2 Lennard-Jones interactions. Interactions between a triangle with N spherical particles and a point particle are treated as the pairwise sum of N Lennard-Jones interactions. See the `pair_style lj/cut` doc page for the definition of Lennard-Jones interactions.

The cutoff distance for an interaction between 2 triangles, or between a triangle and a point particle, is calculated from the position of the triangle (its centroid), not between pairs of individual spheres comprising the triangle. Thus an interaction is either calculated in its entirety or not at all.

The set of non-overlapping spherical particles that represent a triangle, for purposes of this pair style, are generated in the following manner. Assume the triangle is of type I, and sigma_{II} has been specified. We want a set of spheres with centers in the plane of the triangle, none of them larger in diameter than sigma_{II}, which completely cover the triangle's area, but with minimal overlap and a minimal total number of spheres. This is done in a recursive manner. Place a sphere at the centroid of the original triangle. Calculate what diameter it must have to just cover all 3 corner points of the triangle. If that diameter is equal to or smaller than sigma_{II}, then include a sphere of the calculated diameter in the set of covering spheres. If the diameter is larger than sigma_{II}, then split the triangle into 2 triangles by bisecting its longest side. Repeat the process on each sub-triangle, recursing as far as needed to generate a set of covering spheres. When finished, the original criteria are met, and the set of covering spheres should be near minimal in number and overlap, at least for input triangles with a reasonable aspect-ratio.

The LJ interaction between 2 spheres on different triangles of types I,J is computed with an arithmetic mixing of the sigma values of the 2 spheres and using the specified epsilon value for I,J atom types. Note that because the sigma values for triangles spheres is computed using only sigma_{II} values, specific to the triangles's type, this means that any specified sigma_{IJ} values (for I != J) are effectively ignored.

For style `tri/lj`, the following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- epsilon (energy units)
- sigma (distance units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global cutoff is used.
19.258.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I ≠ J, the epsilon and sigma coefficients and cutoff distance for all of this pair style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the pair_modify shift, table, and tail options.

This pair style does not write its information to binary restart files.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

19.258.5 Restrictions

This style is part of the ASPHERE package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

Defining particles to be triangles so they participate in tri/tri or tri/particle interactions requires the use the atom_style tri command.

19.258.6 Related commands

pair_coeff, pair_style line/lj

19.258.7 Default

none

19.259 pair_style ufm command

Accelerator Variants: ufm/gpu, ufm/omp, ufm/opt

19.259.1 Syntax

```
pair_style ufm cutoff
```

- cutoff = global cutoff for ufm interactions (distance units)

19.259.2 Examples

```
pair_style ufm 4.0
pair_coeff 1 1 100.0 1.0 2.5
pair_coeff * * 100.0 1.0

pair_style ufm 4.0
pair_coeff * * 10.0 1.0
variable prefactor equal ramp(10,100)
fix 1 all adapt 1 pair ufm epsilon * * v_prefactor
```
19.259.3 Description

Style *ufm* computes pairwise interactions using the Uhlenbeck-Ford model (UFM) potential *(Paula Leite2016)* which is given by

\[
E = -\epsilon \ln \left[ 1 - \exp \left( -r^2 / \sigma^2 \right) \right] \quad r < r_c
\]

\[
\epsilon = p k_B T
\]

where \( r_c \) is the cutoff, \( \sigma \) is a distance-scale and \( \epsilon \) is an energy-scale, i.e., a product of Boltzmann constant \( k_B \), temperature \( T \) and the Uhlenbeck-Ford \( p \)-parameter which is responsible to control the softness of the interactions *(Paula Leite2017)*. This model is useful as a reference system for fluid-phase free-energy calculations *(Paula Leite2016)*.

The following coefficients must be defined for each pair of atom types via the *pair_coeff* command as in the examples above, or in the data file or restart files read by the *read_data* or *read_restart* commands, or by mixing as described below:

- \( \epsilon \) (energy units)
- \( \sigma \) (distance units)
- cutoff (distance units)

The last coefficient is optional. If not specified, the global *ufm* cutoff is used.

The *fix adapt* command can be used to vary epsilon and sigma for this pair style over the course of a simulation, in which case *pair_coeff* settings for epsilon and sigma must still be specified, but will be overridden. For example these commands will vary the prefactor epsilon for all pairwise interactions from 10.0 at the beginning to 100.0 at the end of a run:

```
variable prefactor equal ramp(10,100)
fix 1 all adapt 1 pair ufm epsilon * * v_prefactor
```

**Note:** The thermodynamic integration procedure can be performed with this potential using *fix adapt*. This command will rescale the force on each atom by varying a scale variable, which always starts with value 1.0. The syntax is the same described above, however, changing epsilon to scale. A detailed explanation of how to use this command and perform nonequilibrium thermodynamic integration in LAMMPS is given in the paper by *(Freitas)*.

---

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the *-suffix* command-line switch when you invoke LAMMPS, or you can use the *suffix* command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
19.259.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the epsilon and sigma coefficients and cutoff distance for this pair style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style support the pair_modify shift option for the energy of the pair interaction.

The pair_modify table and tail are not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

19.259.5 Restrictions

This pair style is part of the EXTRA-PAIR package. It is only enabled if LAMMPS was built with that package. See the Build package page for more info.

\textbf{pair\_coeff} * * SiC.vashishta Si C
\end{verbatim}
```

### 19.261.3 Description

The \textit{vashishta} and \textit{vashishta/table} styles compute the combined 2-body and 3-body family of potentials developed in the group of Priya Vashishta and collaborators. By combining repulsive, screened Coulombic, screened charge-dipole, and dispersion interactions with a bond-angle energy based on the Stillinger-Weber potential, this potential has been used to describe a variety of inorganic compounds, including SiO\textsubscript{2} \cite{Vashishta1990}, SiC \cite{Vashishta2007}, and InP \cite{Branicio2009}.

The potential for the energy \(U\) of a system of atoms is

\[
U = \sum_{i}^{N} \sum_{j > i}^{N} U^{(2)}_{ij}(r_{ij}) + \sum_{i}^{N} \sum_{j 
eq i}^{N} \sum_{k > j, k 
eq i}^{N} U^{(3)}_{ijk}(r_{ij}, r_{ik}, \theta_{ijk})
\]

\[
U^{(2)}_{ij}(r) = \frac{H_{ij}}{r_{ij}} + \frac{Z_{i}Z_{j}}{r} \exp(-r/\lambda_{1,ij}) - \frac{D_{ij}}{r^4} \exp(-r/\lambda_{4,ij}) - \frac{W_{ij}}{r^6}, r < r_{c,ij}
\]

\[
U^{(3)}_{ijk}(r_{ij}, r_{ik}, \theta_{ijk}) = B_{ijk} \left[ \frac{\cos \theta_{ijk} - \cos \theta_{0ij}}{1 + C_{ijk} \left[ \cos \theta_{ijk} - \cos \theta_{0ijk} \right]^2} \right] \times 
\exp \left( \frac{\gamma_{ij}}{r_{ij} - r_{0,ij}} \right) \exp \left( \frac{\gamma_{ik}}{r_{ik} - r_{0,ik}} \right), r_{ij} < r_{0,ij}, r_{ik} < r_{0,ik}
\]

where we follow the notation used in \cite{Branicio2009}. \(U^{2}\) is a two-body term and \(U^{3}\) is a three-body term. The summation over two-body terms is over all neighbors \(J\) within a cutoff distance = \(r_{c}\). The two-body terms are shifted and tilted by a linear function so that the energy and force are both zero at \(r_{c}\). The summation over three-body terms is over all neighbors \(i\) and \(k\) within a cut-off distance = \(r_{0}\), where the exponential screening function becomes zero.

The \textit{vashishta} style computes these formulas analytically. The \textit{vashishta/table} style tabulates the analytic values for \textit{Ntable} points from cutinner to the cutoff of the potential. The points are equally spaced in \(R^2\) space from cutinner^2 to cutoff^2. For the two-body term in the above equation, a linear interpolation for each pairwise distance between adjacent points in the table. In practice the tabulated version can run 3-5x faster than the analytic version with moderate to little loss of accuracy for \textit{Ntable} values between 10000 and 1000000. It is not recommended to use less than 5000 tabulation points.
Only a single pair_coeff command is used with either style which specifies a Vashishta potential file with parameters for all needed elements. These are mapped to LAMMPS atom types by specifying N additional arguments after the filename in the pair_coeff command, where N is the number of LAMMPS atom types:

- filename
- N element names = mapping of Vashishta elements to atom types

See the pair_coeff page for alternate ways to specify the path for the potential file.

As an example, imagine a file SiC.vashishta has parameters for Si and C. If your LAMMPS simulation has 4 atoms types and you want the first 3 to be Si, and the fourth to be C, you would use the following pair_coeff command:

```
pair_coeff * * SiC.vashishta Si Si Si C
```

The first 2 arguments must be * * so as to span all LAMMPS atom types. The first three Si arguments map LAMMPS atom types 1,2,3 to the Si element in the file. The final C argument maps LAMMPS atom type 4 to the C element in the file. If a mapping value is specified as NULL, the mapping is not performed. This can be used when a vashishta potential is used as part of the hybrid pair style. The NULL values are placeholders for atom types that will be used with other potentials.

Vashishta files in the potentials directory of the LAMMPS distribution have a “.vashishta” suffix. Lines that are not blank or comments (starting with #) define parameters for a triplet of elements. The parameters in a single entry correspond to the two-body and three-body coefficients in the formulae above:

- element 1 (the center atom in a 3-body interaction)
- element 2
- element 3
- $H$ (energy units)
- $\eta$
- $Z_i$ (electron charge units)
- $Z_j$ (electron charge units)
- $\lambda_1$ (distance units)
- $D$ (energy units)
- $\lambda_4$ (distance units)
- $W$ (energy units)
- $r_c$ (distance units)
- $B$ (energy units)
- $\gamma$
- $r_0$ (distance units)
- $C$
- $\cos \theta_0$

The non-annotated parameters are unitless. The Vashishta potential file must contain entries for all the elements listed in the pair_coeff command. It can also contain entries for additional elements not being used in a particular simulation; LAMMPS ignores those entries. For a single-element simulation, only a single entry is required (e.g. SiSiSi). For a two-element simulation, the file must contain 8 entries (for SiSiSi, SiSiC, SiCSi, SiCC, CSiSi, CSiC, CCSi, CCC), that specify parameters for all permutations of the two elements interacting in three-body configurations. Thus for 3 elements, 27 entries would be required, etc.
Depending on the particular version of the Vashishta potential, the values of these parameters may be keyed to the identities of zero, one, two, or three elements. In order to make the input file format unambiguous, general, and simple to code, LAMMPS uses a slightly confusing method for specifying parameters. All parameters are divided into two classes: two-body and three-body. Two-body and three-body parameters are handled differently, as described below. The two-body parameters are \( H, \eta, \lambda_1, D, \omega, \gamma, \) and \( r_0 \). They appear in the above formulae with two subscripts. The parameters \( Z_i \) and \( Z_j \) are also classified as two-body parameters, even though they only have 1 subscript. The three-body parameters are \( B, C, \cos \theta_0 \). They appear in the above formulae with three subscripts. Two-body and three-body parameters are handled differently, as described below.

The first element in each entry is the center atom in a three-body interaction, while the second and third elements are two neighbor atoms. Three-body parameters for a central atom I and two neighbors J and K are taken from the IJK entry. Note that even though three-body parameters do not depend on the order of J and K, LAMMPS stores three-body parameters for both IJK and IKJ. The user must ensure that these values are equal. Two-body parameters for an atom I interacting with atom J are taken from the IJJ entry, where the second and third elements are the same. Thus the two-body parameters for Si interacting with C come from the SiCC entry. Note that even though two-body parameters (except possibly gamma and \( r_0 \) in \( U_3 \)) do not depend on the order of the two elements, LAMMPS will get the Si-C value from the SiCC entry and the C-Si value from the CSIiSi entry. The user must ensure that these values are equal. Two-body parameters appearing in entries where the second and third elements are different are stored but never used. It is good practice to enter zero for these values. Note that the three-body function \( U_3 \) above contains the two-body parameters \( \gamma \) and \( r_0 \). So \( U_3 \) for a central C atom bonded to an Si atom and a second C atom will take three-body parameters from the CSIc entry, but two-body parameters from the CCC and CSIiSi entries.

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Accelerator packages} page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \textit{-suffix command-line switch} when you invoke LAMMPS, or you can use the \textit{suffix} command in your input script. See the \textit{Accelerator packages} page for more instructions on how to use the accelerated styles effectively.

### 19.261.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I \(!= J\), where types I and J correspond to two different element types, mixing is performed by LAMMPS as described above from values in the potential file.

This pair style does not support the \textit{pair_modify} shift, table, and tail options.

This pair style does not write its information to \textit{binary restart files}, since it is stored in potential files. Thus, you need to re-specify the \textit{pair_style} and \textit{pair_coeff} commands in an input script that reads a restart file.

This pair style can only be used via the \textit{pair} keyword of the \textit{run_style respa} command. It does not support the \textit{inner}, \textit{middle}, \textit{outer} keywords.
19.261.5 Restrictions

These pair styles are part of the MANYBODY package. They are only enabled if LAMMPS was built with that package. See the Build package page for more info.

These pair styles requires the newton setting to be “on” for pair interactions.

The Vashishta potential files provided with LAMMPS (see the potentials directory) are parameterized for metal units. You can use the Vashishta potential with any LAMMPS units, but you would need to create your own potential file with coefficients listed in the appropriate units if your simulation does not use “metal” units.

19.261.6 Related commands

pair_coeff

19.261.7 Default

none

19.262 pair_style wf/cut command

19.262.1 Syntax

```
pair_style wf/cut cutoff
```

- cutoff = cutoff for wf interactions (distance units)

19.262.2 Examples

```
pair_style    wf/cut  2.0
pair_coeff    1 1 1.0 1.0 1 1 2.0
```

19.262.3 Description

The `wf/cut` (Wang-Frenkel) style computes LJ-like potentials as described in Wang2020. This potential is by construction finite ranged and it vanishes quadratically at the cutoff distance, avoiding truncation, shifting, interpolation and other typical procedures with the LJ potential. The `wf/cut` can be used when a typical short-ranged potential with attraction is required. The potential is given by which is given by:

\[
\phi(r) = \epsilon \alpha \left( \left( \frac{\sigma}{r} \right)^{2\mu} - 1 \right) \left( \left( \frac{r_c}{r} \right)^{2\mu} - 1 \right)^{2\nu}
\]
with

$$\alpha = 2^\nu \left( \frac{r_c}{\sigma} \right)^{2\mu} \left[ \frac{1 + 2^\nu}{2^\nu \left( (r_c/\sigma)^{2^\mu} - 1 \right)} \right]^{2^\nu+1}$$

and

$$r_{\text{min}} = r_c \left[ \frac{1 + 2^\nu}{1 + 2^\nu (r_c/\sigma)^{2^\mu}} \right]^{1/2^\nu}$$

$r_c$ is the cutoff.

Comparison of the non-truncated Lennard-Jones 12-6 potential (red curve), and the WF potentials with $\mu = 1$ and $\nu = 1$ are shown in the figure below. The blue curve has $r_c = 2.0$ and the green curve has $r_c = 1.2$ and can be used to describe colloidal interactions.

The following coefficients must be defined for each pair of atoms types via the pair_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- $\epsilon$ (energy units)
- $\sigma$ (distance units)
- $\nu$
- $\mu$
- $r_c$ (distance units)

The last coefficient is optional. If not specified, the global cutoff given in the pair_style command is used. The exponents $\nu$ and $\mu$ are positive integers, usually set to 1. There is usually little to be gained by choosing other values of $\nu$ and $\mu$ (See discussion in Wang2020)

**Mixing, shift, table, tail correction, restart, rRESPA info:**

This pair style does not support the pair_modify mixing and table options.

The pair_modify tail option is not relevant for this pair style as it goes to zero at the cut-off radius.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style does not support the use of the inner, middle, and outer keywords of the run_style respa command.
19.262.4 Restrictions

This pair style can only be used if LAMMPS was built with the EXTRA-PAIR package. See the Build package doc page for more info.

```
pair_style yukawa 2.0 2.5
pair_coeff 1 1 100.0 2.3
pair_coeff * * 100.0
```

19.263.3 Description

Style `yukawa` computes pairwise interactions with the formula

\[
E = \frac{A e^{-\kappa r}}{r} \quad r < r_c
\]

\(r_c\) is the cutoff.

The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- A (energy*distance units)
- cutoff (distance units)
The last coefficient is optional. If not specified, the global yukawa cutoff is used.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 19.263.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs I,J and I != J, the A coefficient and cutoff distance for this pair style can be mixed. A is an energy value mixed like a LJ epsilon. The default mix value is geometric. See the “pair_modify” command for details.

This pair style supports the pair_modify shift option for the energy of the pair interaction.

The pair_modify table option is not relevant for this pair style.

This pair style does not support the pair_modify tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the pair keyword of the run_style respa command. It does not support the inner, middle, outer keywords.

### 19.263.5 Restrictions

none

### 19.263.6 Related commands

pair_coeff

### 19.263.7 Default

none
19.264 pair_style yukawa/colloid command

Accelerator Variants: yukawa/colloid/gpu, yukawa/colloid/omp

19.264.1 Syntax

```
pair_style yukawa/colloid kappa cutoff
```

- kappa = screening length (inverse distance units)
- cutoff = global cutoff for colloidal Yukawa interactions (distance units)

19.264.2 Examples

```
pair_style yukawa/colloid 2.0 2.5
pair_coeff 1 1 100.0 2.3
pair_coeff * * 100.0
```

19.264.3 Description

Style `yukawa/colloid` computes pairwise interactions with the formula

\[
E = \frac{A}{\kappa} e^{-\kappa(r_i + r_j)} \quad r < r_c
\]

where \(r_i\) and \(r_j\) are the radii of the two particles and \(r_c\) is the cutoff.

In contrast to `pair_style yukawa`, this functional form arises from the Coulombic interaction between two colloid particles, screened due to the presence of an electrolyte, see the book by Safran for a derivation in the context of DLVO theory. `Pair_style yukawa` is a screened Coulombic potential between two point-charges and uses no such approximation.

This potential applies to nearby particle pairs for which the Derjagin approximation holds, meaning \(h << r_i + r_j\), where \(h\) is the surface-to-surface separation of the two particles.

When used in combination with `pair_style colloid`, the two terms become the so-called DLVO potential, which combines electrostatic repulsion and van der Waals attraction.

The following coefficients must be defined for each pair of atom types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- A (energy/distance units)
- cutoff (distance units)

The prefactor \(A\) is determined from the relationship between surface charge and surface potential due to the presence of electrolyte. Note that the \(A\) for this potential style has different units than the \(A\) used in `pair_style yukawa`. For low surface potentials, i.e. less than about 25 mV, \(A\) can be written as:

\[
A = 2\pi \epsilon_0 \kappa \psi^2
\]

where

- \(R\) = colloid radius (distance units)
• \( \varepsilon_0 \) = permittivity of free space (charge^2/energy/distance units)
• \( \varepsilon \) = relative permittivity of fluid medium (dimensionless)
• \( \kappa \) = inverse screening length (1/distance units)
• \( \psi \) = surface potential (energy/charge units)

The last coefficient is optional. If not specified, the global yukawa/colloid cutoff is used.

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Accelerator packages} page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \textit{-suffix} command-line switch when you invoke LAMMPS, or you can use the \textit{suffix} command in your input script.

See the \textit{Accelerator packages} page for more instructions on how to use the accelerated styles effectively.

### 19.264.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs IJ and I \(!=\ J\), the A coefficient and cutoff distance for this pair style can be mixed. A is an energy value mixed like a LJ epsilon. The default mix value is geometric. See the “pair_modify” command for details.

This pair style supports the \textit{pair_modify} shift option for the energy of the pair interaction.

The \textit{pair_modify} table option is not relevant for this pair style.

This pair style does not support the \textit{pair_modify} tail option for adding long-range tail corrections to energy and pressure.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style can only be used via the \textit{pair} keyword of the \textit{run_style respa} command. It does not support the \textit{inner}, \textit{middle}, \textit{outer} keywords.

### 19.264.5 Restrictions

This style is part of the COLLOID package. It is only enabled if LAMMPS was built with that package. See the \textit{Build package} page for more info.

This pair style requires that atoms be finite-size spheres with a diameter, as defined by the \textit{atom_style sphere} command.

Per-particle polydispersity is not yet supported by this pair style; per-type polydispersity is allowed. This means all particles of the same type must have the same diameter. Each type can have a different diameter.
Related commands

pair_coeff

Default

none

pair_style zbl command

Accelerator Variants: zbl/gpu, zbl/kk, zbl/omp

Syntax

pair_style zbl inner outer

- inner = distance where switching function begins
- outer = global cutoff for ZBL interaction

Examples

pair_style zbl 3.0 4.0
pair_coeff * * 73.0 73.0
pair_coeff 1 1 14.0 14.0

Description

Style zbl computes the Ziegler-Biersack-Littmark (ZBL) screened nuclear repulsion for describing high-energy collisions between atoms. (Ziegler). It includes an additional switching function that ramps the energy, force, and curvature smoothly to zero between an inner and outer cutoff. The potential energy due to a pair of atoms at a distance r_ij is given by:

\[ E_{ZBL}^{ij} = \frac{1}{4\pi\epsilon_0} \frac{Z_iZ_je^2}{r_{ij}} \phi\left(\frac{r_{ij}}{a}\right) + S(r_{ij}) \]

\[ a = \frac{0.46850}{Z_i^{0.23} + Z_j^{0.23}} \]

\[ \phi(x) = 0.18175e^{-3.19980x} + 0.50986e^{-0.34229x} + 0.28022e^{-0.40290x} + 0.02817e^{-0.20162x} \]

where \( e \) is the electron charge, \( \epsilon_0 \) is the electrical permittivity of vacuum, and \( Z_i \) and \( Z_j \) are the nuclear charges of the two atoms. The switching function \( S(r) \) is identical to that used by pair_style lj/gromacs. Here, the inner and outer cutoff are the same for all pairs of atom types.

The following coefficients must be defined for each pair of atom types via the pair_coeff command as in the examples above, or in the LAMMPS data file.
- $Z_i$ (atomic number for first atom type, e.g. 13.0 for aluminum)
- $Z_j$ (ditto for second atom type)

The values of $Z_i$ and $Z_j$ are normally equal to the atomic numbers of the two atom types. Thus, the user may optionally specify only the coefficients for each $i \equiv i$ pair, and rely on the obvious mixing rule for cross interactions (see below). Note that when $i \equiv i$ it is required that $Z_i = Z_j$. When used with hybrid/overlay and pairs are assigned to more than one sub-style, the mixing rule is not used and each pair of types interacting with the ZBL sub-style must be included in a pair_coeff command.

**Note:** The numerical values of the exponential decay constants in the screening function depend on the unit of distance. In the above equation they are given for units of angstroms. LAMMPS will automatically convert these values to the distance unit of the specified LAMMPS `units` setting. The values of $Z$ should always be given as multiples of a proton’s charge, e.g. 29.0 for copper.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 19.265.4 Mixing, shift, table, tail correction, restart, rRESPA info

For atom type pairs $i,j$ and $i \neq i$, the $Z_i$ and $Z_j$ coefficients can be mixed by taking $Z_i$ and $Z_j$ from the values specified for $i \equiv i$ and $j \equiv j$ cases. When used with hybrid/overlay and pairs are assigned to more than one sub-style, the mixing rule is not used and each pair of types interacting with the ZBL sub-style must be included in a pair_coeff command. The `pair_modify` mix option has no effect on the mixing behavior.

The ZBL pair style does not support the `pair_modify` shift option, since the ZBL interaction is already smoothed to 0.0 at the cutoff.

The `pair_modify` table option is not relevant for this pair style.

This pair style does not support the `pair_modify` tail option for adding long-range tail corrections to energy and pressure, since there are no corrections for a potential that goes to 0.0 at the cutoff.

This pair style does not write information to binary restart files, so pair_style and pair_coeff commands must be specified in an input script that reads a restart file.

This pair style can only be used via the `pair` keyword of the run_style respa command. It does not support the inner, middle, outer keywords.
19.265.5 Restrictions

none

19.265.6 Related commands

pair_coeff

19.265.7 Default

none

19.266 pair_style zero command

19.266.1 Syntax

```
pair_style zero cutoff [nocoeff]
```

- zero = style name of this pair style
- cutoff = global cutoff (distance units)
- nocoeff = ignore all pair_coeff parameters (optional)

19.266.2 Examples

```
pair_style zero 10.0
pair_style zero 5.0 nocoeff
pair_coeff * *
pair_coeff 1 2*4 3.0
```

19.266.3 Description

Define a global or per-type cutoff length for the purpose of building a neighbor list and acquiring ghost atoms, but do not compute any pairwise forces or energies.

This can be useful for fixes or computes which require a neighbor list to enumerate pairs of atoms within some cutoff distance, but when pairwise forces are not otherwise needed. Examples are the `fix bond/create`, `compute rdf`, `compute voronoi/atom` commands.

Note that the `comm_modify cutoff` command can be used to insure communication of ghost atoms even when a pair style is not defined, but it will not trigger neighbor list generation.

The optional `nocoeff` flag allows to read data files with a PairCoeff section for any pair style. Similarly, any `pair_coeff` commands will only be checked for the atom type numbers and the rest ignored. In this case, only the global cutoff will be used.
The following coefficients must be defined for each pair of atoms types via the `pair_coeff` command as in the examples above, or in the data file or restart files read by the `read_data` or `read_restart` commands, or by mixing as described below:

- cutoff (distance units)

This coefficient is optional. If not specified, the global cutoff specified in the pair_style command is used. If the pair_style has been specified with the optional `nocoeff` flag, then a cutoff pair coefficient is ignored.

---

### 19.266.4 Mixing, shift, table, tail correction, restart, rRESPA info

The cutoff distance for this pair style can be mixed. The default mix value is geometric. See the “pair_modify” command for details.

This pair style does not support the `pair_modify` shift, table, and tail options.

This pair style writes its information to binary restart files, so pair_style and pair_coeff commands do not need to be specified in an input script that reads a restart file.

This pair style supports the use of the `inner`, `middle`, and `outer` keywords of the `run_style respa` command.

bond_style bpm/rotational myfix 1000 time id1 id2
fix myfix all store/local 1000 3
dump_modify 1 write_header no
20.1.3 Description

The `bpm/rotational` bond style computes forces and torques based on deviations from the initial reference state of the two atoms. The reference state is stored by each bond when it is first computed in the setup of a run. Data is then preserved across run commands and is written to binary restart files such that restarting the system will not reset the reference state of a bond.

Forces include a normal and tangential component. The base normal force has a magnitude of

\[ f_r = k_r (r - r_0) \]

where \( k_r \) is a stiffness and \( r \) is the current distance and \( r_0 \) is the initial distance between the two particles.

A tangential force is applied perpendicular to the normal direction which is proportional to the tangential shear displacement with a stiffness of \( k_s \). This tangential force also induces a torque. In addition, bending and twisting torques are also applied to particles which are proportional to angular bending and twisting displacements with stiffnesses of \( k_b \) and \( k_t \), respectively. Details on the calculations of shear displacements and angular displacement can be found in ref. and (Wang and Mora).

Bonds will break under sufficient stress. A breaking criteria is calculated

\[ B = \max \{0, \frac{f_r}{f_{r,c}} + \frac{|f_s|}{f_{s,c}} + \frac{|\tau_b|}{\tau_{b,c}} + \frac{|\tau_t|}{\tau_{t,c}} \} \]

where \( |f_s| \) is the magnitude of the shear force and \( |\tau_b| \) and \( |\tau_t| \) are the magnitudes of the bending and twisting forces, respectively. The corresponding variables \( f_{r,c} \), \( f_{s,c} \), \( \tau_{b,c} \), and \( \tau_{t,c} \) are critical limits to each force or torque. If \( B \) is ever equal to or exceeds one, the bond will break. This is done by setting by setting its type to 0 such that forces and torques are no longer computed.

After computing the base magnitudes of the forces and torques, they can be optionally multiplied by an extra factor \( w \) to smoothly interpolate forces and torques to zero as the bond breaks. This term is calculated as \( w = (1.0 - B^4) \). This smoothing factor can be added or removed using the `smooth` keyword.

Finally, additional damping forces and torques are applied to the two particles. A force is applied proportional to the difference in the normal velocity of particles using a similar construction as dissipative particle dynamics ((Groot)):

\[ F_D = -\gamma_n w(\hat{r} \cdot \vec{v}) \]

where \( \gamma_n \) is the damping strength, \( \hat{r} \) is the radial normal vector, and \( \vec{v} \) is the velocity difference between the two particles. Similarly, tangential forces are applied to each atom proportional to the relative differences in sliding velocities with a constant prefactor \( \gamma_s \) ((Wang et al.)) along with their associated torques. The rolling and twisting components of the relative angular velocities of the two atoms are also damped by applying torques with prefactors of \( \gamma_r \) and \( \gamma_t \), respectively.

The following coefficients must be defined for each bond type via the `bond_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( k_r \) (force/distance units)
- \( k_s \) (force/distance units)
- \( k_t \) (force*distance/radians units)
- \( k_b \) (force*distance/radians units)
- \( f_{r,c} \) (force units)
- \( f_{s,c} \) (force units)
- \( \tau_{b,c} \) (force*distance units)
• \( \tau_{t,c} \) (force*distance units)
• \( \gamma_n \) (force/velocity units)
• \( \gamma_s \) (force/velocity units)
• \( \gamma_r \) (force*distance/velocity units)
• \( \gamma_t \) (force*distance/velocity units)

By default, pair forces are not calculated between bonded particles. Pair forces can alternatively be overlaid on top of bond forces using the overlay/pair keyword. These settings require specific special_bonds settings described in the restrictions. Further details can be found in the :doc: how to <Howto_BPM> page on BPMs.

If the store/local keyword is used, this fix will track bonds that break during the simulation. Whenever a bond breaks, data is processed and transferred to an internal fix labeled fix_ID. This allows the local data to be accessed by other LAMMPS commands. Following any optional keyword/value arguments, a list of one or more attributes is specified. These include the IDs of the two atoms in the bond. The other attributes for the two atoms include the timestep during which the bond broke and the current/initial center of mass position of the two atoms.

Data is continuously accumulated over intervals of \( N \) timesteps. At the end of each interval, all of the saved accumulated data is deleted to make room for new data. Individual datum may therefore persist anywhere between \( I \) to \( N \) timesteps depending on when they are saved. This data can be accessed using the fix_ID and a dump local command. To ensure all data is output, the dump frequency should correspond to the same interval of \( N \) timesteps. A dump frequency of an integer multiple of \( N \) can be used to regularly output a sample of the accumulated data.

Note that when unbroken bonds are dumped to a file via the dump local command, bonds with type 0 (broken bonds) are not included. The delete_bonds command can also be used to query the status of broken bonds or permanently delete them, e.g.:

```
dele te_bonds all stats
dele te_bonds all bond 0 rem ove
```

## 20.1.4 Restart and other info

This bond style writes the reference state of each bond to binary restart files. Loading a restart file will properly resume bonds.

The single() function of these pair styles returns 0.0 for the energy of a pairwise interaction, since energy is not conserved in these dissipative potentials. It also returns only the normal component of the pairwise interaction force.

The accumulated data is not written to restart files and should be output before a restart file is written to avoid missing data.

The internal fix calculates a local vector or local array depending on the number of input values. The length of the vector or number of rows in the array is the number of recorded, lost interactions. If a single input is specified, a local vector is produced. If two or more inputs are specified, a local array is produced where the number of columns = the number of inputs. The vector or array can be accessed by any command that uses local values from a compute as input. See the Howto output page for an overview of LAMMPS output options.

The vector or array will be floating point values that correspond to the specified attribute.
20.1.5 Restrictions

This bond style can only be used if LAMMPS was built with the BPM package. See the Build package doc page for more info.

By default if pair interactions are to be disabled, this bond style requires setting

```
special_bonds lj 0 1 1 coul 1 1 1
```

and newton must be set to bond off. If the overlay/pair option is used, this bond style alternatively requires setting

```
special_bonds lj/coul 1 1 1
```

The bpm/rotational style requires atom style bpm/sphere.

20.2.3 Description

The *bpm/spring* bond style computes forces and torques based on deviations from the initial reference state of the two atoms. The reference state is stored by each bond when it is first computed in the setup of a run. Data is then preserved across run commands and is written to binary restart files such that restarting the system will not reset the reference state of a bond.

This bond style only applies central-body forces which conserve the translational and rotational degrees of freedom of a bonded set of particles. The force has a magnitude of

\[ F = k(r - r_0)w \]

where \( k \) is a stiffness, \( r \) is the current distance and \( r_0 \) is the initial distance between the two particles, and \( w \) is an optional smoothing factor discussed below. Bonds will break at a strain of \( \epsilon_c \). This is done by setting by setting its type to 0 such that forces are no longer computed.

An additional damping force is applied to the bonded particles. This forces is proportional to the difference in the normal velocity of particles using a similar construction as dissipative particle dynamics ((Groot)):

\[ F_D = -\gamma w(\hat{r} \cdot \vec{v}) \]

where \( \gamma \) is the damping strength, \( \hat{r} \) is the radial normal vector, and \( \vec{v} \) is the velocity difference between the two particles.

The smoothing factor \( w \) can be added or removed using the *smooth* keyword. It is constructed such that forces smoothly go to zero, avoiding discontinuities, as bonds approach the critical strain

\[ w = 1.0 - \left( \frac{r - r_0}{r_0\epsilon_c} \right)^8. \]

The following coefficients must be defined for each bond type via the *bond_coeff* command as in the example above, or in the data file or restart files read by the *read_data* or *read_restart* commands:

- \( k \) (force/distance units)
- \( \epsilon_c \) (unit less)
- \( \gamma \) (force/velocity units)

By default, pair forces are not calculated between bonded particles. Pair forces can alternatively be overlaid on top of bond forces using the *overlay/pair* keyword. These settings require specific *special_bonds* settings described in the restrictions. Further details can be found in the *doc: how to <Howto_BPM>* page on BPMs.
If the `store/local` keyword is used, this fix will track bonds that break during the simulation. Whenever a bond breaks, data is processed and transferred to an internal fix labeled `fix_ID`. This allows the local data to be accessed by other LAMMPS commands. Following any optional keyword/value arguments, a list of one or more attributes is specified. These include the IDs of the two atoms in the bond. The other attributes for the two atoms include the timestep during which the bond broke and the current/initial center of mass position of the two atoms.

Data is continuously accumulated over intervals of \( N \) timesteps. At the end of each interval, all of the saved accumulated data is deleted to make room for new data. Individual datum may therefore persist anywhere between 1 to \( N \) timesteps depending on when they are saved. This data can be accessed using the `fix_ID` and a `dump local` command. To ensure all data is output, the dump frequency should correspond to the same interval of \( N \) timesteps. A dump frequency of an integer multiple of \( N \) can be used to regularly output a sample of the accumulated data.

Note that when unbroken bonds are dumped to a file via the `dump local` command, bonds with type 0 (broken bonds) are not included. The `delete_bonds` command can also be used to query the status of broken bonds or permanently delete them, e.g.:

```
delete_bonds all stats
delete_bonds all bond 0 remove
```

### 20.2.4 Restart and other info

This bond style writes the reference state of each bond to binary restart files. Loading a restart file will properly resume bonds.

The `single()` function of these pair styles returns 0.0 for the energy of a pairwise interaction, since energy is not conserved in these dissipative potentials.

The accumulated data is not written to restart files and should be output before a restart file is written to avoid missing data.

The internal fix calculates a local vector or local array depending on the number of input values. The length of the vector or number of rows in the array is the number of recorded, lost interactions. If a single input is specified, a local vector is produced. If two or more inputs are specified, a local array is produced where the number of columns = the number of inputs. The vector or array can be accessed by any command that uses local values from a compute as input. See the *Howto output* page for an overview of LAMMPS output options.

The vector or array will be floating point values that correspond to the specified attribute.

### 20.2.5 Restrictions

This bond style can only be used if LAMMPS was built with the BPM package. See the *Build package* doc page for more info.

By default if pair interactions are to be disabled, this bond style requires setting

```
special_bonds lj 0 1 1 coul 1 1 1
```

and `newton` must be set to bond off. If the `overlay/pair` option is used, this bond style alternatively requires setting

```
special_bonds lj/coul 1 1 1
```
20.2.6 Related commands

*bond_coeff, pair bpm/spring*

20.2.7 Default

The option defaults are *smooth = yes*

20.3 bond_style class2 command

Accelerator Variants: *class2/omp, class2/kk*

20.3.1 Syntax

```
bond_style class2
```

20.3.2 Examples

```
bond_style class2
bond_coeff 1 1.0 100.0 80.0 80.0
```

20.3.3 Description

The *class2* bond style uses the potential

\[ E = K_2 (r - r_0)^2 + K_3 (r - r_0)^3 + K_4 (r - r_0)^4 \]

where \( r_0 \) is the equilibrium bond distance.

See *(Sun)* for a description of the COMPASS class2 force field.

The following coefficients must be defined for each bond type via the *bond_coeff* command as in the example above, or in the data file or restart files read by the *read_data* or *read_restart* commands:

- \( r_0 \) (distance)
- \( K_2 \) (energy/distance\(^2\))
- \( K_3 \) (energy/distance\(^3\))
- \( K_4 \) (energy/distance\(^4\))

Styles with a *gpu, intel, kk, omp, or opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.
These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 20.3.4 Restrictions

This bond style can only be used if LAMMPS was built with the CLASS2 package. See the Build package page for more info.

### 20.3.5 Related commands

- **bond_coeff**, **delete_bonds**

### 20.3.6 Default

- **none**

### 20.4 bond_style fene command

Accelerator Variants: fene/intel, fene/kk, fene/omp

### 20.5 bond_style fene/nm command

#### 20.5.1 Syntax

```
bond_style fene
bond_style fene/nm
```

#### 20.5.2 Examples

```
bond_style fene
bond_coeff 1 30.0 1.5 1.0 1.0

bond_style fene/nm
bond_coeff 1 2.25344 1.5 1.0 1.12246 2 6
```
20.5.3 Description

The *fene* bond style uses the potential

\[ E = -0.5K R_0^2 \ln \left[ 1 - \left( \frac{r}{R_0} \right)^2 \right] + 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] + \epsilon \]

to define a finite extensible nonlinear elastic (FENE) potential (Kremer), used for bead-spring polymer models. The first term is attractive, the second Lennard-Jones term is repulsive. The first term extends to \( R_0 \), the maximum extent of the bond. The second term is cutoff at \( 2^{\frac{1}{6}}\sigma \), the minimum of the LJ potential.

The *fene/nm* bond style substitutes the standard LJ potential with the generalized LJ potential in the same form as in pair style *nm/cut*. The bond energy is then given by

\[ E = -0.5K r_0^2 \ln \left[ 1 - \left( \frac{r}{r_0} \right)^2 \right] + \frac{E_0}{(n-m)} \left[ m \left( \frac{r_0}{r} \right)^n - n \left( \frac{r_0}{r} \right)^m \right] \]

Similar to the *fene* style, the generalized Lennard-Jones is cut off at the potential minimum, \( r_0 \), to be repulsive only. The following coefficients must be defined for each bond type via the *bond_coeff* command as in the example above, or in the data file or restart files read by the *read_data* or *read_restart* commands:

- \( K \) (energy/distance^2)
- \( R_0 \) (distance)
- \( \epsilon \) (energy)
- \( \sigma \) (distance)

For the *fene/nm* style, the following coefficients are used. Please note, that the standard LJ potential and thus the regular FENE potential is recovered for \((n=12 \ m=6)\) and \( r_0 = 2^{\frac{1}{6}}\sigma \).

- \( K \) (energy/distance^2)
- \( R_0 \) (distance)
- \( E_0 \) (energy)
- \( r_0 \) (distance)
- \( n \) (unitless)
- \( m \) (unitless)

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
20.5.4 Restrictions

The *fene* bond style can only be used if LAMMPS was built with the MOLECULE package; the *fene/nm* bond style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the *Build package* page for more info.

You typically should specify `special_bonds fene` or `special_bonds lj/coul 0 1 1` to use this bond style. LAMMPS will issue a warning if that’s not the case.

20.5.5 Related commands

`bond_coeff`, `delete_bonds`, `pair style lj/cut`, `pair style nm/cut`.

20.5.6 Default

```
none
```

20.6 bond_style fene/expand command

Accelerator Variants: *fene/expand/omp*

20.6.1 Syntax

```
bond_style fene/expand
```

20.6.2 Examples

```
bond_style fene/expand
bond_coeff 1 30.0 1.5 1.0 1.0 0.5
```

20.6.3 Description

The *fene/expand* bond style uses the potential

\[
E = -0.5KR_0^2 \ln \left[ 1 - \left( \frac{r - \Delta}{R_0} \right)^2 \right] + 4\epsilon \left[ \left( \frac{\sigma}{r - \Delta} \right)^{12} - \left( \frac{\sigma}{r - \Delta} \right)^6 \right] + \epsilon
\]

to define a finite extensible nonlinear elastic (FENE) potential (Kremer), used for bead-spring polymer models. The first term is attractive, the second Lennard-Jones term is repulsive.

The *fene/expand* bond style is similar to *fene* except that an extra shift factor of \(\Delta\) (positive or negative) is added to \(r\) to effectively change the bead size of the bonded atoms. The first term now extends to \(R_0 + \Delta\) and the second term is cutoff at \(2^{1/6}\sigma + \Delta\).

The following coefficients must be defined for each bond type via the `bond_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands.
• $K$ (energy/distance^2)
• $R_0$ (distance)
• $\epsilon$ (energy)
• $\sigma$ (distance)
• $\Delta$ (distance)

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script. See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 20.6.4 Restrictions

This bond style can only be used if LAMMPS was built with the MOLECULE package. See the Build package page for more info.

You typically should specify `special_bonds fene` or `special_bonds lj/coul 0 1 1` to use this bond style. LAMMPS will issue a warning if that’s not the case.

### 20.7 bond_style gaussian command

#### 20.7.1 Syntax

```
bond_style gaussian
```
20.7.2 Examples

```plaintext
bond_style gaussian
bond_coeff 1 300.0 2 0.0128 0.375 3.37 0.0730 0.148 3.63
```

20.7.3 Description

The *gaussian* bond style uses the potential:

\[ E = -k_B T \ln \left( \sum_{i=1}^{n} \frac{A_i}{w_i \sqrt{\pi / 2}} \exp \left( -\frac{(r - r_i)^2}{w_i^2} \right) \right) \]

This analytical form is a suitable potential for obtaining mesoscale effective force fields which can reproduce target atomistic distributions (Milano)

The following coefficients must be defined for each bond type via the `bond_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- T temperature at which the potential was derived
- n (integer >=1)
- A1 (-)
- w1 (-)
- r1 (length)
- ...
- An (-)
- wn (-)
- rn (length)

20.7.4 Restrictions

This bond style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the `Build package` doc page for more info.

```

#### 20.10.2 Examples

```
bond_style harmonic/shift
bond_coeff 5 10.0 0.5 1.0
```

#### 20.10.3 Description

The `harmonic/shift` bond style is a shifted harmonic bond that uses the potential

\[
E = \frac{U_{\text{min}}}{(r_0 - r_c)^2} \left[ (r - r_0)^2 - (r_c - r_0)^2 \right]
\]

where \(r_0\) is the equilibrium bond distance, and \(r_c\) the critical distance. The potential is \(-U_{\text{min}}\) at \(r_0\) and zero at \(r_c\). The spring constant is \(k = U_{\text{min}}/[2(r_0 - r_c)^2]\).

The following coefficients must be defined for each bond type via the `bond_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \(U_{\text{min}}\) (energy)
20.10.4 Restrictions

This bond style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the Build package doc page for more info.

```
bond_style harmonic/shift/cut
```

20.11.2 Examples

```
bond_style harmonic/shift/cut
bond_coeff 5 10.0 0.5 1.0
```
20.11.3 Description

The **harmonic/shift/cut** bond style is a shifted harmonic bond that uses the potential

\[
E = \frac{U_{\text{min}}}{(r_0 - r_c)^2} \left[ (r - r_0)^2 - (r_c - r_0)^2 \right]
\]

where \( r_0 \) is the equilibrium bond distance, and \( r_c \) the critical distance. The bond potential is zero for distances \( r > r_c \). The potential is \(-U_{\text{min}}\) at \( r_0 \) and zero at \( r_c \). The spring constant is \( k = U_{\text{min}}/[2(r_0 - r_c)^2] \).

The following coefficients must be defined for each bond type via the **bond_coeff** command as in the example above, or in the data file or restart files read by the **read_data** or **read_restart** commands:

- \( U_{\text{min}} \) (energy)
- \( r_0 \) (distance)
- \( r_c \) (distance)

Styles with a **gpu**, **intel**, **kk**, **omp**, or **opt** suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the **Build package** page for more info.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

20.11.4 Restrictions

This bond style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the **Build package** doc page for more info.

20.11.5 Related commands

**bond_coeff**, **delete_bonds**, **bond_harmonic**, **bond_style harmonic/shift**

20.11.6 Default

none
20.12 bond_style hybrid command

20.12.1 Syntax

```
bond_style hybrid style1 style2 ...
```

- style1, style2 = list of one or more bond styles

20.12.2 Examples

20.12.3 Description

The `hybrid` style enables the use of multiple bond styles in one simulation. A bond style is assigned to each bond type. For example, bonds in a polymer flow (of bond type 1) could be computed with a `fene` potential and bonds in the wall boundary (of bond type 2) could be computed with a `harmonic` potential. The assignment of bond type to style is made via the `bond_coeff` command or in the data file.

In the `bond_coeff` commands, the name of a bond style must be added after the bond type, with the remaining coefficients being those appropriate to that style. In the example above, the 2 `bond_coeff` commands set bonds of bond type 1 to be computed with a `harmonic` potential with coefficients 80.0, 1.2 for $K$, $r_0$. All other bond types (2-N) are computed with a `fene` potential with coefficients 30.0, 1.5, 1.0, 1.0 for $K$, $R_0$, $\epsilon$, $\sigma$.

If bond coefficients are specified in the data file read via the `read_data` command, then the same rule applies. E.g. “harmonic” or “fene” must be added after the bond type, for each line in the “Bond Coeffs” section, e.g.

```
Bond Coeffs
1 harmonic 80.0 1.2
2 fene 30.0 1.5 1.0 1.0
...```

A bond style of `none` with no additional coefficients can be used in place of a bond style, either in a input script `bond_coeff` command or in the data file, if you desire to turn off interactions for specific bond types.

20.12.4 Restrictions

This bond style can only be used if LAMMPS was built with the MOLECULE package. See the `Build package` page for more info.

Unlike other bond styles, the hybrid bond style does not store bond coefficient info for individual sub-styles in a binary restart files. Thus when restarting a simulation from a restart file, you need to re-specify bond_coeff commands.
20.12.5 Related commands

`bond_coeff`, `delete_bonds`

20.12.6 Default

`none`

20.13 `bond_style mm3` command

20.13.1 Syntax

```
bond_style mm3
```

20.13.2 Examples

```
bond_style mm3
bond_coeff 1 100.0 107.0
```

20.13.3 Description

The `mm3` bond style uses the potential that is anharmonic in the bond as defined in (Allinger)

\[
E = K(r - r_0)^2 \left[ 1 - 2.55(r - r_0) + (7/12)(2.55^2)(r - r_0)^2 \right]
\]

where \( r_0 \) is the equilibrium value of the bond, and \( K \) is a prefactor. The anharmonic prefactors have units angstrom\(^{-n}\): -2.55 angstrom\(^{-1}\) and \((7/12)2.55^2\) angstrom\(^{-2}\). The code takes care of the necessary unit conversion for these factors internally. Note that the MM3 papers contains an error in Eq (1): \((7/12)2.55\) should be replaced with \((7/12)2.55^2\).

The following coefficients must be defined for each bond type via the `bond_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- `K` (energy/distance\(^2\))
- `r_0` (distance)

20.13.4 Restrictions

This bond style can only be used if LAMMPS was built with the YAFF package. See the `Build package` doc page for more info.
20.13.5 Related commands

*bond_coeff*

### 20.15 bond_style none command

#### 20.15.1 Syntax

```
bond_style none
```

#### 20.15.2 Examples

```
bond_style none
```

#### 20.15.3 Description

Using a bond style of none means bond forces and energies are not computed, even if pairs of bonded atoms were listed in the data file read by the `read_data` command. See the `bond_style zero` command for a way to calculate bond statistics, but compute no bond interactions.

#### 20.15.4 Restrictions

`none`
20.15.5 Related commands

none
bond_style zero

20.15.6 Default

none

20.16 bond_style nonlinear command

Accelerator Variants: nonlinear/omp

20.16.1 Syntax

bond_style nonlinear

20.16.2 Examples

bond_style nonlinear
bond_coeff 2 100.0 1.1 1.4

20.16.3 Description

The nonlinear bond style uses the potential
\[ E = \frac{\epsilon (r - r_0)^2}{[\lambda^2 - (r - r_0)^2]} \]

to define an anharmonic spring (Rector) of equilibrium length \( r_0 \) and maximum extension \( \lambda \).

The following coefficients must be defined for each bond type via the bond_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- \( \epsilon \) (energy)
- \( r_0 \) (distance)
- \( \lambda \) (distance)

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.
You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch when you invoke LAMMPS, or you can use the `suffix command in your input script. See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

20.16.4 Restrictions

This bond style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the Build package page for more info.

20.16.5 Related commands

`bond_coeff`, `delete_bonds`

20.16.6 Default

(Rector) Rector, Van Swol, Henderson, Molecular Physics, 82, 1009 (1994).

20.17 bond_style oxdna/fene command

20.18 bond_style oxdna2/fene command

20.19 bond_style oxrna2/fene command

20.19.1 Syntax

```
bond_style oxdna/fene
bond_style oxdna2/fene
bond_style oxrna2/fene
```

20.19.2 Examples

```
bond_style oxdna/fene
bond_coeff * 2.0 0.25 0.7525

bond_style oxdna2/fene
bond_coeff * 2.0 0.25 0.7564

bond_style oxrna2/fene
bond_coeff * 2.0 0.25 0.76107
```
20.19.3 Description

The oxdna/fene, oxdna2/fene, and oxrna2/fene bond styles use the potential

\[ E = -\frac{\epsilon}{2} \ln \left[ 1 - \left( \frac{r - r_0}{\Delta} \right)^2 \right] \]

to define a modified finite extensible nonlinear elastic (FENE) potential (Ouldridge) to model the connectivity of the phosphate backbone in the oxDNA/oxRNA force field for coarse-grained modelling of DNA/RNA.

The following coefficients must be defined for the bond type via the bond_coeff command as given in the above example, or in the data file or restart files read by the read_data or read_restart commands:

- \( \epsilon \) (energy)
- \( \Delta \) (distance)
- \( r_0 \) (distance)

**Note:** The oxDNA bond style has to be used together with the corresponding oxDNA pair styles for excluded volume interaction oxdna/excv, stacking oxdna/stk, cross-stacking oxdna/xstk and coaxial stacking interaction oxdna/coaxstk as well as hydrogen-bonding interaction oxdna/hbond (see also documentation of pair_style oxdna/excv). For the oxDNA2 (Snodin) bond style the analogous pair styles oxdna2/excv, oxdna2/stk, oxdna2/xstk, oxdna2/coaxstk, oxdna2/hbond and an additional Debye-Hueckel pair style oxdna2/dh have to be defined. The same applies to the oxRNA2 (Sulc1) styles. The coefficients in the above example have to be kept fixed and cannot be changed without reparameterizing the entire model.

**Note:** This bond style has to be used with the atom_style hybrid bond ellipsoid oxdna (see documentation of atom_style). The atom_style oxdna stores the 3’-to-5’ polarity of the nucleotide strand, which is set through the bond topology in the data file. The first (second) atom in a bond definition is understood to point towards the 3’-end (5’-end) of the strand.

**Warning:** If data files are produced with write_data, then the newton command should be set to newton on or newton off on. Otherwise the data files will not have the same 3’-to-5’ polarity as the initial data file. This limitation does not apply to binary restart files produced with write_restart.

Example input and data files for DNA and RNA duplexes can be found in examples/PACKAGES/cgdna/examples/oxDNA/, oxDNA2/ and oXRNA2/. A simple python setup tool which creates single straight or helical DNA strands, DNA/RNA duplexes or arrays of DNA/RNA duplexes can be found in examples/PACKAGES/cgdna/util/.

Please cite (Henrich) in any publication that uses this implementation. An updated documentation that contains general information on the model, its implementation and performance as well as the structure of the data and input file can be found here.

Please cite also the relevant oxDNA/oxRNA publications. These are (Ouldridge) and (Ouldridge-DPhil) for oxDNA, (Snodin) for oxDNA2, (Sulc1) for oxRNA2 and for sequence-specific hydrogen-bonding and stacking interactions (Sulc2).
20.19.4 Restrictions

This bond style can only be used if LAMMPS was built with the CG-DNA package and the MOLECULE and ASPHERE package. See the Build package page for more info.

20.19.5 Related commands

pair_style oxdna/excv, pair_style oxdna2/excv, pair_style oxrna2/excv, bond_coeff, atom_style oxdna, fix nve/dotc/langevin

20.19.6 Default

20.20 bond_style quartic command

Accelerator Variants: quartic/omp

20.20.1 Syntax

```
bond_style quartic
```

20.20.2 Examples

```
bond_style quartic
bond_coeff 2 1200 -0.55 0.25 1.3 34.6878
```
20.20.3 Description

The *quartic* bond style uses the potential

\[ E = K(r - R_c)^2(r - R_c - B_1)(r - R_c - B_2) + U_0 + 4\epsilon \left[ \left( \frac{\sigma}{r} \right)^{12} - \left( \frac{\sigma}{r} \right)^6 \right] + \epsilon \]

to define a bond that can be broken as the simulation proceeds (e.g. due to a polymer being stretched). The \(\sigma\) and \(\epsilon\) used in the LJ portion of the formula are both set equal to 1.0 by LAMMPS.

The following coefficients must be defined for each bond type via the `bond_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \(K\) (energy/distance^4)
- \(B_1\) (distance)
- \(B_2\) (distance)
- \(R_c\) (distance)
- \(U_0\) (energy)

This potential was constructed to mimic the FENE bond potential for coarse-grained polymer chains. When monomers with \(\sigma = \epsilon = 1.0\) are used, the following choice of parameters gives a quartic potential that looks nearly like the FENE potential:

\[
\begin{align*}
K &= 1200 \\
B_1 &= -0.55 \\
B_2 &= 0.25 \\
R_c &= 1.3 \\
U_0 &= 34.6878
\end{align*}
\]

Different parameters can be specified using the `bond_coeff` command, but you will need to choose them carefully so they form a suitable bond potential.

\(R_c\) is the cutoff length at which the bond potential goes smoothly to a local maximum. If a bond length ever becomes \(> R_c\), LAMMPS “breaks” the bond, which means two things. First, the bond potential is turned off by setting its type to 0, and is no longer computed. Second, a pairwise interaction between the two atoms is turned on, since they are no longer bonded. See the *Howto* page on broken bonds for more information.

LAMMPS does the second task via a computational sleight-of-hand. It subtracts the pairwise interaction as part of the bond computation. When the bond breaks, the subtraction stops. For this to work, the pairwise interaction must always be computed by the `pair_style` command, whether the bond is broken or not. This means that `special_bonds` must be set to 1,1,1, as indicated as a restriction below.

Note that when bonds are dumped to a file via the `dump local` command, bonds with type 0 are not included. The `delete_bonds` command can also be used to query the status of broken bonds or permanently delete them, e.g.:

```
delete_bonds all stats
delete_bonds all bond 0 remove
```

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.
You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 20.20.4 Restrictions

This bond style can only be used if LAMMPS was built with the MOLECULE package. See the Build package page for more info.

The `quartic` style requires that `special_bonds` parameters be set to 1,1,1. Three- and four-body interactions (angle, dihedral, etc) cannot be used with `quartic` bonds.

### 20.20.5 Related commands

`bond_coeff`, `delete_bonds`

### 20.20.6 Default

`none`

### 20.21 bond_style special command

#### 20.21.1 Syntax

```
bond_style special
```

#### 20.21.2 Examples

```
bond_style special
bond_coeff 0.5 0.5
```

#### 20.21.3 Description

The `special` bond style can be used to create conceptual bonds which effectively impose weightings on the pairwise Lennard Jones and/or Coulombic interactions between selected pairs of particles in the system. The form of the pairwise interaction will be whatever is computed by the `pair_style` command defined for the system; this command defines the weightings for its two terms.

This command can thus be useful to apply weightings that cannot be handled by the `special_bonds` command, such as on 1-5 or 1-6 interactions. Or it can be used to add pairwise forces between one or more pairs of atoms that otherwise would not be include in the `pair_style` computation.

The potential for this bond style has the form

\[ E = w_{LJ} E_{LJ} + w_{Coul} E_{Coul} \]
The following coefficients must be defined for each bond type via the `bond_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( w_{LJ} \) weight (0.0 to 1.0) on pairwise Lennard-Jones interactions
- \( w_{Coul} \) weight (0.0 to 1.0) on pairwise Coulombic interactions

Normally this bond style should be used in conjunction with one (or more) other bond styles which compute forces between atoms directly bonded to each other in a molecule. This means the `bond_style hybrid` command should be used with `bond_style special` as one of its sub-styles.

Note that the same as for any other bond style, pairs of bonded atoms must be enumerated in the data file read by the `read_data` command. Thus if this command is used to weight all 1-5 interactions in the system, all the 1-5 pairs of atoms must be listed in the “Bonds” section of the data file.

This bond style imposes strict requirements on settings made with the `special_bonds` command. These requirements ensure that the new bonds created by this style do not create spurious 1-2, 1-3, or 1-4 interactions within the molecular topology.

Specifically 1-2 interactions must have weights of zero, 1-3 interactions must either have weights of unity or `special_bonds angle yes` must be used, and 1-4 interactions must have weights of unity or `special_bonds dihedral yes` must be used.

If this command is used to create bonded interactions between particles that are further apart than usual (e.g. 1-5 or 1-6 interactions), this style may require an increase in the communication cutoff via the `comm_modify cutoff` command. If LAMMPS cannot find a partner atom in a bond, an error will be issued.

### 20.21.4 Restrictions

This bond style can only be used if LAMMPS was built with the MISC package. See the [Build package doc page](#) for more info.

This bond style requires the use of a `pair_style` which computes a pairwise additive interaction and provides the ability to compute interactions for individual pairs of atoms. Manybody potentials are not compatible in general, but also some other pair styles are missing the required functionality and thus will cause an error.

This command is not compatible with long-range Coulombic interactions. If a `kspace_style <kspace_style>` is declared, an error will be issued.

### 20.21.5 Related commands

`bond_coeff`, `special_bonds`

### 20.21.6 Default

none
20.22 bond_style table command

Accelerator Variants: table/omp

20.22.1 Syntax

```
bond_style table style N
```

- style = linear or spline = method of interpolation
- N = use N values in table

20.22.2 Examples

```
bond_style table linear 1000
bond_coeff 1 file.table ENTRY1
```

20.22.3 Description

Style table creates interpolation tables of length $N$ from bond potential and force values listed in a file(s) as a function of bond length. The files are read by the bond_coeff command.

The interpolation tables are created by fitting cubic splines to the file values and interpolating energy and force values at each of $N$ distances. During a simulation, these tables are used to interpolate energy and force values as needed. The interpolation is done in one of 2 styles: linear or spline.

For the linear style, the bond length is used to find 2 surrounding table values from which an energy or force is computed by linear interpolation.

For the spline style, a cubic spline coefficients are computed and stored at each of the $N$ values in the table. The bond length is used to find the appropriate set of coefficients which are used to evaluate a cubic polynomial which computes the energy or force.

The following coefficients must be defined for each bond type via the bond_coeff command as in the example above.

- filename
- keyword

The filename specifies a file containing tabulated energy and force values. The keyword specifies a section of the file. The format of this file is described below.

The format of a tabulated file is as follows (without the parenthesized comments):

```
# Bond potential for harmonic (one or more comment or blank lines)
HAM
N 101 FP 0 0 EQ 0.5

1 0.00 338.0000 1352.0000
2 0.01 324.6152 1324.9600
... 101 1.00 338.0000 -1352.0000
```

The following coefficients:

- $n$ = number of entries
- $k = n - 2$
- $E_k = E_{n-1} - 2E_n + E_{n+1}$
- $M_k = M_{n-1} - 2M_n + M_{n+1}$
- $a_k = E_k - M_k x_k$
- $b_k = M_k - t_k a_k$
- $x_k = \frac{1}{2} (x_{k-1} + x_{k+1})$
- $t_k = \frac{1}{x_{k+1} - x_{k-1}}$
- $F_k = F_{n-1} - 2F_n + F_{n+1}$
- $C_k = C_{n-1} - 2C_n + C_{n+1}$
- $c_k = F_k - C_k x_k$
- $d_k = C_k - t_k c_k$
- $x_k = \frac{1}{2} (x_{k-1} + x_{k+1})$
- $t_k = \frac{1}{x_{k+1} - x_{k-1}}$
A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the bond_coeff command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the N specified in the bond_style table command. Let Ntable = N in the bond_style command, and Nfile = “N” in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the Nfile tabulated values as nodal points. It uses these to interpolate as needed to generate energy and force values at Ntable different points. The resulting tables of length Ntable are then used as described above, when computing energy and force for individual bond lengths. This means that if you want the interpolation tables of length Ntable to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set Ntable = Nfile.

The “FP” parameter is optional. If used, it is followed by two values fplo and fphi, which are the derivatives of the force at the innermost and outermost bond lengths. These values are needed by the spline construction routines. If not specified by the “FP” parameter, they are estimated (less accurately) by the first two and last two force values in the table.

The “EQ” parameter is also optional. If used, it is followed by a the equilibrium bond length, which is used, for example, by the fix shake command. If not used, the equilibrium bond length is to the distance in the table with the lowest potential energy.

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is the bond length r (in distance units), the third value is the energy (in energy units), and the fourth is the force (in force units). The bond lengths must range from a LO value to a HI value, and increase from one line to the next. If the actual bond length is ever smaller than the LO value or larger than the HI value, then the calculation is aborted with an error, so it is advisable to cover the whole range of possible bond lengths.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

20.22.4 Restart, fix_modify, output, run start/stop, minimize info

This bond style writes the settings for the “bond_style table” command to binary restart files, so a bond_style command does not need to specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, bond_coeff commands do need to be specified in the restart input script.
20.22.5 Restrictions

This bond style can only be used if LAMMPS was built with the MOLECULE package. See the Build package page for more info.

20.22.6 Related commands

bond_coeff, delete_bonds

20.22.7 Default

none

20.23 bond_style zero command

20.23.1 Syntax

```
bond_style zero [nocoeff]
```

20.23.2 Examples

```
bond_style zero
bond_style zero nocoeff
bond_coeff * 2.14
```

20.23.3 Description

Using an bond style of zero means bond forces and energies are not computed, but the geometry of bond pairs is still accessible to other commands.

As an example, the compute bond/local command can be used to compute distances for the list of pairs of bond atoms listed in the data file read by the read_data command. If no bond style is defined, this command cannot be used.

The optional nocoeff flag allows to read data files with a BondCoeff section for any bond style. Similarly, any bond_coeff commands will only be checked for the bond type number and the rest ignored.

Note that the bond_coeff command must be used for all bond types. If specified, there can be only one value, which is going to be used to assign an equilibrium distance, e.g. for use with fix shake.
20.23.4 Restrictions

21.1 angle_style charm command

Accelerator Variants: charm/intel, charm/kk, charm/omp

21.1.1 Syntax

```
angle_style charm
```

21.1.2 Examples

```
angle_style charm
angle_coeff 1 300.0 107.0 50.0 3.0
```

21.1.3 Description

The `charm` angle style uses the potential

\[ E = K(\theta - \theta_0)^2 + K_{ub}(r - r_{ub})^2 \]

with an additional Urey_Bradley term based on the distance `r` between the first and third atoms in the angle. \( K, \theta_0, K_{ub}, \text{ and } R_{ub} \) are coefficients defined for each angle type.

See (MacKerell) for a description of the CHARMM force field.

The following coefficients must be defined for each angle type via the `angle_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( K \) (energy)
- \( \theta_0 \) (degrees)
- \( K_{ub} \) (energy/distance^2)
- \( r_{ub} \) (distance)

\( \theta_0 \) is specified in degrees, but LAMMPS converts it to radians internally; hence \( K \) is effectively energy per radian^2.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages.
page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

21.2 angle_style class2 command

Accelerator Variants: class2/kk, class2/omp

21.3 angle_style class2/p6 command

21.3.1 Syntax

```
angle_style class2
```
21.3.2 Examples

```plaintext
angle_style class2
angle_coeff * 75.0
angle_coeff 1 bb 10.5872 1.0119 1.5228
angle_coeff * ba 3.6551 24.895 1.0119 1.5228
```

21.3.3 Description

The `class2` angle style uses the potential

\[
E = E_a + E_{bb} + E_{ba}
\]

\[
E_a = K_2(\theta - \theta_0)^2 + K_3(\theta - \theta_0)^3 + K_4(\theta - \theta_0)^4
\]

\[
E_{bb} = M(r_{ij} - r_1)(r_{jk} - r_2)
\]

\[
E_{ba} = N_1(r_{ij} - r_1)(\theta - \theta_0) + N_2(r_{jk} - r_2)(\theta - \theta_0)
\]

where \(E_a\) is the angle term, \(E_{bb}\) is a bond-bond term, and \(E_{ba}\) is a bond-angle term. \(\theta_0\) is the equilibrium angle and \(r_1\) and \(r_2\) are the equilibrium bond lengths.

See [Sun] for a description of the COMPASS class2 force field.

Coefficients for the \(E_a\), \(E_{bb}\), and \(E_{ba}\) formulas must be defined for each angle type via the `angle_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands.

These are the 4 coefficients for the \(E_a\) formula:

- \(\theta_0\) (degrees)
- \(K_2\) (energy)
- \(K_3\) (energy)
- \(K_4\) (energy)

\(\theta_0\) is specified in degrees, but LAMMPS converts it to radians internally; hence the various \(K\) are effectively energy per radian^2 or radian^3 or radian^4.

For the \(E_{bb}\) formula, each line in an `angle_coeff` command in the input script lists 4 coefficients, the first of which is “bb” to indicate they are BondBond coefficients. In a data file, these coefficients should be listed under a “BondBond Coeffs” heading and you must leave out the “bb”, i.e. only list 3 coefficients after the angle type.

- bb
- \(M\) (energy/distance^2)
- \(r_1\) (distance)
- \(r_2\) (distance)

For the \(E_{ba}\) formula, each line in an `angle_coeff` command in the input script lists 5 coefficients, the first of which is “ba” to indicate they are BondAngle coefficients. In a data file, these coefficients should be listed under a “BondAngle Coeffs” heading and you must leave out the “ba”, i.e. only list 4 coefficients after the angle type.

- ba
- \(N_1\) (energy/distance)
- \(N_2\) (energy/distance)
- \(r_1\) (distance)
- $r_2$ (distance)

The $\theta_0$ value in the $E_{ba}$ formula is not specified, since it is the same value from the $E_a$ formula.

**Note:** It is important that the order of the I, J, K atoms in each angle listed in the Angles section of the data file read by the `read_data` command be consistent with the order of the $r_1$ and $r_2$ BondBond and BondAngle coefficients. This is because the terms in the formulas for $E_{bb}$ and $E_{ba}$ will use the IJ atoms to compute $r_{ij}$ and the JK atoms to compute $r_{jk}$.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script. See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

The class2/p6 angle style uses the class2 potential expanded to sixth order:

$$E_a = K_2 (\theta - \theta_0)^2 + K_3 (\theta - \theta_0)^3 + K_4 (\theta - \theta_0)^4 + K_5 (\theta - \theta_0)^5 + K_6 (\theta - \theta_0)^6$$

In this expanded term 6 coefficients for the $E_a$ formula need to be set:

- $\theta_0$ (degrees)
- $K_2$ (energy)
- $K_3$ (energy)
- $K_4$ (energy)
- $K_5$ (energy)
- $K_6$ (energy)

$\theta_0$ is specified in degrees, but LAMMPS converts it to radians internally; hence the various $K$ are effectively energy per radian^2 or radian^3 or radian^4 or radian^5 or radian^6.

The bond-bond and bond-angle terms remain unchanged.

### 21.3.4 Restrictions

This angle style can only be used if LAMMPS was built with the CLASS2 package. For the class2/p6 style LAMMPS needs to be built with the MOFF package. See the Build package doc page for more info.

21.4 angle_style cosine command

Accelerator Variants: cosine/omp, cosine/kk

21.4.1 Syntax

\texttt{angle_style cosine}

21.4.2 Examples

\begin{verbatim}
angle_style cosine
angle_coeff  * 75.0
\end{verbatim}

21.4.3 Description

The \textit{cosine} angle style uses the potential

\[ E = K[1 + \cos(\theta)] \]

where \( K \) is defined for each angle type.

The following coefficients must be defined for each angle type via the \texttt{angle_coeff} command as in the example above, or in the data file or restart files read by the \texttt{read_data} or \texttt{read_restart} commands:

- \( K \) (energy)

Styles with a \textit{gpu}, \textit{intel}, \textit{kk}, \textit{omp}, or \textit{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \textit{Accelerator packages} page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \texttt{-suffix command-line switch} when you invoke LAMMPS, or you can use the \texttt{suffix} command in your input script.

See the \textit{Accelerator packages} page for more instructions on how to use the accelerated styles effectively.
21.4.4 Restrictions

This angle style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

21.4.5 Related commands

angle_coeff

21.4.6 Default

none

21.5 angle_style cosine/buck6d command

21.5.1 Syntax

```
angle_style cosine/buck6d
```

21.5.2 Examples

```
angle_style cosine/buck6d
angle_coeff 1 cosine/buck6d 1.978350 4 180.000000
```

21.5.3 Description

The `cosine/buck6d` angle style uses the potential

\[ E = K \left[ 1 + \cos(n\theta - \theta_0) \right] \]

where \( K \) is the energy constant, \( n \) is the periodic multiplicity and \( \theta_0 \) is the equilibrium angle.

The coefficients must be defined for each angle type via the `angle_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands in the following order:

- \( K \) (energy)
- \( n \)
- \( \theta_0 \) (degrees)

\( \theta_0 \) is specified in degrees, but LAMMPS converts it to radians internally.

Additional to the cosine term the `cosine/buck6d` angle style computes the short range (vdW) interaction belonging to the `pair_style buck6d` between the end atoms of the angle. For this reason this angle style only works in combination with the `pair_style buck6d` styles and needs the `special_bonds` 1-3 interactions to be weighted 0.0 to prevent double counting.
21.5.4 Restrictions

cosine/buck6d can only be used in combination with the pair_style buck6d style and with a special_bonds 0.0 weighting of 1-3 interactions.

This angle style can only be used if LAMMPS was built with the MOFF package. See the Build package doc page for more info.

21.7 angle_style cosine/periodic command

Accelerator Variants: cosine/periodic/omp

21.7.1 Syntax

```
angle_style cosine/periodic
```

21.7.2 Examples

```
angle_style cosine/periodic
angle_coeff * 75.0 1 6
```
21.7.3 Description

The cosine/periodic angle style uses the following potential, which may be particularly used for organometallic systems where \( n = 4 \) might be used for an octahedral complex and \( n = 3 \) might be used for a trigonal center:

\[
E = \frac{2.0}{n^2} \cdot C \left[ 1 - B(-1)^n \cos(n\theta) \right]
\]

where \( C, B \) and \( n \) are coefficients defined for each angle type.

The following coefficients must be defined for each angle type via the `angle_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( C \) (energy)
- \( B = 1 \) or \(-1\)
- \( n = 1, 2, 3, 4, 5 \) or \( 6 \) for periodicity

Note that the prefactor \( C \) is specified as coefficient and not the overall force constant \( K = \frac{2C}{n^2} \). When \( B = 1 \), it leads to a minimum for the linear geometry. When \( B = -1 \), it leads to a maximum for the linear geometry.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

21.7.4 Restrictions

This angle style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the Build package doc page for more info.

21.8.1 Syntax

```
angle_style cosine/shift
```

21.8.2 Examples

```
angle_style cosine/shift
angle_coeff * 10.0 45.0
```

21.8.3 Description

The `cosine/shift` angle style uses the potential

\[
E = -\frac{U_{\text{min}}}{2} \left[ 1 + \cos(\theta - \theta_0) \right]
\]

where \(\theta_0\) is the equilibrium angle. The potential is bounded between \(-U_{\text{min}}\) and zero. In the neighborhood of the minimum \(E = -U_{\text{min}} + U_{\text{min}}/4(\theta - \theta_0)^2\) hence the spring constant is \(\frac{U_{\text{min}}}{2}\).

The following coefficients must be defined for each angle type via the `angle_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \(U_{\text{min}}\) (energy)
- \(\theta\) (angle)

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

21.8.4 Restrictions

This angle style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the Build package doc page for more info.

21.8.5 Related commands

angle_coeff, angle_style cosine/shift/exp

21.8.6 Default

none

21.9 angle_style cosine/shift/exp command

Accelerator Variants: cosine/shift/exp/omp

21.9.1 Syntax

```
angle_style cosine/shift/exp
```

21.9.2 Examples

```
angle_style cosine/shift/exp
angle_coeff * 10.0 45.0 2.0
```

21.9.3 Description

The `cosine/shift/exp` angle style uses the potential

\[ E = -U_{\text{min}} \frac{e^{-aU(\theta, \theta_0)} - 1}{e^a - 1} \]

with \( U(\theta, \theta_0) = -0.5 \left( 1 + \cos(\theta - \theta_0) \right) \)

where \( U_{\text{min}}, \theta, \) and \( a \) are defined for each angle type.

The potential is bounded between \([-U_{\text{min}}, 0]\) and the minimum is located at the angle \( \theta_0 \). The \( a \) parameter can be both positive or negative and is used to control the spring constant at the equilibrium.

The spring constant is given by \( k = A \exp(A)U_{\text{min}}/[2(\exp(a) - 1)] \). For \( a > 3, \frac{k}{U_{\text{min}}} = \frac{a}{2} \) to better than 5% relative error. For negative values of the \( a \) parameter, the spring constant is essentially zero, and anharmonic terms takes over. The potential is furthermore well behaved in the limit \( a \to 0 \), where it has been implemented to linear order in \( a \) for \( a < 0.001 \). In this limit the potential reduces to the cosine shifted potential.

The following coefficients must be defined for each angle type via the `angle_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( U_{\text{min}} \) (energy)
- \( \theta \) (angle)
• \( A \) (real number)

Styles with a \texttt{gpu}, \texttt{intel}, \texttt{kk}, \texttt{omp}, or \texttt{opt} suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the \texttt{Accelerator packages} page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the \textit{Build package} page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the \texttt{-suffix} command-line switch when you invoke LAMMPS, or you can use the \texttt{suffix} command in your input script.

See the \textit{Accelerator packages} page for more instructions on how to use the accelerated styles effectively.

### 21.10 angle\_style cosine/squared command

Accelerator Variants: \texttt{cosine/squared/omp}

#### 21.10.1 Syntax

```plaintext
angle_style cosine/squared
```

#### 21.10.2 Examples

```plaintext
angle_style cosine/squared
angle_coeff 2° 4 75.0 100.0
```
21.10.3 Description

The cosine/squared angle style uses the potential

\[ E = K[\cos(\theta) - \cos(\theta_0)]^2 \]

, which is commonly used in the DREIDING force field, where \( \theta_0 \) is the equilibrium value of the angle, and \( K \) is a prefactor. Note that the usual 1/2 factor is included in \( K \).

See (Mayo) for a description of the DREIDING force field.

The following coefficients must be defined for each angle type via the angle_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- \( K \) (energy)
- \( \theta_0 \) (degrees)

\( \theta_0 \) is specified in degrees, but LAMMPS converts it to radians internally.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

21.10.4 Restrictions

This angle style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

21.10.5 Related commands

angle_coeff

21.10.6 Default

none

21.11 angle_style cross command

21.11.1 Syntax

```
angle_style cross
```

21.11.2 Examples

```
angle_style cross
angle_coeff 1 200.0 100.0 100.0 1.25 1.25 107.0
```

21.11.3 Description

The `cross` angle style uses a potential that couples the bond stretches of a bend with the angle stretch of that bend:

\[
E = K_{SS}(r_{12} - r_{12,0})(r_{32} - r_{32,0}) + K_{BS0}(r_{12} - r_{12,0})(\theta - \theta_0) + K_{BS1}(r_{32} - r_{32,0})(\theta - \theta_0)
\]

where \( r_{12,0} \) is the rest value of the bond length between atom 1 and 2, \( r_{32,0} \) is the rest value of the bond length between atom 3 and 2, and \( \theta_0 \) is the rest value of the angle. \( K_{SS} \) is the force constant of the bond stretch-bond stretch term and \( K_{BS0} \) and \( K_{BS1} \) are the force constants of the bond stretch-angle stretch terms.

The following coefficients must be defined for each angle type via the `angle_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( K_{SS} \) (energy/distance^2)
- \( K_{BS0} \) (energy/distance)
- \( K_{BS1} \) (energy/distance)
- \( r_{12,0} \) (distance)
- \( r_{32,0} \) (distance)
- \( \theta_0 \) (degrees)

\( \theta_0 \) is specified in degrees, but LAMMPS converts it to radians internally; hence the \( K_{BS0} \) and \( K_{BS1} \) are effectively energy/distance per radian.

21.11.4 Restrictions

This angle style can only be used if LAMMPS was built with the YAFF package. See the `Build package` doc page for more info.
21.11.5 Related commands

angle_coeff

21.12 angle_style dipole command

Accelerator Variants: dipole/omp

21.12.1 Syntax

```
angle_style dipole
```

21.12.2 Examples

```
angle_style dipole
angle_coeff 6 2.1 180.0
```

21.12.3 Description

The dipole angle style is used to control the orientation of a dipolar atom within a molecule (Orsi). Specifically, the dipole angle style restrains the orientation of a point dipole $\vec{\mu}_j$ (embedded in atom $j$) with respect to a reference (bond) vector $\vec{r}_{ij} = \vec{r}_i - \vec{r}_j$, where $i$ is another atom of the same molecule (typically, $i$ and $j$ are also covalently bonded).

It is convenient to define an angle $\gamma$ between the ‘free’ vector $\vec{\mu}_j$ and the reference (bond) vector $\vec{r}_{ij}$:

$$\cos \gamma = \frac{\vec{\mu}_j \cdot \vec{r}_{ij}}{\mu_j r_{ij}}$$

The dipole angle style uses the potential:

$$E = K (\cos \gamma - \cos \gamma_0)^2$$

where $K$ is a rigidity constant and $\gamma_0$ is an equilibrium (reference) angle.

The torque on the dipole can be obtained by differentiating the potential using the ‘chain rule’ as in appendix C.3 of (Allen):

$$\vec{T}_j = 2K (\cos \gamma - \cos \gamma_0) \frac{\mu_j r_{ij}}{\mu_j r_{ij}} \times \vec{\mu}_j$$

Example: if $\gamma_0$ is set to 0 degrees, the torque generated by the potential will tend to align the dipole along the reference direction defined by the (bond) vector $\vec{r}_{ij}$ (in other words, $\vec{\mu}_j$ is restrained to point towards atom $i$).
The dipolar torque $\vec{T}_j$ must be counterbalanced in order to conserve the local angular momentum. This is achieved via an additional force couple generating a torque equivalent to the opposite of $\vec{T}_j$:

$$-\vec{T}_j = r_{ij} \times \vec{F}_i$$
$$\vec{F}_j = -\vec{F}_i$$

where $\vec{F}_i$ and $\vec{F}_j$ are applied on atoms $i$ and $j$, respectively.

The following coefficients must be defined for each angle type via the `angle_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- $K$ (energy)
- $\gamma_0$ (degrees)

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 21.12.4 Restrictions

This angle style can only be used if LAMMPS was built with the DIPOLE package. See the Build package doc page for more info.

**Note:** In the “Angles” section of the data file, the atom ID $j$ defining the direction of the dipole vector to restrain must come before the atom ID of the reference atom $i$. A third atom ID $k$ must also be provided to comply with the requirement of a valid angle definition. This atom ID $k$ should be chosen to be that of an atom bonded to atom $i$ to avoid errors with “lost angle atoms” when running in parallel. Since the LAMMPS code checks for valid angle definitions, cannot use the same atom ID of either $i$ or $j$ (this was allowed and recommended with older LAMMPS versions).

The `newton` command for intramolecular interactions must be “on” (which is the default except when using some accelerator packages).

**Note:** This angle style should NOT be used with fix shake.

angle_style hybrid style1 style2 ...

- style1,style2 = list of one or more angle styles

21.17.2 Examples

angle_style hybrid harmonic cosine
angle_coeff 1 harmonic 80.0 30.0
angle_coeff 2* cosine 50.0

21.17.3 Description

The **hybrid** style enables the use of multiple angle styles in one simulation. An angle style is assigned to each angle type. For example, angles in a polymer flow (of angle type 1) could be computed with a *harmonic* potential and angles in the wall boundary (of angle type 2) could be computed with a *cosine* potential. The assignment of angle type to style is made via the **angle_coeff** command or in the data file.

In the **angle_coeff** commands, the name of an angle style must be added after the angle type, with the remaining coefficients being those appropriate to that style. In the example above, the 2 **angle_coeff** commands set angles of angle type 1 to be computed with a *harmonic* potential with coefficients 80.0, 30.0 for $K$, $\theta_0$. All other angle types ($2 - N$) are computed with a *cosine* potential with coefficient 50.0 for $K$.

If angle coefficients are specified in the data file read via the **read_data** command, then the same rule applies. E.g. “harmonic” or “cosine”, must be added after the angle type, for each line in the “Angle Coefs” section, e.g.

Angle Coefs

1 harmonic 80.0 30.0
2 cosine 50.0
...

If **class2** is one of the angle hybrid styles, the same rule holds for specifying additional BondBond (and BondAngle) coefficients either via the input script or in the data file. I.e. **class2** must be added to each line after the angle type. For lines in the BondBond (or BondAngle) section of the data file for angle types that are not **class2**, you must use an angle style of *skip* as a placeholder, e.g.
BondBond Coeffs

1 skip
2 class2 3.6512 1.0119 1.0119
...

Note that it is not necessary to use the angle style skip in the input script, since BondBond (or BondAngle) coefficients need not be specified at all for angle types that are not class2.

An angle style of none with no additional coefficients can be used in place of an angle style, either in a input script angle_coeff command or in the data file, if you desire to turn off interactions for specific angle types.

21.17.4 Restrictions

This angle style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

Unlike other angle styles, the hybrid angle style does not store angle coefficient info for individual sub-styles in a binary restart files. Thus when restarting a simulation from a restart file, you need to re-specify angle_coeff commands.

21.17.5 Related commands

angle_coeff

21.17.6 Default

none

21.18 angle_style mm3 command

21.18.1 Syntax

angle_style mm3

21.18.2 Examples

angle_style mm3
angle_coeff 1 100.0 107.0
21.18.3 Description

The mm3 angle style uses the potential that is anharmonic in the angle as defined in (Allinger)

\[ E = K(\theta - \theta_0)^2 \left[ 1 - 0.014(\theta - \theta_0) + 5.6(10)^{-5}(\theta - \theta_0)^2 - 7.0(10)^{-7}(\theta - \theta_0)^3 + 9(10)^{-10}(\theta - \theta_0)^4 \right] \]

where \( \theta_0 \) is the equilibrium value of the angle, and \( K \) is a prefactor. The anharmonic prefactors have units \( \text{deg}^{-n} \), for example \(-0.014 \text{ deg}^{-1}, 5.6 \cdot 10^{-5} \text{ deg}^{-2}, \ldots \)

The following coefficients must be defined for each angle type via the angle_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- \( K \) (energy)
- \( \theta_0 \) (degrees)

\( \theta_0 \) is specified in degrees, but LAMMPS converts it to radians internally; hence \( K \) is effectively energy per radian^2.

21.18.4 Restrictions

This angle style can only be used if LAMMPS was built with the YAFF package. See the Build package doc page for more info.

21.18.5 Related commands

angle_coeff

21.18.6 Default

none

21.19 angle_style none command

21.19.1 Syntax

angle_style none

21.19.2 Examples

angle_style none
21.19.3 Description

Using an angle style of none means angle forces and energies are not computed, even if triplets of angle atoms were listed in the data file read by the \textit{read\_data} command. See the \textit{angle\_style zero} command for a way to calculate angle statistics, but compute no angle interactions.

21.19.4 Restrictions

none

21.19.5 Related commands

\textit{angle\_style zero}

21.19.6 Default

none

21.20 \textit{angle\_style quartic} command

Accelerator Variants: \textit{quartic/omp}

21.20.1 Syntax

\begin{verbatim}
angle_style quartic
\end{verbatim}

21.20.2 Examples

\begin{verbatim}
angle_style quartic
angle_coeff 1 129.1948 56.8726 -25.9442 -14.2221
\end{verbatim}

21.20.3 Description

The \textit{quartic} angle style uses the potential

\[ E = K_2(\theta - \theta_0)^2 + K_3(\theta - \theta_0)^3 + K_4(\theta - \theta_0)^4 \]

where \( \theta_0 \) is the equilibrium value of the angle, and \( K \) is a prefactor. Note that the usual 1/2 factor is included in \( K \).

The following coefficients must be defined for each angle type via the \textit{angle\_coeff} command as in the example above, or in the data file or restart files read by the \textit{read\_data} or \textit{read\_restart} commands:

\begin{itemize}
  \item \( \theta_0 \) (degrees)
  \item \( K_2 \) (energy)
  \item \( K_3 \) (energy)
\end{itemize}
• $K_4$ (energy)

$\theta_0$ is specified in degrees, but LAMMPS converts it to radians internally; hence the various $K$ are effectively energy per radian$^2$ or radian$^3$ or radian$^4$.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 21.20.4 Restrictions

This angle style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the Build package doc page for more info.

### 21.20.5 Related commands

`angle_coeff`

### 21.20.6 Default

`none`

### 21.21 angle_style sdk command

Accelerator Variants: `sdk/omp`

#### 21.21.1 Syntax

```plaintext
angle_style  sdk
angle_style  sdk/omp
```
21.21.2 Examples

<table>
<thead>
<tr>
<th>angle_style</th>
<th>sdk</th>
</tr>
</thead>
<tbody>
<tr>
<td>angle_coeff</td>
<td>1 300.0</td>
</tr>
<tr>
<td></td>
<td>107.0</td>
</tr>
</tbody>
</table>

21.21.3 Description

The *sdk* angle style is a combination of the harmonic angle potential,

\[ E = K (\theta - \theta_0)^2 \]

where \( \theta_0 \) is the equilibrium value of the angle and \( K \) a prefactor, with the repulsive part of the non-bonded \( lj/sdk \) pair style between the atoms 1 and 3. This angle potential is intended for coarse grained MD simulations with the CMM parameterization using the pair_style \( lj/sdk \). Relative to the pair_style \( lj/sdk \), however, the energy is shifted by \( \epsilon \), to avoid sudden jumps. Note that the usual \( 1/2 \) factor is included in \( K \).

The following coefficients must be defined for each angle type via the `angle_coeff` command as in the example above:

- \( K \) (energy)
- \( \theta_0 \) (degrees)

\( \theta_0 \) is specified in degrees, but LAMMPS converts it to radians internally; hence \( K \) is effectively energy per radian^2.

The required \( lj/sdk \) parameters are extracted automatically from the pair_style.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script. See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

21.21.4 Restrictions

This angle style can only be used if LAMMPS was built with the CG-SDK package. See the Build package doc page for more info.

21.21.6 Default

none

21.22 angle_style table command

Accelerator Variants: table/omp

21.22.1 Syntax

angle_style table style N

• style = linear or spline = method of interpolation
• N = use N values in table

21.22.2 Examples

angle_style table linear 1000
angle_coeff 3 file.table ENTRY1

21.22.3 Description

Style table creates interpolation tables of length $N$ from angle potential and derivative values listed in a file(s) as a function of angle. The files are read by the angle_coeff command.

The interpolation tables are created by fitting cubic splines to the file values and interpolating energy and derivative values at each of $N$ angles. During a simulation, these tables are used to interpolate energy and force values on individual atoms as needed. The interpolation is done in one of 2 styles: linear or spline.

For the linear style, the angle is used to find 2 surrounding table values from which an energy or its derivative is computed by linear interpolation.

For the spline style, a cubic spline coefficients are computed and stored at each of the $N$ values in the table. The angle is used to find the appropriate set of coefficients which are used to evaluate a cubic polynomial which computes the energy or derivative.

The following coefficients must be defined for each angle type via the angle_coeff command as in the example above.

• filename
• keyword

The filename specifies a file containing tabulated energy and derivative values. The keyword specifies a section of the file. The format of this file is described below.

The format of a tabulated file is as follows (without the parenthesized comments):
# Angle potential for harmonic (one or more comment or blank lines)

HAM

N 181 FP 0 0 EQ 90.0

1 0.0 200.5 2.5
2 1.0 198.0 2.5
...
181 180.0 0.0 0.0

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the angle_coeff command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the N specified in the angle_style table command. Let Ntable = N in the angle_style command, and Nfile = “N” in the tabulated file. What LAMMPS does is a preliminary interpolation by creating splines using the Nfile tabulated values as nodal points. It uses these to interpolate as needed to generate energy and derivative values at Ntable different points. The resulting tables of length Ntable are then used as described above, when computing energy and force for individual angles and their atoms. This means that if you want the interpolation tables of length Ntable to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set Ntable = Nfile.

The “FP” parameter is optional. If used, it is followed by two values fplo and fphi, which are the second derivatives at the innermost and outermost angle settings. These values are needed by the spline construction routines. If not specified by the “FP” parameter, they are estimated (less accurately) by the first two and last two derivative values in the table.

The “EQ” parameter is also optional. If used, it is followed by a the equilibrium angle value, which is used, for example, by the fix shake command. If not used, the equilibrium angle is set to 180.0.

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is the angle value (in degrees), the third value is the energy (in energy units), and the fourth is -dE/d(theta) (also in energy units). The third term is the energy of the 3-atom configuration for the specified angle. The last term is the derivative of the energy with respect to the angle (in degrees, not radians). Thus the units of the last term are still energy, not force. The angle values must increase from one line to the next. The angle values must also begin with 0.0 and end with 180.0, i.e. span the full range of possible angles.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

---

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
21.22.4 Restart, fix_modify, output, run start/stop, minimize info

This angle style writes the settings for the “angle_style table” command to binary restart files, so a angle_style command does not need to specified in an input script that reads a restart file. However, the coefficient information is not stored in the restart file, since it is tabulated in the potential files. Thus, angle_coeff commands do need to be specified in the restart input script.

21.22.5 Restrictions

This angle style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

21.22.6 Related commands

angle_coeff

21.22.7 Default

none

21.23 angle_style zero command

21.23.1 Syntax

```
angle_style zero *nocoeff*
```

21.23.2 Examples

```
angle_style zero
angle_style zero nocoeff
angle_coeff *
angle_coeff = 120.0
```

21.23.3 Description

Using an angle style of zero means angle forces and energies are not computed, but the geometry of angle triplets is still accessible to other commands.

As an example, the compute angle/local command can be used to compute the theta values for the list of triplets of angle atoms listed in the data file read by the read_data command. If no angle style is defined, this command cannot be used.

The optional nocoeff flag allows to read data files with AngleCoeff section for any angle style. Similarly, any angle_coeff commands will only be checked for the angle type number and the rest ignored.

Note that the angle_coeff command must be used for all angle types. If specified, there can be only one value, which is going to be used to assign an equilibrium angle, e.g. for use with fix shake.
21.23.4 Restrictions

none

21.23.5 Related commands

angle_style none

21.23.6 Default

22.1 dihedral_style charmm command

Accelerator Variants: charmm/intel, charmm/kk, charmm/omp

22.2 dihedral_style charmmfsw command

22.2.1 Syntax

```
dihedral_style style
```

- style = charmm or charmmfsw

22.2.2 Examples

```
dihedral_style charmm

dihedral_style charmmfsw

dihedral_coeff 1 0.2 1 180 1.0

dihedral_coeff 2 1.8 1 0 1.0

dihedral_coeff 1 3.1 2 180 0.5
```

22.2.3 Description

The charmm and charmmfsw dihedral styles use the potential

\[
E = K[1 + \cos(n\phi - d)]
\]

See (MacKerell) for a description of the CHARMM force field. This dihedral style can also be used for the AMBER force field (see comment on weighting factors below). See (Cornell) for a description of the AMBER force field.

**Note:** The newer charmmfsw style was released in March 2017. We recommend it be used instead of the older charmm style when running a simulation with the CHARMM force field, either with long-range Coulombs or a Coulombic cutoff, via the pair_style lj/charmmfsw/coul/long and pair_style lj/charmmfsw/coul/charmmfsh commands respectively. Otherwise the older charmm style is fine to use. See the discussion below and more details on the pair_style charmm doc page.
The following coefficients must be defined for each dihedral type via the `dihedral_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- $K$ (energy)
- $n$ (integer $\geq 0$)
- $d$ (integer value of degrees)
- weighting factor (1.0, 0.5, or 0.0)

The weighting factor is required to correct for double counting pairwise non-bonded Lennard-Jones interactions in cyclic systems or when using the CHARMM dihedral style with non-CHARMM force fields. With the CHARMM dihedral style, interactions between the first and fourth atoms in a dihedral are skipped during the normal non-bonded force computation and instead evaluated as part of the dihedral using special epsilon and sigma values specified with the `pair_coeff` command of pair styles that contain “lj/charmm” (e.g. `pair_style lj/charmm/coul/long`.) In 6-membered rings, the same 1-4 interaction would be computed twice (once for the clockwise 1-4 pair in dihedral 1-2-3-4 and once in the counterclockwise dihedral 1-6-5-4) and thus the weighting factor has to be 0.5 in this case. In 4-membered or 5-membered rings, the 1-4 dihedral also is counted as a 1-2 or 1-3 interaction when going around the ring in the opposite direction and thus the weighting factor is 0.0, as the 1-2 and 1-3 exclusions take precedence.

Note that this dihedral weighting factor is unrelated to the scaling factor specified by the `special_bonds` command which applies to all 1-4 interactions in the system. For CHARMM force fields, the `special_bonds` 1-4 interaction scaling factor should be set to 0.0. Since the corresponding 1-4 non-bonded interactions are computed with the dihedral. This means that if any of the weighting factors defined as dihedral coefficients (fourth coeff above) are non-zero, then you must use a pair style with “lj/charmm” and set the `special_bonds` 1-4 scaling factor to 0.0 (which is the default). Otherwise 1-4 non-bonded interactions in dihedrals will be computed twice.

For simulations using the CHARMM force field with a Coulombic cutoff, the difference between the `charmm` and `charmmfsw` styles is in the computation of the 1-4 non-bond interactions, though only if the distance between the two atoms is within the switching region of the pairwise potential defined by the corresponding CHARMM pair style, i.e. within the outer cutoff specified for the pair style. The `charmmfsw` style should only be used when using the corresponding `pair_style lj/charmmfsw/coul/charmmfsw` or `pair_style lj/charmmfsw/coul/long` commands. Use the `charmm` style with the older `pair_style` commands that have just “charmm” in their style name. See the discussion on the CHARMM `pair_style` page for details.

Note that for AMBER force fields, which use pair styles with “lj/cut”, the `special_bonds` 1-4 scaling factor should be set to the AMBER defaults (1/2 and 5/6) and all the dihedral weighting factors (fourth coeff above) must be set to 0.0. In this case, you can use any pair style you wish, since the dihedral does not need any Lennard-Jones parameter information and will not compute any 1-4 non-bonded interactions. Likewise the `charmm` or `charmmfsw` styles are identical in this case since no 1-4 non-bonded interactions are computed.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.
22.2.4 Restrictions

When using run_style respa, these dihedral styles must be assigned to the same r-RESPA level as pair or outer. When used in combination with CHARMM pair styles, the 1-4 special_bonds scaling factors must be set to 0.0. Otherwise non-bonded contributions for these 1-4 pairs will be computed multiple times.

These dihedral styles can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

22.3. dihedral_style class2 command
22.3.3 Description

The class2 dihedral style uses the potential

\[ E = E_d + E_{mbt} + E_{ebt} + E_{aat} + E_{bb13} \]

\[ E_d = \sum_{n=1}^{3} K_n [1 - \cos(n\phi - \phi_n)] \]

\[ E_{mbt} = (r_{jk} - r_2) [A_1 \cos(\phi) + A_2 \cos(2\phi) + A_3 \cos(3\phi)] \]

\[ E_{ebt} = (r_{ij} - r_1) [B_1 \cos(\phi) + B_2 \cos(2\phi) + B_3 \cos(3\phi)] +
            (r_{kl} - r_3) [C_1 \cos(\phi) + C_2 \cos(2\phi) + C_3 \cos(3\phi)] \]

\[ E_{aat} = (\theta_{ijk} - \theta_1) [D_1 \cos(\phi) + D_2 \cos(2\phi) + D_3 \cos(3\phi)] +
           (\theta_{jkl} - \theta_2) [E_1 \cos(\phi) + E_2 \cos(2\phi) + E_3 \cos(3\phi)] \]

\[ E_{aat} = M (\theta_{ijk} - \theta_1)(\theta_{jkl} - \theta_2) \cos(\phi) \]

\[ E_{bb13} = N (r_{ij} - r_1)(r_{kl} - r_3) \]

where \( E_d \) is the dihedral term, \( E_{mbt} \) is a middle-bond-torsion term, \( E_{ebt} \) is an end-bond-torsion term, \( E_{aat} \) is an angle-torsion term, \( E_{aat} \) is an angle-angle-torsion term, and \( E_{bb13} \) is a bond-bond-13 term.

\( \theta_1 \) and \( \theta_2 \) are equilibrium angles and \( r_1, r_2, \) and \( r_3 \) are equilibrium bond lengths.

See \( \text{(Sun)} \) for a description of the COMPASS class2 force field.

Coefficients for the \( E_d, E_{mbt}, E_{ebt}, E_{aat}, \) and \( E_{bb13} \) formulas must be defined for each dihedral type via the \textit{dihedral_coeff} command as in the example above, or in the data file or restart files read by the \textit{read_data} or \textit{read_restart} commands.

These are the 6 coefficients for the \( E_d \) formula:

- \( K_1 \) (energy)
- \( \phi_1 \) (degrees)
- \( K_2 \) (energy)
- \( \phi_2 \) (degrees)
- \( K_3 \) (energy)
- \( \phi_3 \) (degrees)

For the \( E_{mbt} \) formula, each line in a \textit{dihedral_coeff} command in the input script lists 5 coefficients, the first of which is \textit{mbt} to indicate they are MiddleBondTorsion coefficients. In a data file, these coefficients should be listed under a \textit{MiddleBondTorsion Coeffs} heading and you must leave out the \textit{mbt}, i.e. only list 4 coefficients after the dihedral type.

- \textit{mbt}
- \( A_1 \) (energy/distance)
- \( A_2 \) (energy/distance)
- \( A_3 \) (energy/distance)
- \( r_2 \) (distance)

For the \( E_{ebt} \) formula, each line in a \textit{dihedral_coeff} command in the input script lists 9 coefficients, the first of which is \textit{ebt} to indicate they are EndBondTorsion coefficients. In a data file, these coefficients should be listed under a \textit{EndBondTorsion Coeffs} heading and you must leave out the \textit{ebt}, i.e. only list 8 coefficients after the dihedral type.

- \textit{ebt}
- \( B_1 \) (energy/distance)
• $B_2$ (energy/distance)
• $B_3$ (energy/distance)
• $C_1$ (energy/distance)
• $C_2$ (energy/distance)
• $r_1$ (distance)
• $r_3$ (distance)

For the $E_{at}$ formula, each line in a `dihedral_coeff` command in the input script lists 9 coefficients, the first of which is `at` to indicate they are AngleTorsion coefficients. In a data file, these coefficients should be listed under an `AngleTorsion Coeffs` heading and you must leave out the `at`, i.e. only list 8 coefficients after the dihedral type.

• `at`
• $D_1$ (energy)
• $D_2$ (energy)
• $D_3$ (energy)
• $E_1$ (energy)
• $E_2$ (energy)
• $E_3$ (energy)
• $\theta_1$ (degrees)
• $\theta_2$ (degrees)

$\theta_1$ and $\theta_2$ are specified in degrees, but LAMMPS converts them to radians internally; hence the various $D$ and $E$ are effectively energy per radian.

For the $E_{aat}$ formula, each line in a `dihedral_coeff` command in the input script lists 4 coefficients, the first of which is `aat` to indicate they are AngleAngleTorsion coefficients. In a data file, these coefficients should be listed under an `AngleAngleTorsion Coeffs` heading and you must leave out the `aat`, i.e. only list 3 coefficients after the dihedral type.

• `aat`
• $M$ (energy)
• $\theta_1$ (degrees)
• $\theta_2$ (degrees)

$\theta_1$ and $\theta_2$ are specified in degrees, but LAMMPS converts them to radians internally; hence $M$ is effectively energy per radian$^2$.

For the $E_{bb13}$ formula, each line in a `dihedral_coeff` command in the input script lists 4 coefficients, the first of which is `bb13` to indicate they are BondBond13 coefficients. In a data file, these coefficients should be listed under a `BondBond13 Coeffs` heading and you must leave out the `bb13`, i.e. only list 3 coefficients after the dihedral type.

• `bb13`
• $N$ (energy/distance$^2$)
• $r_1$ (distance)
• $r_3$ (distance)
Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 22.3.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the CLASS2 package. See the Build package doc page for more info.

### 22.3.5 Related commands

### 22.4 dihedral_style cosine/shift/exp command

Accelerator Variants: `cosine/shift/exp/omp`

#### 22.4.1 Syntax

```
dihedral_style cosine/shift/exp
```

#### 22.4.2 Examples

```
dihedral_style cosine/shift/exp
dihedral_coeff 1 10.0 45.0 2.0
```
22.4.3 Description

The cosine/shift/exp dihedral style uses the potential

\[ E = -U_{\text{min}} \frac{e^{-aU(\theta,\theta_0)} - 1}{e^a - 1} \quad \text{with} \quad U(\theta,\theta_0) = -0.5 \left(1 + \cos(\theta - \theta_0)\right) \]

where \( U_{\text{min}}, \theta, \) and \( a \) are defined for each dihedral type.

The potential is bounded between \([-U_{\text{min}} : 0]\) and the minimum is located at the angle \( \theta_0 \). The a parameter can be both positive or negative and is used to control the spring constant at the equilibrium.

The spring constant is given by \( k = a e^a \frac{U_{\text{min}}^2}{2(e^a - 1)} \). For \( a > 3 \) and \( k \frac{U_{\text{min}}}{k} \) to better than 5% relative error. For negative values of the a parameter, the spring constant is essentially zero, and anharmonic terms takes over. The potential is furthermore well behaved in the limit \( a \to 0 \), where it has been implemented to linear order in \( a \) for \( a < 0.001 \).

The following coefficients must be defined for each dihedral type via the `dihedral_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( U_{\text{min}} \) (energy)
- \( \theta \) (angle)
- \( a \) (real number)

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

22.4.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

22.4.5 Related commands

```
dihedral_style fourier
```

22.5.2 Examples

```
dihedral_style fourier
dihedral_coeff 1 3 -0.846200 3 0.0 7.578800 1 0 0.138000 2 -180.0
```

22.5.3 Description

The `fourier` dihedral style uses the potential:

\[
E = \sum_{i=1,m} K_i[1.0 + \cos(n_i \phi - d_i)]
\]

The following coefficients must be defined for each dihedral type via the `dihedral_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \(m\) (integer >=1)
- \(K_1\) (energy)
- \(n_1\) (integer >= 0)
- \(d_1\) (degrees)
- […]
- \(K_m\) (energy)
- \(n_m\) (integer >= 0)
- \(d_m\) (degrees)

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Accelerator packages` page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.
See the *Accelerator packages* page for more instructions on how to use the accelerated styles effectively.

### 22.5.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the *Build package* doc page for more info.

### 22.6 dihedral_style harmonic command

Accelerator Variants: *harmonic/intel, harmonic/kk, harmonic/omp*

#### 22.6.1 Syntax

```
dihedral_style harmonic
```

#### 22.6.2 Examples

```
dihedral_style harmonic
dihedral_coeff 1 80.0 1 2
```

#### 22.6.3 Description

The *harmonic* dihedral style uses the potential

\[ E = K[1 + d \cos(n\phi)] \]

The following coefficients must be defined for each dihedral type via the *dihedral_coeff* command as in the example above, or in the data file or restart files read by the *read_data* or *read_restart* commands:

- \( K \) (energy)
- \( d \) (+1 or -1)
- \( n \) (integer >= 0)

**Note:** Here are important points to take note of when defining LAMMPS dihedral coefficients for the harmonic style, so that they are compatible with how harmonic dihedrals are defined by other force fields:
• The LAMMPS convention is that the trans position = 180 degrees, while in some force fields trans = 0 degrees.
• Some force fields reverse the sign convention on $d$.
• Some force fields let $n$ be positive or negative which corresponds to $d = 1$ or $d = -1$ for the harmonic style.

Styles with a $gpu$, $intel$, $kk$, $omp$, or $opt$ suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

22.6.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

22.7 dihedral_style helix command

Accelerator Variants: helix/omp

22.7.1 Syntax

| dihedral_style helix |
22.7.2 Examples

```plaintext
dihedral_style helix
dihedral_coeff 1 80.0 100.0 40.0
```

22.7.3 Description

The `helix` dihedral style uses the potential

\[
E = A[1 - \cos(\theta)] + B[1 + \cos(3\theta)] + C[1 + \cos(\theta + \frac{\pi}{4})]
\]

This coarse-grain dihedral potential is described in (Guo). For dihedral angles in the helical region, the energy function is represented by a standard potential consisting of three minima, one corresponding to the trans (t) state and the other to gauche states (g+ and g-). The paper describes how the \( A \), \( B \) and, \( C \) parameters are chosen so as to balance secondary (largely driven by local interactions) and tertiary structure (driven by long-range interactions).

The following coefficients must be defined for each dihedral type via the `dihedral_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( A \) (energy)
- \( B \) (energy)
- \( C \) (energy)

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP, and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

22.8 dihedral_style hybrid command

22.8.1 Syntax

```
dihedral_style hybrid style1 style2 ...
```

- style1,style2 = list of one or more dihedral styles

22.8.2 Examples

```
dihedral_style hybrid harmonic helix
dihedral_coeff 1 harmonic 6.0 1 3
dihedral_coeff 2* helix 10 10 10
```

22.8.3 Description

The hybrid style enables the use of multiple dihedral styles in one simulation. An dihedral style is assigned to each dihedral type. For example, dihedrals in a polymer flow (of dihedral type 1) could be computed with a harmonic potential and dihedrals in the wall boundary (of dihedral type 2) could be computed with a helix potential. The assignment of dihedral type to style is made via the `dihedral_coeff` command or in the data file.

In the dihedral_coeff commands, the name of a dihedral style must be added after the dihedral type, with the remaining coefficients being those appropriate to that style. In the example above, the 2 dihedral_coeff commands set dihedrals of dihedral type 1 to be computed with a harmonic potential with coefficients 6.0, 1, 3 for K, d, n. All other dihedral types (2-N) are computed with a helix potential with coefficients 10, 10, 10 for A, B, C.

If dihedral coefficients are specified in the data file read via the `read_data` command, then the same rule applies. E.g. “harmonic” or “helix”, must be added after the dihedral type, for each line in the “Dihedral Coeffs” section, e.g.

```
Dihedral Coeffs

1 harmonic 6.0 1 3
2 helix 10 10 10
...
```

If class2 is one of the dihedral hybrid styles, the same rule holds for specifying additional AngleTorsion (and EndBondTorsion, etc) coefficients either via the input script or in the data file. I.e. class2 must be added to each line after the dihedral type. For lines in the AngleTorsion (or EndBondTorsion, etc) Coeffs section of the data file for dihedral types that are not class2, you must use an dihedral style of skip as a placeholder, e.g.
AngleTorsion Coeffs

1 skip
2 class2 1.0 1.0 1.0 3.0 3.0 3.0 30.0 50.0
...

Note that it is not necessary to use the dihedral style *skip* in the input script, since AngleTorsion (or EndBondTorsion, etc) coefficients need not be specified at all for dihedral types that are not *class2*.

A dihedral style of *none* with no additional coefficients can be used in place of a dihedral style, either in a input script dihedral_coeff command or in the data file, if you desire to turn off interactions for specific dihedral types.

### 22.8.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the MOLECULE package. See the *Build package* doc page for more info.

Unlike other dihedral styles, the hybrid dihedral style does not store dihedral coefficient info for individual sub-styles in a *binary restart files*. Thus when restarting a simulation from a restart file, you need to re-specify dihedral_coeff commands.

### 22.8.5 Related commands

22.12.1 Syntax

dihedral_style opls

22.12.2 Examples

| dihedral_style opls | dihedral_coeff 1 1.740 -0.157 0.279 0.00 # CT-CT-CT-CT | dihedral_coeff 2 0.000 0.000 0.366 0.000 # CT-CT-CT-HC | dihedral_coeff 3 0.000 0.000 0.318 0.000 # HC-CT-CT-HC |

22.12.3 Description

The opls dihedral style uses the potential

\[
E = \frac{1}{2}K_1[1 + \cos(\phi)] + \frac{1}{2}K_2[1 - \cos(2\phi)] + \frac{1}{2}K_3[1 + \cos(3\phi)] + \frac{1}{2}K_4[1 - \cos(4\phi)]
\]

Note that the usual 1/2 factor is not included in the K values.

This dihedral potential is used in the OPLS force field and is described in (Watkins).

The following coefficients must be defined for each dihedral type via the dihedral_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- \(K_1\) (energy)
- \(K_2\) (energy)
- \(K_3\) (energy)
- \(K_4\) (energy)

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. dihedral_style quadratic
```

#### 22.13.2 Examples

```
dihedral_style quadratic
dihedral_coeff 100.0 80.0
```

#### 22.13.3 Description

The *quadratic* dihedral style uses the potential:

\[
E = K(\phi - \phi_0)^2
\]

This dihedral potential can be used to keep a dihedral in a predefined value (cis=zero, right-hand convention is used). The following coefficients must be defined for each dihedral type via the *dihedral_coeff* command as in the example above, or in the data file or restart files read by the *read_data* or *read_restart* commands.
• $K$ (energy)
• $\phi_0$ (degrees)

$\phi_0$ is specified in degrees, but LAMMPS converts it to radians internally; hence $K$ is effectively energy per radian^2.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 22.13.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the Build package doc page for more info.

### 22.13.5 Related commands

`dihedral_coeff`

### 22.13.6 Default

none

### 22.14 dihedral_style spherical command

#### 22.14.1 Syntax

```
dihedral_style spherical
```

#### 22.14.2 Examples

```
dihedral_coeff 1 1 286.1 1 124 1 1 90.0 0 1 90.0 0
```

```
dihedral_coeff 1 3 69.3 1 93.9 1 1 90 0 1 90 0 &
  49.1 0 0.00 0 1 74.4 1 0 0.00 0 &
  25.2 0 0.00 0 0 0.00 0 1 48.1 1
```
22.14.3 Description

The spherical dihedral style uses the potential:

\[ E(\phi, \theta_1, \theta_2) = \sum_{i=1}^{N} C_i \Phi_i(\phi) \Theta_{1i}(\theta_1) \Theta_{2i}(\theta_2) \]

\[ \Phi_i(\phi) = u_i - \cos((\phi - a_i) K_i) \]

\[ \Theta_{1i}(\theta_1) = v_i - \cos((\theta_1 - b_i) L_i) \]

\[ \Theta_{2i}(\theta_2) = w_i - \cos((\theta_2 - c_i) M_i) \]

For this dihedral style, the energy can be any function that combines the 4-body dihedral-angle (\( \phi \)) and the two 3-body bond-angles (\( \theta_1, \theta_2 \)). For this reason, there is usually no need to define 3-body “angle” forces separately for the atoms participating in these interactions. It is probably more efficient to incorporate 3-body angle forces into the dihedral interaction even if it requires adding additional terms to the expansion (as was done in the second example). A careful choice of parameters can prevent singularities that occur with traditional force-fields whenever \( \theta_1 \) or \( \theta_2 \) approach 0 or 180 degrees.

The last example above corresponds to an interaction with a single energy minima located near \( \phi = 93.9, \theta_1 = 74.4, \theta_2 = 48.1 \) degrees, and it remains numerically stable at all angles (\( \phi, \theta_1, \theta_2 \)). In this example, the coefficients 49.1, and 25.2 can be physically interpreted as the harmonic spring constants for \( \theta_1 \) and \( \theta_2 \) around their minima. The coefficient 69.3 is the harmonic spring constant for \( \phi \) after division by \( \sin(74.4)^2 \sin(48.1) \) (the minima positions for \( \theta_1 \) and \( \theta_2 \)).

The following coefficients must be defined for each dihedral type via the `dihedral_coeff` command as in the example above, or in the Dihedral Coeffs section of a data file read by the `read_data` command:

- \( n \) (integer >= 1)
- \( C_1 \) (energy)
- \( K_1 \) (typically an integer)
- \( a_1 \) (degrees)
- \( u_1 \) (typically 0.0 or 1.0)
- \( L_1 \) (typically an integer)
- \( b_1 \) (degrees, typically 0.0 or 90.0)
- \( v_1 \) (typically 0.0 or 1.0)
- \( M_1 \) (typically an integer)
- \( c_1 \) (degrees, typically 0.0 or 90.0)
- \( w_1 \) (typically 0.0 or 1.0)
  
  ... [\text{...}]
- \( C_n \) (energy)
- \( K_n \) (typically an integer)
- \( a_n \) (degrees)
22.14.4 Restrictions

This dihedral style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the Build package doc page for more info.

22.16.3 Description

The table and table/cut dihedral styles create interpolation tables of length Ntable from dihedral potential and derivative values listed in a file(s) as a function of the dihedral angle “phi”. The files are read by the dihedral_coeff command. For dihedral style table/cut additionally an analytic cutoff that is quadratic in the bond-angle (theta) is applied in order to regularize the dihedral interaction.

The interpolation tables are created by fitting cubic splines to the file values and interpolating energy and derivative values at each of Ntable dihedral angles. During a simulation, these tables are used to interpolate energy and force values on individual atoms as needed. The interpolation is done in one of 2 styles: linear or spline.

For the linear style, the dihedral angle (phi) is used to find 2 surrounding table values from which an energy or its derivative is computed by linear interpolation.

For the spline style, cubic spline coefficients are computed and stored at each of the Ntable evenly-spaced values in the interpolated table. For a given dihedral angle (phi), the appropriate coefficients are chosen from this list, and a cubic polynomial is used to compute the energy and the derivative at this angle.

For dihedral style table the following coefficients must be defined for each dihedral type via the dihedral_coeff command as in the example above.

- filename
- keyword

The filename specifies a file containing tabulated energy and derivative values. The keyword specifies which section of the file to read. The format of this file is the same for both dihedral styles and described below.

For dihedral style table/cut the following coefficients must be defined for each dihedral type via the dihedral_coeff command as in the example above.

- style (aat)
- cutoff prefactor
- cutoff angle1
- cutoff angle2
- filename
- keyword

The cutoff dihedral style uses a tabulated dihedral interaction with a cutoff function:

\[
\begin{align*}
    f(\theta) &= K & \theta < \theta_1 \\
    f(\theta) &= K \left( 1 - \frac{(\theta - \theta_1)^2}{(\theta_2 - \theta_1)^2} \right) & \theta_1 < \theta < \theta_2
\end{align*}
\]
The cutoff specifies a prefactor to the cutoff function. While this value would ordinarily equal 1 there may be situations where the value should change.

The cutoff $\theta_1$ specifies the angle (in degrees) below which the dihedral interaction is unmodified, i.e. the cutoff function is 1.

The cutoff function is applied between $\theta_1$ and $\theta_2$, which is the angle at which the cutoff function drops to zero. The value of zero effectively “turns off” the dihedral interaction.

The filename specifies a file containing tabulated energy and derivative values. The keyword specifies which section of the file to read. The format of this file is the same for both dihedral styles and described below.

The format of a tabulated file is as follows (without the parenthesized comments). It can begin with one or more comment or blank lines.

```
# Table of the potential and its negative derivative
DIH_TABLE1 (keyword is the first text on line)
N 30 DEGREES (N, NOF, DEGREES, RADIANS, CHECKU/F)
(blank line)
1 -168.0 -1.40351172223 0.0423346818422
2 -156.0 -1.70447981034 0.00811786522531
3 -144.0 -1.62956100432 -0.0184129719987
... 30 180.0 -0.707106781187 0.0719306095245
```

```
# Example 2: table of the potential. Forces omitted
DIH_TABLE2
N 30 NOF CHECKU testU.dat CHECKF testF.dat

1 -168.0 -1.40351172223
2 -156.0 -1.70447981034
3 -144.0 -1.62956100432
... 30 180.0 -0.707106781187
```

A section begins with a non-blank line whose first character is not a “#”; blank lines or lines starting with “#” can be used as comments between sections. The first line begins with a keyword which identifies the section. The line can contain additional text, but the initial text must match the argument specified in the `dihedral_coeff` command. The next line lists (in any order) one or more parameters for the table. Each parameter is a keyword followed by one or more numeric values.

Following a blank line, the next N lines list the tabulated values. On each line, the first value is the index from 1 to N, the second value is the angle value, the third value is the energy (in energy units), and the fourth is -dE/d(\phi) also in energy units. The third term is the energy of the 4-atom configuration for the specified angle. The fourth term (when present) is the negative derivative of the energy with respect to the angle (in degrees, or radians depending on whether the user selected DEGREES or RADIANS). Thus the units of the last term are still energy, not force. The dihedral angle values must increase from one line to the next.

Dihedral table splines are cyclic. There is no discontinuity at 180 degrees (or at any other angle). Although in the examples above, the angles range from -180 to 180 degrees, in general, the first angle in the list can have any value (positive, zero, or negative). However the range of angles represented in the table must be strictly less than 360 degrees (2\pi radians) to avoid angle overlap. (You may not supply entries in the table for both 180 and -180, for example.) If the user’s table covers only a narrow range of dihedral angles, strange numerical behavior can occur in the large remaining gap.

22.16. dihedral_style table/cut command
Parameters:

The parameter “N” is required and its value is the number of table entries that follow. Note that this may be different than the N specified in the dihedral_style table command. Let Ntable be the number of table entries requested dihedral_style command, and let Nfile be the parameter following “N” in the tabulated file (“30” in the sparse example above). What LAMMPS does is a preliminary interpolation by creating splines using the Nfile tabulated values as nodal points. It uses these to interpolate as needed to generate energy and derivative values at Ntable different points (which are evenly spaced over a 360 degree range, even if the angles in the file are not). The resulting tables of length Ntable are then used as described above, when computing energy and force for individual dihedral angles and their atoms. This means that if you want the interpolation tables of length Ntable to match exactly what is in the tabulated file (with effectively no preliminary interpolation), you should set Ntable = Nfile. To insure the nodal points in the user’s file are aligned with the interpolated table entries, the angles in the table should be integer multiples of 360/Ntable degrees, or 2*PI/Ntable radians (depending on your choice of angle units).

The optional “NOF” keyword allows the user to omit the forces (negative energy derivatives) from the table file (normally located in the fourth column). In their place, forces will be calculated automatically by differentiating the potential energy function indicated by the third column of the table (using either linear or spline interpolation).

The optional “DEGREES” keyword allows the user to specify angles in degrees instead of radians (default). The optional “RADIANS” keyword allows the user to specify angles in radians instead of degrees. (Note: This changes the way the forces are scaled in the fourth column of the data file.)

The optional “CHECKU” keyword is followed by a filename. This allows the user to save all of the Ntable different entries in the interpolated energy table to a file to make sure that the interpolated function agrees with the user’s expectations. (Note: You can temporarily increase the Ntable parameter to a high value for this purpose. “Ntable” is explained above.)

The optional “CHECKF” keyword is analogous to the “CHECKU” keyword. It is followed by a filename, and it allows the user to check the interpolated force table. This option is available even if the user selected the “NOF” option.

Note that one file can contain many sections, each with a tabulated potential. LAMMPS reads the file section by section until it finds one that matches the specified keyword.

Styles with a gpu, intel, kk, omp, or opt suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the -suffix command-line switch when you invoke LAMMPS, or you can use the suffix command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

22.16.4 Restart, fix_modify, output, run start/stop, minimize info

These dihedral styles write the settings for the “dihedral_style table” or “dihedral_style table/cut” command to binary restart files, so a dihedral_style command does not need to specified in an input script that reads a restart file. However, the coefficient information loaded from the table file(s) is not stored in the restart file, since it is tabulated in the potential files. Thus, suitable dihedral_coeff commands do need to be specified in the restart input script after reading the restart file.
22.16.5 Restrictions

The table dihedral style can only be used if LAMMPS was built with the MOLECULE package. The table/cut dihedral style can only be used if LAMMPS was built with the EXTRA-MOLECULE package. See the Build package doc page for more info.

dihedral_coeff

22.16.7 Default

none

22.17 dihedral_style zero command

22.17.1 Syntax

```
dihedral_style zero [nocoeff]
```

22.17.2 Examples

```
dihedral_style zero
dihedral_style zero nocoeff
dihedral_coeff *
```

22.17.3 Description

Using a dihedral style of zero means dihedral forces and energies are not computed, but the geometry of dihedral quadruplets is still accessible to other commands.

As an example, the compute dihedral/local command can be used to compute the theta values for the list of quadruplets of dihedral atoms listed in the data file read by the read_data command. If no dihedral style is defined, this command cannot be used.

The optional nocoeff flag allows to read data files with a DihedralCoeff section for any dihedral style. Similarly, any dihedral_coeff commands will only be checked for the dihedral type number and the rest ignored.

Note that the dihedral_coeff command must be used for all dihedral types, though no additional values are specified.

23.1 improper_style class2 command

Accelerator Variants: class2/omp, class2/kk

23.1.1 Syntax

\texttt{improper_style class2}

23.1.2 Examples

\begin{verbatim}
improper_style class2
improper_coeff 1 100.0 0
improper_coeff * aa 0.0 0.0 0.0 115.06 130.01 115.06
\end{verbatim}

23.1.3 Description

The class2 improper style uses the potential

\[ E = E_i + E_{aa} \]
\[ E_i = K \left( \chi_{ijkl} + \chi_{kjli} + \chi_{ljik} - \chi_0 \right)^2 \]
\[ E_{aa} = M_1 (\theta_{ijk} - \theta_1)(\theta_{kjl} - \theta_3) + M_2 (\theta_{ijk} - \theta_1)(\theta_{ijl} - \theta_2) + M_3 (\theta_{ijl} - \theta_2)(\theta_{kjl} - \theta_3) \]

where \( E_i \) is the improper term and \( E_{aa} \) is an angle-angle term. The 3 \( \chi \) terms in \( E_i \) are an average over 3 out-of-plane angles.

The 4 atoms in an improper quadruplet (listed in the data file read by the \texttt{read_data} command) are ordered I,J,K,L. \( \chi_{ijkl} \) refers to the angle between the plane of I,J,K and the plane of J,K,L, and the bond JK lies in both planes. Similarly for \( \chi_{kjli} \) and \( \chi_{ljik} \). Note that atom J appears in the common bonds (JI, JK, JL) of all 3 X terms. Thus J (the second atom in the quadruplet) is the atom of symmetry in the 3 \( \chi \) angles.

The subscripts on the various \( \theta \)s refer to different combinations of 3 atoms (I,J,K,L) used to form a particular angle. E.g. \( \theta_{ijkl} \) is the angle formed by atoms I,J,L with J in the middle. \( \theta_1, \theta_2, \theta_3 \) are the equilibrium positions of those angles. Again, atom J (the second atom in the quadruplet) is the atom of symmetry in the theta angles, since it is always the center atom.
Since atom J is the atom of symmetry, normally the bonds J-I, J-K, J-L would exist for an improper to be defined between the 4 atoms, but this is not required.

See (Sun) for a description of the COMPASS class2 force field.

Coefficients for the $E_i$ and $E_{aa}$ formulas must be defined for each improper type via the `improper_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands.

These are the 2 coefficients for the $E_i$ formula:

- $K$ (energy)
- $\chi_0$ (degrees)

$\chi_0$ is specified in degrees, but LAMMPS converts it to radians internally; hence $K$ is effectively energy per radian$^2$.

For the $E_{aa}$ formula, each line in a `improper_coeff` command in the input script lists 7 coefficients, the first of which is $aa$ to indicate they are AngleAngle coefficients. In a data file, these coefficients should be listed under a `AngleAngle Coeffs` heading and you must leave out the $aa$, i.e. only list 6 coefficients after the improper type.

- $aa$
- $M_1$ (energy)
- $M_2$ (energy)
- $M_3$ (energy)
- $\theta_1$ (degrees)
- $\theta_2$ (degrees)
- $\theta_3$ (degrees)

The $\theta$ values are specified in degrees, but LAMMPS converts them to radians internally; hence the various $M$ are effectively energy per radian$^2$.

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the Accelerator packages page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the Build package page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix command-line switch` when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 23.1.4 Restrictions

This improper style can only be used if LAMMPS was built with the CLASS2 package. See the Build package doc page for more info.
23.1.5 Related commands

improper_coeff

23.1.6 Default

23.2 improper_style cossq command

Accelerator Variants: cossq/omp

23.2.1 Syntax

improper_style cossq

23.2.2 Examples

improper_style cossq
improper_coeff 1 4.0 0.0

23.2.3 Description

The cossq improper style uses the potential

\[ E = \frac{1}{2} K \cos^2 (\chi - \chi_0) \]

where \( \chi \) is the improper angle, \( \chi_0 \) is its equilibrium value, and \( K \) is a prefactor.

If the 4 atoms in an improper quadruplet (listed in the data file read by the read_data command) are ordered I,J,K,L then \( \chi \) is the angle between the plane of I,J,K and the plane of J,K,L. Alternatively, you can think of atoms J,K,L as being in a plane, and atom I above the plane, and \( \chi \) as a measure of how far out-of-plane I is with respect to the other 3 atoms.

Note that defining 4 atoms to interact in this way, does not mean that bonds necessarily exist between I-J, J-K, or K-L, as they would in a linear dihedral. Normally, the bonds I-J, I-K, I-L would exist for an improper to be defined between the 4 atoms.

The following coefficients must be defined for each improper type via the improper_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- \( K \) (energy)
- \( \chi_0 \) (degrees)

\section{improper_style cvff command}

Accelerator Variants: \texttt{cvff/intel}, \texttt{cvff/omp}

\subsection{23.3.1 Syntax}

\begin{verbatim}
improper_style cvff
\end{verbatim}

\subsection{23.3.2 Examples}

\begin{verbatim}
improper_style cvff
improper_coeff 1 80.0 -1 4
\end{verbatim}
23.3.3 Description

The *cvff* improper style uses the potential

\[ E = K[1 + d \cos(n\phi)] \]

where \( \phi \) is the improper dihedral angle.

If the 4 atoms in an improper quadruplet (listed in the data file read by the `read_data` command) are ordered I,J,K,L then the improper dihedral angle is between the plane of I,J,K and the plane of J,K,L. Note that because this is effectively a dihedral angle, the formula for this improper style is the same as for `dihedral_style harmonic`.

Note that defining 4 atoms to interact in this way, does not mean that bonds necessarily exist between I-J, J-K, or K-L, as they would in a linear dihedral. Normally, the bonds I-J, I-K, I-L would exist for an improper to be defined between the 4 atoms.

The following coefficients must be defined for each improper type via the `improper_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- \( K \) (energy)
- \( d \) (+1 or -1)
- \( n \) (0,1,2,3,4,6)

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Accelerator packages` page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Accelerator packages` page for more instructions on how to use the accelerated styles effectively.

23.3.4 Restrictions

This improper style can only be used if LAMMPS was built with the MOLECULE package. See the `Build package` doc page for more info.

improper_style distharm
```

#### 23.5.2 Examples

```text
improper_style distharm
improper_coeff 1 25.0 0.5
```

#### 23.5.3 Description

The `distharm` improper style uses the potential

\[
E = K (d - d_0)^2
\]

where \( d \) is the oriented distance between the central atom and the plane formed by the other three atoms. If the 4 atoms in an improper quadruplet (listed in the data file read by the `read_data` command) are ordered I,J,K,L then the L-atom is assumed to be the central atom. Note that this is different from the convention used in the improper_style distance. The distance \( d \) is oriented and can take on negative values. This may lead to unwanted behavior if \( d_0 \) is not equal to zero.

The following coefficients must be defined for each improper type via the improper_coeff command as in the example above, or in the data file or restart files read by the read_data or read_restart commands:

- \( K \) (energy/distance^2)
• \(d_0\) (distance)

### 23.8 improper_style hybrid command

#### 23.8.1 Syntax

```
improper_style hybrid style1 style2 ...
```

• style1,style2 = list of one or more improper styles

#### 23.8.2 Examples

```
improper_style hybrid harmonic helix
improper_coeff 1 harmonic 120.0 30
improper_coeff 2 cvff 20.0 -1 2
```
23.8.3 Description

The *hybrid* style enables the use of multiple improper styles in one simulation. An improper style is assigned to each improper type. For example, impropers in a polymer flow (of improper type 1) could be computed with a *harmonic* potential and impropers in the wall boundary (of improper type 2) could be computed with a *cvff* potential. The assignment of improper type to style is made via the `improper_coeff` command or in the data file.

In the improper_coeff command, the first coefficient sets the improper style and the remaining coefficients are those appropriate to that style. In the example above, the 2 improper_coeff commands would set impropers of improper type 1 to be computed with a *harmonic* potential with coefficients 120.0, 30 for K,, $\chi_0$. Improper type 2 would be computed with a *cvff* potential with coefficients 20.0, -1, 2 for K, d, and n, respectively.

If improper coefficients are specified in the data file read via the `read_data` command, then the same rule applies. E.g. “harmonic” or “cvff”, must be added after the improper type, for each line in the “Improper Coeffs” section, e.g.

```
Improper Coeffs

  1 harmonic 120.0 30
  2 cvff 20.0 -1 2
   ...
```

If `class2` is one of the improper hybrid styles, the same rule holds for specifying additional AngleAngle coefficients either via the input script or in the data file. I.e. `class2` must be added to each line after the improper type. For lines in the AngleAngle Coeffs section of the data file for dihedral types that are not `class2`, you must use an improper style of `skip` as a placeholder, e.g.

```
AngleAngle Coeffs

  1 skip
  2 class2 0.0 0.0 0.0 115.06 130.01 115.06
   ...
```

Note that it is not necessary to use the improper style `skip` in the input script, since AngleAngle coefficients need not be specified at all for improper types that are not `class2`.

An improper style of `none` can be specified as the second argument to the improper_coeff command, if you desire to turn off certain improper types.

23.8.4 Restrictions

This improper style can only be used if LAMMPS was built with the MOLECULE package. See the *Build package* doc page for more info.

Unlike other improper styles, the hybrid improper style does not store improper coefficient info for individual sub-styles in a *binary restart files*. Thus when restarting a simulation from a restart file, you need to re-specify improper_coeff commands.
23.8.5 Related commands

improper_coeff

23.8.6 Default

none

23.9 improper_style inversion/harmonic command

23.9.1 Syntax

\begin{verbatim}
improper_style inversion/harmonic
\end{verbatim}

23.9.2 Examples

\begin{verbatim}
improper_style inversion/harmonic
improper_coeff 1 18.776340 0.000000
\end{verbatim}

23.9.3 Description

The \textit{inversion/harmonic} improper style follows the Wilson-Decius out-of-plane angle definition and uses an harmonic potential:

\[ E = K (\omega - \omega_0)^2 \]

where \( K \) is the force constant and \( \omega \) is the angle evaluated for all three axis-plane combinations centered around the atom \( I \). For the IL axis and the IJK plane \( \omega \) looks as follows:

Note that the \textit{inversion/harmonic} angle term evaluation differs to the \textit{improper_umbrella} due to the cyclic evaluation of all possible angles \( \omega \).
The following coefficients must be defined for each improper type via the `improper_coeff` command as in the example above, or in the data file or restart files read by the `read_data` or `read_restart` commands:

- $K$ (energy)
- $\omega_0$ (degrees)

If $\omega_0 = 0$ the potential term has a single minimum for the planar structure. Otherwise it has two minima at $\pm\omega_0$, with a barrier in between.

### 23.9.4 Restrictions

This improper style can only be used if LAMMPS was built with the MOFF package. See the `Build package` doc page for more info.

### 23.9.5 Related commands

`improper_coeff`

### 23.9.6 Default

`none`

### 23.10 improper_style none command

#### 23.10.1 Syntax

```
improper_style none
```

#### 23.10.2 Examples

```
improper_style none
```

#### 23.10.3 Description

Using an improper style of none means improper forces and energies are not computed, even if quadruplets of improper atoms were listed in the data file read by the `read_data` command.

See the `improper_style zero` command for a way to calculate improper statistics, but compute no improper interactions.
23.10.4 Restrictions

none

23.10.5 Related commands

*improper_style* zero

23.10.6 Default

none

23.11 improper_style ring command

Accelerator Variants: *ring omp*

23.11.1 Syntax

```
improper_style ring
```

23.11.2 Examples

```
improper_style ring
improper_coeff 1 8000 70.5
```

23.11.3 Description

The *ring* improper style uses the potential

\[ E = \frac{1}{6} K (\Delta_{ijl} + \Delta_{ijk} + \Delta_{kjl})^6 \]

\[ \Delta_{ijl} = \cos \theta_{ijl} - \cos \theta_0 \]

\[ \Delta_{ijk} = \cos \theta_{ijk} - \cos \theta_0 \]

\[ \Delta_{kjl} = \cos \theta_{kjl} - \cos \theta_0 \]

where \( K \) is a prefactor, \( \theta \) is the angle formed by the atoms specified by \((i,j,k,l)\) indices and \( \theta_0 \) its equilibrium value.

If the 4 atoms in an improper quadruplet (listed in the data file read by the *read_data* command) are ordered \(i,j,k,l\) then \( \theta_{ijl} \) is the angle between atoms \(i,j,l\), \( \theta_{ijk} \) is the angle between atoms \(i,j,k\), and \( \theta_{kjl} \) is the angle between atoms \(j,k,l\). If the quadruplet consists of \(i,j,k\) and \(l\) then \( \theta_{ijl} \) is the angle between \(i,j\) and \(l\).

The “ring” improper style implements the improper potential introduced by Destree et al., in Equation (9) of *Destree*. This potential does not affect small amplitude vibrations but is used in an ad-hoc way to prevent the onset of accidentally large amplitude fluctuations leading to the occurrence of a planar conformation of the three bonds \(i-j, j-k\) and \(j-l\), an intermediate conformation toward the chiral inversion of a methine carbon. In the “Impropers” section of data file four atoms: \(i, j, k\) and \(l\) are specified with \(i,j\) and \(l\) lying on the backbone of the chain and \(k\) specifying the chirality of \(j\).

The following coefficients must be defined for each improper type via the *improper_coeff* command as in the example above, or in the data file or restart files read by the *read_data* or *read_restart* commands:
• $K$ (energy)
• $\theta_0$ (degrees)

Styles with a `gpu`, `intel`, `kk`, `omp`, or `opt` suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the `Accelerator packages` page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the `Build package` page for more info.

You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the `Accelerator packages` page for more instructions on how to use the accelerated styles effectively.

### 23.11.4 Restrictions

This improper style can only be used if LAMMPS was built with the MOLECULE package. See the `Build package` doc page for more info.

### 23.11.5 Related commands

`improper_coeff`

### 23.12 improper_style sqdistharm command

#### 23.12.1 Syntax

```
improper_style sqdistharm
```

#### 23.12.2 Examples

```
improper_style sqdistharm
improper_coeff 1 50.0 0.1
```
23.12.3 Description

The \textit{sqdistharm} improper style uses the potential

\[ E = K(d^2 - d_0^2)^2 \]

where \( d \) is the distance between the central atom and the plane formed by the other three atoms. If the 4 atoms in an improper quadruplet (listed in the data file read by the \textit{read_data} command) are ordered I,J,K,L then the L-atom is assumed to be the central atom. Note that this is different from the convention used in the \textit{improper_style} distance.

The following coefficients must be defined for each improper type via the \textit{improper_coeff} command as in the example above, or in the data file or restart files read by the \textit{read_data} or \textit{read_restart} commands:

- \( K \) (energy/distance\(^4\))
- \( d_0^2 \) (distance\(^2\))

Note that \( d_0^2 \) (in units distance\(^2\)) has be provided and not \( d_0 \).

23.12.4 Restrictions

This improper style can only be used if LAMMPS was built with the MOLECULE package. See the \textit{Build package} doc page for more info.

23.12.5 Related commands

\textit{improper_coeff}

23.12.6 Default

none

23.13 \textit{improper_style umbrella} command

Accelerator Variants: \textit{umbrella/omp}

23.13.1 Syntax

\begin{verbatim}
improper_style umbrella
\end{verbatim}
23.13.2 Examples

improper_style umbrella
improper_coeff 1 100.0 180.0

23.13.3 Description

The *umbrella* improper style uses the following potential, which is commonly referred to as a classic inversion and used in the *DREIDING* force field:

\[
E = \frac{1}{2} K \left( \frac{1}{\sin \omega_0} \right)^2 \left( \cos \omega - \cos \omega_0 \right)^2, \quad \omega_0 \neq 0^\circ
\]

\[
E = K (1 - \cos \omega), \quad \omega_0 = 0^\circ
\]

where \( K \) is the force constant and \( \omega \) is the angle between the IL axis and the IJK plane:

If \( \omega_0 = 0 \) the potential term has a minimum for the planar structure. Otherwise it has two minima at \( \omega + / - \omega_0 \), with a barrier in between.

See *(Mayo)* for a description of the DREIDING force field.

The following coefficients must be defined for each improper type via the *improper_coeff* command as in the example above, or in the data file or restart files read by the *read_data* or *read_restart* commands:

- \( K \) (energy)
- \( \omega_0 \) (degrees)

Styles with a *gpu*, *intel*, *kk*, *omp*, or *opt* suffix are functionally the same as the corresponding style without the suffix. They have been optimized to run faster, depending on your available hardware, as discussed on the *Accelerator packages* page. The accelerated styles take the same arguments and should produce the same results, except for round-off and precision issues.

These accelerated styles are part of the GPU, INTEL, KOKKOS, OPENMP and OPT packages, respectively. They are only enabled if LAMMPS was built with those packages. See the *Build package* page for more info.
You can specify the accelerated styles explicitly in your input script by including their suffix, or you can use the `-suffix` command-line switch when you invoke LAMMPS, or you can use the `suffix` command in your input script.

See the Accelerator packages page for more instructions on how to use the accelerated styles effectively.

### 23.13.4 Restrictions

This improper style can only be used if LAMMPS was built with the MOLECULE package. See the Build package doc page for more info.

### 23.13.5 Related commands

`improper_coeff`

### 23.13.6 Default

`none`

### 23.14 improper_style zero command

#### 23.14.1 Syntax

```
improper_style zero [nocoeff]
```

#### 23.14.2 Examples

```
improper_style zero
improper_style zero nocoeff
improper_coeff *
```

#### 23.14.3 Description

Using an improper style of zero means improper forces and energies are not computed, but the geometry of improper quadruplets is still accessible to other commands.

As an example, the `compute improper/local` command can be used to compute the chi values for the list of quadruplets of improper atoms listed in the data file read by the `read_data` command. If no improper style is defined, this command cannot be used.

The optional `nocoeff` flag allows to read data files with a ImproperCoeff section for any improper style. Similarly, any improper_coeff commands will only be checked for the improper type number and the rest ignored.

Note that the `improper_coeff` command must be used for all improper types, though no additional values are specified.

Web Browser Compatibility

The HTML version of the manual makes use of advanced features present in “modern” web browsers. This can lead to incompatibilities with older web browsers (released more than 4 years ago) and specific vendor browsers (e.g. Internet Explorer on Windows; Microsoft Edge works well though) where parts of the pages are not rendered as expected (e.g. the layout is broken or mathematical expressions not typeset). In that case we recommend to install/use a different/newer web browser or use the PDF version of the manual.
